Nursing Infants with Asses' Milk.—In recent years, in France, conscientious efforts have been made to ascertain the principal causes of the loss of population, and it has been demonstrated by numerous facts that one of these causes consists in the physical degeneration induced by deficiency of alimentation in infancy; and the most eminent physicians of Paris, and the Director of Public Assistance, have endeavored to modify and improve the system of nutrition in the public charitable institutions, providing for recently born children lactation adequate to the necessities of the temperament and constitution.

In the Hospital for Infants' Diseases, situated in Sabres Street, there exists a section for rickety boys and girls, whose miserable aspect produces an impression of pain upon the mind—unfortunate beings who have inherited the organic vices of their parents, and who suffer from anæmia's cruel tortures.

The administration of the hospital is arranged in two separated pavilions, where there is much ventilation, with large windows that look out upon a garden, and whose walls have double rows of willow cradles perfectly equipped. The newly born receive here the personal care of the establishment, beginning with being weighed in the balance the same day they make their appearance, the operation being frequently repeated, almost every month, in order to determine with exactness the development of the child. The little one is subjected to an especially nutritious diet of the most tonic kind, if it had been previously fed from a refractory goat liable to convey contagious germs, it having been found by experiment that the milk of this animal, although possessing nutritive principles of the most salutary kind, presents the inconvenience of communicating by absorption the effects of those nervous accidents to which the goat is subject.

The public charities of Paris, advised by the wise doctors of medicine, have substituted for the milk of goats that of the ass, and have installed an ample yard near the pavilion of the rickety and scrofulous children, which is only separated by a short, covered passageway. Nothing is more picturesque than the spectacle of the lactation of the babes in this enclosure every morning.

The nurses, dressed in dark gowns with white caps and aprons, each carrying a child on the right arm and a little seat in the left hand, present themselves in exact turn to the women who have charge of the animals, and they hold the child, applying its lips to the teats of the docile animal. The children suck with avidity the liquid nutriment, which is fresh and of agreeable taste.

The Administration of Public Assistance of Paris has calculated that one young ass is able to lactate abundantly for a space of nine or ten months, and when this period has passed they are sold and replaced by others. It is well known that the milk of asses, by its vivifying qualities and nutritious principles, assimilates in a great degree the milk of the nurse, and these disinherited and sick children, enjoying its beneficial effects by its permanent and methodical use, are restored little by little to health and vigor.—*Scientific American,* March 16, 1889, from *La Ilustracion Espanola.*

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 12 TO MARCH 18, 1889.

By direction of the Secretary of War, Jedediah H. Baxter, *Chief Medical Purveyor,* will proceed to New York City on public business connected with the Medical Department, and, on completion thereof, return to his station in this city.—Par. 18, *S. O. 57, A. G. O., Washington,* March 11, 1889.

By direction of the Secretary of War, Robert W. Shufeldt, *Captain and Assistant Surgeon,* having been found incapacitated for active service by an Army Retiring Board, is granted leave of absence until further orders, on account of disability.—Par. 7, *S. O. 56, A. G. O., Washington,* March 9, 1889.

By direction of the Secretary of War, Richard W. Johnson, *Captain and Assistant Surgeon,* is relieved from duty at San Carlos, Arizona, and will report in person to the commanding officer Whipple Barracks, Arizona, for duty at that station.—Par. 15, *S. O. 57, A. G. O., Washington,* March 11, 1889.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY, FOR THE WEEK ENDING MARCH 16, 1889.

Hesler, Frederick A., *Assistant Surgeon.*—Detached from the Naval Hospital, New York, and ordered for examination preliminary to promotion.

Ogden, Frederick N., *Assistant Surgeon.*—Ordered to the Receiving-ship "St. Louis," Navy Yard, League Island.

Bryant, Patrick H., *Assistant Surgeon.*—Detached from the Receiving-ship "St. Louis," and ordered to the Naval Hospital, Chelsea, Massachusetts.

ORIGINAL LECTURES.

CÆSAREAN SECTION FOR CANCER OF THE CERVIX.

A Clinical Lecture delivered at the Hospital of the University of Pennsylvania, March 13, 1889.

BY WILLIAM GOODELL, M.D.,
PROFESSOR OF GYNECOLOGY.

GENTLEMEN: I shall to-day perform the operation of Cæsarean section before you, and as I shall not be able to talk much during the operation, I shall say what I have to say while the patient is being etherized.

I am emboldened to do this operation before you for this reason: At the beginning of our course, six months ago, I took a new departure, and up to the present time my son and I have performed abdominal section twenty-three times, either in this amphitheatre or before the ward classes. Of this number we have lost only one from septicæmia, and in that case death was almost a foregone conclusion. It was a desperate case, with rotten pus in both tubes and both ovaries, which were universally adherent and could not be wholly removed. We have had one death from shock in a case of large sarcoma of the womb, removed by supra-vaginal hysterectomy. We have had a third death, but not, however, from the operation. If in this case I had made a complete diagnosis, perhaps I would not have operated. She had mental hebetude, very marked loss of memory, a hesitating speech, and many nerve-symptoms which I thought were hysterical, but which were really due to some obscure cerebro-spinal lesion. She had severe groin-aches and painful locomotion, which were, and I think correctly, referred to very marked disease of the uterine appendages. I removed the ovaries and tubes, which were enlarged, adherent, and contained pus. The patient recovered from the operation, and did very well for over two weeks, then paresis set in, followed by loss of control over the sphincters, and she died in the fourth week. An autopsy was not permitted, and I am therefore left in doubt as to the character of the brain lesion, but I think it was the result of specific disease. These are all the fatal cases that we have had, and only one can be laid to blood-poisoning.

The patient on whom I shall operate to-day is a white woman, aged thirty-two years. She married when a little over fourteen years of age, and has had eight children and four miscarriages, the last one of twins. In February of last year she found that she was losing blood per vaginam, but neglected to have anything done until some months later. When she came under observation, it was found that she had advanced cancer of the cervix. This was curetted and burned with the actual cautery by my son in October last. Since then the hemorrhages have ceased until very recently. At the time of the curetting she was pregnant. but the condition escaped recognition until two weeks later, when the movements of the child were felt by her. We have had to depend upon the sign of quickening in determining the age of the fœtus, and, according to my calculation, it is within two weeks of the full nine months; but this is a rough and untrustworthy datum.

This operation is necessary because the cervix is hardened and thickened by dense masses of cancer, and is firmly fused to bladder and rectum. In all probability it would be impossible for the cervix to dilate sufficiently to allow the passage of a living child. The result would undoubtedly be death to the child and death to the mother. So we are driven to the operation to save the life of the child and to prolong that of the mother.

I think it wisest to do the operation before the period of gestation is fully completed, for then we can choose our own time, and besides that, her hemorrhages have started up again, which will weaken her. The only objection is, that the canalization of the cervix caused by labor has not, of course, taken place. It is important that the cervical canal should be somewhat dilated, in order to afford an avenue of escape for the lochial discharges. After completing the operation, I shall do this artificially, using, if necessary, my uterine dilators.

According to my diagnosis, we have here a breech presentation with the back of the child to the right. I hear the fœtal heart sounds very plainly on the right side. I do not understand how it is that I hear them so distinctly with the right side of the child uppermost.

The patient has shown a good deal of pluck in looking forward to this operation. This is mainly due to the fact that she has been in the hospital for a couple of months, and has had an opportunity of seeing a number of cases of abdominal section for large tumors followed by recovery. She has made one stipulation, that I should baptize the child as soon as it is born. I wish to say one word here in this relation: Always respect the religious tenets of your patients, no matter what your own may be. So I make it an inflexible rule to ask a woman in labor, whom I may be attending, whether she wishes me to baptize the infant if its life is in danger, and I always accede to her wishes. Our patient has given me two names. If it turns out a boy, it is to be named Owen; if a girl, Sarah Agnes.

What are the statistics of this operation? The old Cæsarean section was a very dangerous operation, the great majority of cases perishing. This was largely due to the fact that the operation was delayed too long, until time, ergot, and the forceps had been tried. When antisepsis was used, and the operation was undertaken a short time after labor set in, the results were better, although the mortality still remained very high until Sänger, of Leipsic, suggested a method of operating, since which the success has been marvellously improved. Dr. Harris, who has honored us by his presence to-day, and who is one of our most accurate and

best statisticians, tells me that there have been performed 163 cases of the Sänger operation, with 45 deaths. In this country the statistics are not so favorable, there having been 26 cases with 16 deaths. One reason that the Sänger operation is more successful than the old Cæsarean section, is because two sets of sutures are put in, bringing the uterine walls and the edges of the peritoneum into close contact. This formerly was not done. Another reason for the present success is, that we now recognize the great importance of aseptic and antiseptic precautions. In closing the incision through the uterine wall I shall employ two sets of sutures. First, a set of deep sutures introduced about half an inch from the edge of the wound and passing down to the mucosa but not penetrating it. The object of not going through the mucous membrane is of course to avoid the passage of septic material from the uterine cavity to the peritoneal cavity through the suture opening. In tying the deep sutures I shall take care to invert the serous covering of the uterus so as to secure close coaptation. This will also be favored by the second set of stitches consisting of the Lembert suture superficially applied. In this way we get that perfect union which is essential to success.

We have prepared the patient and instruments with scrupulous care to avoid the introduction of septic matter, and I shall now proceed with the operation, making an incision from above the umbilicus to near the pubes, controlling hemorrhage by hemostatic forceps. I next open the peritoneum and at once come upon the uterus. There are two ways by which we may now proceed. In the first place, we may open the uterus *in situ*, the abdominal walls being closely pressed against the uterus to prevent the entrance of fluids into the peritoneal cavity. The child is then removed and the uterus brought through the abdominal incision. In the second method, the uterus is brought through the abdominal wound and then opened outside of the body. I shall adopt the former plan as it will not need so long an abdominal incision.

The uterus was then opened, an incision of about five inches being made. The escape of the liquor amnii was accompanied by the protrusion of the right arm of the child, which, as had been diagnosticated, presented by the breech. The head was in the left hypochondriac region and the back of the child toward the right. The head was brought to the uterine opening and delivered, the rest of the body following without difficulty. The cord was compressed with hemostatic forceps and cut. The child (a male) was then given to Dr. Barton Cooke Hirst and in a few minutes was crying lustily.

The uterus was next brought outside of the abdomen and the peritoneal cavity packed with sponges. The left ovary and tube were seen attached to the uterus. A rubber tube was secured around the cervix and the placenta gently detached and removed. A sponge was placed temporarily in the uterine cavity and the deep sutures, fourteen in number, inserted. The sponge was then removed and the deep sutures tied. The superficial sutures, consisting of seventeen Lembert sutures, were passed through the peritoneal coat. As a precautionary measure the peritoneal cavity was irrigated with warm boiled water. The abdominal incision was then closed in the ordinary manner, the umbilicus being excised to facilitate approximation of the wound, and sufficient of the tendon was included in the sutures to insure a firm cicatrix. The wound was dressed with fifty per cent. iodoform gauze, over which were placed ordinary gauze and cotton which had been baked in an oven.

Dr. Goodell then continued: You might ask me why I did not do a Porro operation. The Porro operation is somewhat less successful than the Sänger, and as the ordinary Porro is nothing more than a supra-vaginal hysterectomy, it would not have removed the diseased tissue. If there had been any possibility of removing all of the cancer by hysterectomy, I should have performed this operation in preference to the Sänger operation. The disease is, however, so extensive, both the bladder and rectum being involved although not yet perforated, and the tissues are so matted together, that there would have been no possibility of accomplishing a radical cure.

In this case we employed chloroform as the anæsthetic, for when we have pressure on the respiratory organs and kidneys, by a tumor of any kind—and the pregnant womb is a tumor—I prefer to use chloroform. I use it altogether in the laparotomies at my private hospital. The apparatus which I employ is a very safe one, as the patient gets only a minim of chloroform at each compression of the bellows. Sometimes after the administration of ether, the kidneys becoming acutely congested refuse to work and I have had patients die from uræmic coma from suppression of the urine. Then again I have seen fatal œdema of the lungs follow its use in old people. Chloroform does not have such an injurious effect upon the kidneys or the lungs. Whenever albumin is found in the urine, no matter what the operation, I should always give chloroform in preference to ether. Also in the aged I should prefer the former anæsthetic.

I shall next pass my finger into the vagina and determine the condition of the cervix. The easiest plan would have been to open the cervix from above, but I feared that my finger would become contaminated by the cancerous juices, although the vagina had been thoroughly syringed with a 1 : 1000 corrosive sublimate solution. I find, however, that, owing to the curetting performed by my son, the finger readily enters the cervical canal so that there is a free avenue for the escape of the lochia.

I sincerely trust that this patient will recover. She deserves it, she has plenty of pluck, she is in as good a condition as a person with a cancer can be, and I think that the operation was performed under strict antisepsis. The only criticism that I have to make is in regard to the delivery of the child by the head. Delivery was accomplished more quickly in that way, but I might have been able to get the child out through a smaller opening had I turned and delivered by the feet. This, however, would have compelled the introduction of the whole hand deeply into the lower segment of the womb, where the breech lay, so I seized that portion of the body which was handiest.

To insure contraction of the womb, after the lecture was over a hypodermatic syringeful of fluid extract of ergot was injected into the thigh on its outer aspect.

NOTE.—*March 26th.* To-day, the thirteenth after the operation, this woman appears virtually out of danger. She eats and sleeps well, and has a full breast of milk. The infant is also thriving.

ELECTRICITY AS A THERAPEUTIC AGENT.[1]

BY M. ALLEN STARR, M.D., PH.D.,
PROFESSOR OF DISEASES OF THE MIND AND NERVOUS SYSTEM IN THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

IN the management of a business concern the results of taking account of stock and of balancing the books is rightly considered of supreme importance. Perhaps it might be of advantage to us as practitioners if the results of our work could be occasionally reckoned up in a similar manner, and a definite estimate made of the value of our methods. It is in pursuance of this idea that electricity as a therapeutic agent is brought before you for discussion to-night. Over a hundred years ago it was introduced into medical practice. Since that time it has met with varying degrees of favor. Twenty years since, under the impetus of German influence, its use in nervous affections was firmly established. Yet recent writings and text-books on the medical use of electricity show a disregard of recent advances in the knowledge of the physics of this agent. And it needs very little study to convince one that the modern view of electricity differs widely from the older views reproduced in medical literature. To follow them closely would lead one to consider electricity as an entity, possibly a fluid, which can be administered like a drug. The term "current" is partly responsible for this fallacy, it being difficult to deal with this term without imagining a flow of something in a definite direction. Yet just as the older term caloric is now discarded, and the old notion that "heat is the result of caloric being poured into a body" raises a smile, so similar fallacious notions regarding electricity should at present meet with disapproval.

The sooner it is realized that electricity, like heat and light, is merely a form of activity in matter, and the sooner the term "electrical currents" gives place to the more accurate phrase *state of electrification*, the sooner will the mystery surrounding this agent be cleared away.

When electricity is applied to the body a change is produced in the normal condition of the molecules making up the body, a new molecular condition is produced, but nothing is added to or subtracted from the body itself.

Between the two poles of the battery this molecular state is more intense than elsewhere, and under one pole it is somewhat different from that under the other. The intensity of the change is measured roughly in terms of the strength of its pull upon a balanced needle—but this should not lead to the adoption of such terms as a dosage of electricity, which, like the term current, is sure to mislead.

When electricity is thus regarded as a mode of energy capable of estimation, like other modes, in terms of work, it becomes evident that a valuation of the various forms under which this energy appears is possible.

In common usage these forms are static or frictional electricity, voltaic electricity or galvanism, and induced electricity or faradism. It should be distinctly understood that all these forms are really the same mode of energy displayed under varying conditions. An illustration may make this plain. Suppose that you have a dry sponge and a tumbler of water. If you throw the water over the sponge the greater part of it will run off, leaving only the surface of the sponge wet. You have applied a quantity at once, and your effect is short and soon over. Suppose, on the other hand, you let the water fall on the sponge drop by drop. It will soak in and wet it thoroughly but gradually, until in the end all the water will remain in the sponge, which is now soaking. The effect is slow but intense. Water and sponge are the same in both cases. The conditions vary under which they are brought together.

This illustration, which is not to be taken literally, may convey some notion of the difference between static and voltaic electricity. By the former sudden transient effects are produced very limited in intensity. By the latter, slow permanent effects are produced of much intensity.

I. STATIC ELECTRICITY.—It seems strange, when the history of the uses of electricity is reviewed, to find how much credence is still placed in the effects of frictional electricity. In the first place, the change of electrical state produced by it is limited exclusively to the surface of bodies charged. Take a metal ball insulated by a glass stand over which two hemispheres are fitted, and charge this with static electricity. If the hemispheres be now removed from the surface, they are found to carry all the electrical charge, and no change of electrical state has been produced in the metal ball beneath them. There is absolutely no proof that the human body acts in any way differently from the metal ball. Any effects obtained by static electricity must, therefore, be from surface stimulation; and, hence, wholly reflex and indirect in character. For this form of electricity does not penetrate the skin.

When the surface of a body is charged with static electricity, it discharges itself gradually into the air by diffusion, or directly into the ground if the body be not insulated. The human body cannot be permanently charged with electricity. The state of electrification on the surface of the body is communicated to the air about, which is thus put in a similar electrical state. But bodies in a like state

[1] Read before the New York Academy of Medicine, March 21, 1889.

of electrification repel one another. Hence the hair, when charged, is repelled from the body, and stands on end; air, when charged by diffusion, moves away from the body, and the air in motion is felt as a breeze; hence, when a person is charged with static electricity this breeze may be felt. There is no more virtue or curative property in an electrical breeze than in any ordinary draught of air. Hence, it is ludicrous to read of the beneficial effects ascribed to the electrical breeze.

If all effects of static electricity are reflex in their nature, due to irritation of the skin, then the agent differs in no respect from any mild form of counter-irritation—such as whipping with twigs, lomi lomi of the Sandwich Islanders, the needle douche of a Turkish bath—excepting, possibly, in the convenience of application. Stimulation of the circulation, contraction of muscles as from a blow, agreeable sensations, or sharp pain, may all be produced in such a reflex manner, if they are considered desirable. But no further distinctly curative effects can be admitted. And as we shall see later, the same effects can be secured by faradism.

I pass by the mental effects induced by any exaggerated idea of the mysterious power of electric sparks, as beneath our notice. The elements of mystery and of expectant attention doubtless play a part in the treatment of some functional nervous affections. It is an open question how far they may be legitimately employed. If static electricity relieves hysterical affections, it must be admitted that it is entirely by means of the mental effect produced.

II. VOLTAIC ELECTRICITY OR GALVANISM.—A frictional machine does all its work suddenly, in a fraction of a second. It is not capable of producing a constant electro-motive force. This can, however, be obtained from a galvanic battery; and very soon after the discovery by Volta, the use of static electricity was superseded in medicine by that of galvanism. The fact that a voltaic battery furnishes a definite amount of electro-motive force capable of doing a measurable amount of work and producing definite effects on the body suffices to explain its continued use. Yet, when we speak of definite effects from galvanism, I think there are few physicians to be found who will contend for a moment that there is any such certainty regarding the therapeutic effects on the body as there is regarding the use of drugs. Opium will quiet pain; aconite will depress the heart. Is there any statement which can be made with equal definiteness regarding electricity? I think not.

As far as the effects of galvanism are now known, they may be classified under three distinct heads, viz., catalytic, cataphoric, and electro-tonic effects.

a. Catalytic effects. The splitting up of a compound element into its constituent parts is one of the ways in which the work done by electricity is measured. The compound body is put into a state of electrification which makes the condition of its molecules so unstable that they fly apart, and as they burst asunder those which have taken on a state like that of one pole of the battery are repelled from it and appear at the opposite pole. A strong current passing through the body produces intense catalytic effects, disintegrating and destroying the tissues, and raising blisters under each pole, the one containing acid, and the other an alkaline fluid. Even with a weak current the taste produced in the mouth differs at the different poles, one being sour, the other salty. There is no doubt, then, that marked chemical changes may be produced by the galvanic current.

This power, then, may be used like that of any other destructive agent, to dissolve body tissues. In some cases—such as elimination of hairs from the face—it is convenient. How successful it may prove in the destruction of tumors—especially of the internal organs—it is hardly time to judge. In the resolution of strictures its use is strongly combated by eminent authority after thorough trial. In any case the difficulty of limiting its action, the serious nature of the wound which is left, the slow healing and deep scars which remain, combine to make it less certain, less definite, less satisfactory than ordinary surgical procedures—and, consequently, it is not endorsed by surgeons generally.

The use of mild, non-destructive currents has been urged by some, and it has been claimed that a catalytic effect of a moderate kind may aid nutrition. Nutritive processes are dependent on chemical and molecular changes. Is it possible to stimulate these by a constant galvanic current? Theory here is aside from the point. Experience must furnish facts. The only scientific observation which I have been able to find is furnished by Prof. James K. Thacher, of Yale, and it is certainly extremely valuable and interesting. In a case of bilateral paralysis of all the extremities, due to diphtheritic multiple neuritis, Dr. Thacher made a series of therapeutic experiments upon the arms—each arm being treated alone for a week at a time, and its relative gain under treatment being compared with that of the opposite untreated arm. The results were measured in degrees of strength of grip as determined by a dynamometer.

It was found that the arm to which a labile constant galvanic current was applied daily for ten minutes, gained in strength in a degree far greater than that of the untreated arm. So that the gain under galvanism could be exhibited as follows:

	Galvanized arm.	Untreated arm
1. Ten days' treatment to left arm	17° gain	12° gain.
2. Seven " " to right "	15° "	10° "
3. Seven " " to left "	7.4° "	0.9° "

The galvanized arm made almost double the progress of the other (1 : 1.72).

Under faradism there was no gain perceptible, and under massage there was a positive loss.[1]

I know of no other accurately measured, scientific test under proper conditions which demonstrates so perfectly the power of the constant galvanic current to promote nutrition. It would add greatly to our knowledge if similar observations were made. And it is undoubtedly the catalytic effect of the electricity which is responsible for the nutritive changes. These are certainly of the greatest importance in a large number of cases, especially in all forms of paralysis, where it is important to keep the muscles strong. It is undoubtedly through its catalytic action that galvanism produces effects in nervous diseases—if such effects are obtained. It is one object of this discussion to elicit the experience of those present as to these effects. I have never seen a case of organic disease of the brain or spinal cord which I could consider cured by the application of electricity. Such cases sometimes improve under treatment for a time, and then grow worse in spite of it. Others do not improve at all. Perhaps it is well to be more definite in statement.

In diseases of the brain, such as cerebral hemorrhage, sclerosis, abscess, tumor, or embolic softening, as well as in all forms of insanity, I consider electrical treatment useless. It cannot affect the pathological process which causes the symptoms. In diseases of the spinal cord it is usually recommended and often applied. Roughly, we may divide these diseases into (1) inflammatory destructive lesions of the gray matter, and (2) sclerotic processes. In the first class, of which disseminated myelitis and infantile paralysis may be taken as types, there may be an object in reducing congestion; but it is not certain that this can be accomplished for any length of time by electricity, as it can by counter-irritation or cupping. After the acute stage is over, spontaneous recovery will occur in greater or less degree in many cases. Is this aided by the application of electricity to the spinal cord? I have yet to be convinced that it is, though I admit that I still employ the agent in deference to the opinion of certain authorities. In the second class, of which locomotor ataxia is a type, it is theoretically difficult to assign any effect upon the sclerotic process of a change of molecular state. And, practically, it seems to me that few definite results can be affirmed regarding the effects of its application. Ataxia and spastic rigidity do not appear to be removed either temporarily or permanently, and its analgesic qualities are very often disappointing. In spinal affections, therefore, it seems to me that experience does not confirm the statements of some text-books and of those whose interests lie in the direction of its use.

This experience conforms to that of such a careful observer as Gowers,[1] who, in his recent text-book, states that electrical treatment fails in his experience to affect the progress of organic nervous diseases.

Another question of importance is, to what degree the electrical state is induced in deep-lying tissues such as the brain and spinal cord? The body is not homogeneous and the power of conduction of different tissues varies greatly. If two pipes lead out of a reservoir, one free, the other plugged with rubbish, the water will seek the easy outlet to the exclusion of the other. To rely upon the diagrams of the diffusion of electric currents in the body is to be misled. Muscle conducts easily, bone less so, least of all the nervous tissue, which is peculiarly insulated by its fluid surroundings. The result must be that but a small fraction of the current reaches the nervous organs in comparison with the amount applied. Just how much does reach them has never yet been accurately determined, and cannot be from the nature of the case in a state of health.

Recently the spinal cord and brain have been laid bare by surgeons. It would be profitable in future, in appropriate cases, to determine by accurate electrical measurements to what extent currents sent through the body affect these exposed parts of the central nervous system. There is no reason to suppose that such experiments would be dangerous.

In peripheral nerve lesions many of the objections urged against the use of electricity in affections of the central organs are obviated. It is possible to localize the application and to determine by the sensations and motions produced just what nerves

[1] The Medical News, April 18, 1885.

[1] The following quotations from Gowers are cited in support of the statement in the text:

"There is no evidence that the application of electricity to the spinal column has any influence on the process of recovery in acute myelitis. Its chief value is to maintain, as far as possible, the nutrition of any muscles of which the nerves have undergone degeneration."—Vol. i. p. 235.

No mention of electricity is made by Gowers in dealing with the treatment of chronic myelitis.—Pp. 245-6.

"Electricity has been strongly advocated and largely used in the treatment of infantile paralysis, and there is reason to believe that it is useful, although its influence has been much exaggerated. In no sense is it a curative agent, and there is no evidence that its application to the spine is capable of increasing the degree or accelerating the course of the recovery of the nerve elements. Nor is it easy to obtain evidence of its influence over the muscles. If the wasting is rapid, this progresses in spite of daily and sedulous applications. Nevertheless, its demonstrable effect on the muscles in causing their contraction must have an influence in the right direction upon their nutrition. This is of no avail if no recovery takes place in the spinal cord, but in most cases some recovery in the cord does occur."—P. 270.

"Electricity has little influence on the chief symptoms of tabes. The voltaic current is powerless over either the pains or the ataxy, whether it be applied to the spine or to the limbs."

After alluding to faradization of the skin in pain, and in incontinence of urine, Gowers adds:

"The central cause usually renders local treatment ineffective."—P. 326.

"Electricity is useless in spastic paraplegia."—P. 340.

"The most sedulous and skilful use of electricity—voltaic or faradic—fails, as a rule, to produce any effect on the course of progressive muscular atrophy."—P. 38.

are affected. It is not improbable that favorable nutritive effects are produced by the increased circulation and more rapid chemical changes induced by the agent. It would be interesting to ascertain definite time results in the treatment of these diseases. Is the duration of a lead palsy shortened by the application of a constant current? Is the course of a facial paralysis in any way affected by its use? I have been much disappointed by the lack of rapid results in the former. I have seen the latter go on to the most severe form, with a permanent paralysis, in spite of the most careful applications of electricity. Many cases of both diseases get well. Does electricity aid the cure?

In neuralgia the galvanic current is doubtless of service, the palliative effects of the positive pole being proven. The rule proposed by Dr. Gibney, of increasing the current until the patient has peripheral sensations in the area of distribution of the nerve treated, seems to me of great value, for unless such sensations are perceived it is unlikely that the nerve is really brought into a state of electrification. If the spinal cord is really excited by the current, why should not general peripheral sensations be produced? It is rarely that I have succeeded in causing them, and I do not think they are elicited in the usual method of application.

b. Cataphoric effects. The power of electricity to promote osmosis is well proven. A transfer of substances from the positive to the negative pole through intervening organic tissue can be made. This is termed a cataphoric action. It has been used of late in the production of local anæsthesia, and for the quieting of neuralgic pain; cocaine, morphia, and aconitia having been brought into direct contact with painful nerves in this manner. As a method of treating neuralgia this is of distinct service, as has lately been proven by Dr. Peterson before this Academy. Medicated electric baths, which might be arranged on this principle, cannot be at present commended, since the dosage of the drug thus employed is wholly uncertain.

c. Electrotonic effects. It has already been stated that the application of electricity produces a state of electrification in the molecules of the body. This state varies under the different poles of the battery, and each pole is supposed to produce an effect the exact reverse in kind from that under the other pole. These opposite states are known as anelectrotonus and katelectrotonus. It is not necessary for us to determine whether the state produced is due to a parallelism of molecular vibration, comparable to that occurring in polarized light, or whether it is a state induced in the dielectric, the impalpable ether surrounding the molecules. Suffice it to say that two electrotonic states exist, one at each pole, and that the tissues between the poles share in these states in the direct ratio of their nearness to the poles.

The sudden production of either state excites violent molecular movements in the tissues, and these become doubly violent if either state is suddenly replaced by its opposite.

Each tissue manifests its irritation in its own manner, the muscle by contraction, the motor nerve by sending a motor impulse to the muscle, the sensory nerve by transmitting a sensory impulse to the brain. Hence to excite tissues to functional activity sudden changes in their electrotonic state are produced by suddenly closing or opening or reversing the constant galvanic current. The last-named procedure, reversing the current, or using voltaic alternatives, is necessarily the most active excitant of all. No one can deny the beneficial effects produced by exciting the functional activity of the various organs, especially when, as in paralysis, the organs cannot be voluntarily set to work; for exercise aids nutrition, promotes the circulation, assists metabolism. It is probable that no other method equals this in these respects, massage being decidedly inferior. The electrotonic effect upon the vessel walls is also proven, for a decided dilatation of the smaller arteries can be seen after an application; and when this condition has passed off, if the part be immersed in warm water, the local redness becomes again manifest. This has been ascribed to the chemical changes set up by the catalytic action of the current, but the fact that it is more intense at the negative pole demonstrates that the result is due, in part at least, to the electrotonic state produced; and the fact that it is caused by a faradic current, which has no catalytic effect, confirms this statement. The effects of faradism are exactly the same as those of a very rapidly interrupted galvanic current. Faradism is indeed nothing more than a weak galvanic interrupted current reinforced by magnetic induction. The effects of faradism are, therefore, wholly electrotonic effects, never catalytic or cataphoric. Its convenience in being produced in a portable apparatus is its only advantage over voltaic alternatives. The difference of response to the faradic current from that of voltaic alternatives, in conditions known as the reaction of degeneration, is not to be ascribed to any difference in the nature of the current, but only to the fact that the degenerated muscle will not respond to changes of state so rapidly produced. Since muscular contractions are desired in the treatment of paralysis, it follows that faradism is useless unless the muscles act to it.

Admitting the great use of interrupted currents in exciting tissues to activity by producing changes of electrotonic state, can further claims be allowed? There is one which has already been alluded to in dealing with static electricity, namely the reflex effect of surface irritation. It is not unlikely that changes of circulation or of molecular state—very beneficial in character—may be excited in central organs by

such reflex irritation. It is evident, then, that the only possible effect admitted to occur from an application of static electricity can be produced equally well by interrupted currents.

To sum up the facts here presented we may say that

1. Static electricity offers nothing beyond an interrupted galvanic current, and fails to furnish those effects which are most desirable in the treatment of disease.

2. A constant galvanic current can produce chemical changes which aid nutrition, or destroy tissue according to the strength employed.

3. A constant galvanic current can transfer medicines into the body from without.

4. An interrupted galvanic current, or a faradic current, can excite various organs to functional activity, thereby aiding their nutrition.

5. It is questionable whether the pathological state causing organic diseases can be in any way influenced by electricity.

6. If functional diseases are benefited, it is in an uncertain manner; it being undecided whether it is by influencing the molecular condition, the chemical changes, the circulation, or the electrical state of the organ affected—or by the state of mental expectation induced. The agent is therefore used empirically, and the physiological indications for it are as yet uncertain. As a therapeutic agent its use is very limited and carefully balanced scientific observations are still needed to establish its proper sphere.

It has been the object of this paper rather to sum up certain facts as opposed to tentative theories than to state anything new. It is also the object to elicit expressions of opinion of the use of electricity in therapeutics—based upon the experience of those who have given it a careful trial. All reference to the use of electricity in diagnosis has been purposely omitted.

I cannot, however, close without stating that after the constant use of electrical treatment for the past six years in dispensary and in private practice, I have been disappointed in the results obtained. And I cannot ascribe this lack of result to any defect in the applications, for they have been made with care, with the best of apparatus, and with exact galvanometric measurements, according to the methods described by such authorities as Erb, De Watteville, Benedickt and Beard. My experience coincides with that of Gowers that the therapeutic effects of electrical applications have been much exaggerated and are really very limited and quite uncertain.

INTRAMUSCULAR INJECTIONS OF MERCURY IN SYPHILIS.[1]

By HENRY BUCKMASTER DEALE. A.M., M.D.,
of Washington, D. C.

The subject of hypodermatic or intramuscular medication in syphilis has, of late, claimed such an amount of attention that I thought possibly a brief history of a few cases, which it was my good fortune to have in charge, might prove of some little interest to this Society.

After a tolerably thorough investigation of the bibliography of the subject, I find that very few of the profession in America have written on this method of treatment; indeed, only three names of our own countrymen were found; France and Germany being the principal localities for its discussion. A method introduced as long ago as 1864, by Scarenzio, in Italy, has until quite recently lain dormant, and is now a subject occupying the minds of many leading syphilographers of the continent.

The majority, or, indeed, nearly all of those whose writings I sought, use either calomel in glycerine or the perchloride of mercury in distilled water, though many other preparations of mercury are recommended, all claiming various advantages for their special preparations.

In the few cases I present, the bichloride of mercury only was used, injected deep into the gluteal muscles, with certainly most satisfactory results, so far as my observation of the cases was carried, though scarcely sufficient time has elapsed to prove anything positive.

Without doubt, at first thought, the mild chloride would seem the preparation possessing superior advantages,—it being injected in the insoluble state, is slowly changed by the chlorides of the blood to the soluble double chloride, thus being absorbed more slowly, and at the same time eliminated very much more gradually, thereby keeping the system under its influence longer, and necessitating fewer injections; but, strange as it may seem, the experiments with calomel have had a much more direful history as regards the formation of abscesses, notwithstanding it is supposed to be the less irritating preparation.

The only objections to this method of treatment urged by its many opponents, are the danger of formation of abscesses, and the pain at time of injection and for a short time subsequent; now, if these be proven unfounded, certainly none but would acknowledge this method as superior in every respect to the old forms of treatment, which have always possessed many serious drawbacks. As given through the alimentary canal, there is a constant tendency at least to a derangement of this tract, with greater

[1] Read before the Clinico-Pathological Society, of Washington, D. C., Nov. 6, 1888.

probability of salivation; the inunction method possesses the objection of uncleanliness with others, etc.

Among the claims to superiority of the intramuscular injections, may be enumerated: the exactness of the amount of mercury absorbed by the system; the avoidance of gastric and intestinal derangements; the slightest probability of salivation; and the absolute knowledge possessed by the physician that his medication is followed, a fact of which he is not always possessed.

In answer to the first, and really only rational objection urged, namely, the danger of abscess, the results of many skilful experiments, as well as my own slight experience, demonstrate that this danger may be reduced to a minimum, or, indeed, *nil*, if due care and caution are exercised by the practitioner.

J. A. Bloxam, of Charing Cross Hospital, England, gave 1924 injections of the bichloride of mercury, with only one abscess, and this he was convinced was due to the injection not having been inserted sufficiently deep. Lewin is reported to have given the incredible number of 300,000 injections, with only 20 abscesses; Parkert 5000 injections, with no abscesses; Segmund 631 injections, with 5 abscesses; Smet 900 injections, with none; and I myself have given about 230 injections, with not a single abscess. All the above statistics are where corrosive sublimate is used in varying doses.

The result is by no means so favorable as regards abscesses when calomel is the preparation injected. Smirnoff gave 1523 injections of calomel in varying proportions from ⅜ to 1½ grains, with 72 abscesses, or about four per cent., and as far as I was able to discover, I found no one who recorded more satisfactory results with calomel than Smirnoff.

Dr. J. C. Wilson, of Philadelphia, in a very interesting article in The Medical News, reports several cases with most satisfactory results when calomel was used; he much prefers this preparation, on account of its "prolonged and relatively mild influence." Women, it appears, are more subject to abscesses from injection than men, due, it is supposed, to the greater amount of cellular tissue in the locality the injections are given, and the solution not being thrown into the muscle,—as all the patients under my care, in which this treatment was followed, were males, I, personally, have had no experience in this regard.

In reference to the pain inflicted, all observers state that it is of rare occurrence that any objection is urged on this accouut, though that there is slight pain, there is no doubt; in only one instance was this objection made by those under my care. It is recommended that a few drops of cocaine solution be added to the mercury solution, but I think this is fraught with some danger.

The following is a brief synopsis of three or four of those cases under my supervision:

Case I.—J. R., white, male, twenty-eight years, laborer, Irish, had primary sore about six months previous, applied for treatment suffering from pronounced secondary symptoms, viz,, alopecia, sore throat, periosteal pains, etc., the cervical, inguinal, and epitrochlear glands indurated.

He was first given green iodide of mercury one-third of a grain t. i. d., which so soon deranged his stomach, with no apparent abatement of symptoms, that it was determined to try intramuscular injections of the bichloride of mercury; one-sixteenth of a grain was injected daily for four weeks; the pain in the tibia, which had been so severe as to keep him awake at night, gradually disappeared, and all other symptoms rapidly improved. He returned to his work, reporting from time to time for six months, with no return of any symptom.

Case II.—J. C., white, male, thirty-three years, laborer, American, had primary sore quite ten years before, and always since that time had some pronounced symptom, though having been under medical care off and on during all these years. He came to the hospital especially for treatment of his eyes—he was suffering from cyclitis and choriditis, being only able to distinguish light from darkness. His alimentary tract was in such a condition, from the excessive use of mercury, that not the lightest diet could be retained, and he had severe diarrhœa. His body and limbs were absolutely covered with a coppery eruption, his hair and beard thin and in patches, suffering at times with most excruciating pains in limbs. Twenty-five hypodermatic injections of $\frac{1}{16}$ Hg_2Cl_2 were given within a month and a half, with bathing the eyes in hot water, and atropine solution (4 grs. to ℥j) in eye morning and evening. His eyesight gradually improved until he was able quite readily to walk about house and grounds, also to read large print. The eruption to a great extent faded, though not entirely; his general health and strength were much better than for years. At one time there being some slight tenderness of gums, the injections were omitted for five days, after which time they were given daily until his discharge.

Although asked to report from time to time, nothing was heard of him except that he had fallen into the hands of a physician who was continuing the same form of treatment, but with what further results I cannot state.

Case III.—J. A., white, male, forty-one years, laborer, American, primary sore one year before, suffering from a most severe form of iritis, body covered with eruption, inguinal glands indurated.

Twelve injections of $\frac{1}{16}$ gr were given him, with a rapid disappearance of the iritis, and fading of the eruption.

Case IV.—D. R., white, male, thirty-nine years, bookkeeper, American, had primary sore some years before, exact time not known. He had extreme sore throat, with extensive ulceration of soft palate, intense pain in limbs, thereby incapacitating him for work.

Twenty-five injections were given daily, after which ten injections were given at the rate of one every other day, finally twelve injections at the rate of one twice a week—making a total of forty-seven injections with an entire disappearance of all symptoms; this case is still under observation, it now being five months since any treatment was given.

Several other cases might be cited, but I have selected these as the most pronounced in symptoms, though the results in all were satisfactory.

As before stated, I have given in all 230 injections with no evil consequences and with most satisfactory results; now I am aware that such a limited experience does not permit me to urge that abscesses are inexcusable and due to lack of care on the part of the practitioner, but without doubt it is permissible to say that if proper care is exercised such a calamity would be exceedingly rare. The following are the precautionary methods which guided me:

1. Wash the part to be injected with a warm carbolized solution.

2. Wash the syringe and needle with warm carbolized solution before and after each injection.

3. Have the chill taken off the mercurial solution by placing the bottle in hot water, while making the other preparations.

4. Inject with a sharp, fine needle deep into the muscles of the buttocks.

5. Alternate the injection from day to day from right to left side.

6. After removing the needle use friction over the point of injection for a few seconds.

Much trouble is caused by the needle used, the action of the bichloride on the metal corroding it and making it brittle; but I have found that if the needle were well greased with vaseline before and after each injection, this could be obviated, also the small wire inserted through the needle should be anointed, with these precautions I have used the same needle for five months.

The solution used was as follows:

℞.—Hydrarg. bichlor. . . . . gr. iij.
Sodii chlor. . . . . ʒss.
Aquæ destil. . . . . ʒx.—M.
Inject ♏x to ♏xx.

It is advised to give some simple tonic during the time the treatment is being continued.

These results of many most skilful and cautious experimenters, with my own slight experience, have been presented, not so much to laud the intramuscular injections, or any special preparation of mercury in the injection, as I believe with due care any of the forms of mercury suggested could be used without danger, being only guided by the urgency of the symptons; but rather to prove that a method dismissed by most authors with a very few unfavorable words, and discountenanced by many practitioners on account of danger of abscesses, does not possess by any means the dangers or drawbacks attributed to it; also to urge its trial by those who have not yet proven or disproven these assertions.

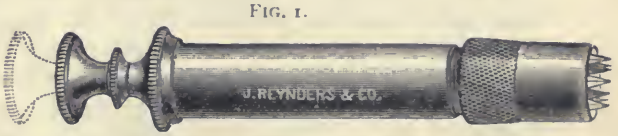
Washington, D C.

THE TREATMENT OF ACUTE INFLAMMATION OF THE MIDDLE EAR.[1]

By GORHAM BACON, M.D.,
of New York.

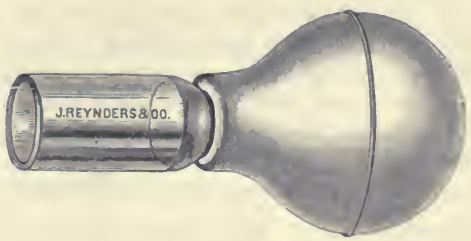
It is not my intention in this paper to describe the different methods of treatment that have been recommended from time to time, in acute inflammation of the middle ear, but simply to refer to a plan of treatment which, in my hands, has proved most satisfactory in its results, and to call attention to the use of the artificial leech, which I described in the *N. Y. Medical Journal* of Jan. 7, 1888. I feel justified in again referring to this instrument, as a number of others, who have since used it, have arrived at similar conclusions as myself.

Fig. 1.



The artificial leech consists of a scarificator, composed of seven lance-shaped needles, which are concealed. The depth of the punctures can be

Fig. 2.



regulated by screwing or unscrewing the end or cap of the scarificator. When this has been determined, the spring is pulled back, the instrument is applied to the parts and the tissues scarified.

[1] Read by title before the New York State Medical Society, Feb. 5, 1889.

A cupping-glass made adaptable to the parts about the ear, is then immersed in hot water for a few moments in order to promote the bleeding as much as possible and applied close to the tragus, below the lobule, or over the mastoid process, according to the seat of the inflammation. The glass itself holds three drachms. The cup when applied is held in position by the patient.

The reasons that I gave a year ago for discarding the leech and substituting the scarificator and cupping-glass were the following:

1. The leech is particularly disagreeable to many patients, especially children.

2. It is frequently very difficult to arrest the bleeding following a leech-bite.

3. A leech-bite occasionally gives rise to erysipelatous inflammation and ulceration and not infrequently produces a circumscribed abscess even in apparently healthy individuals.

4. Leeches are not always to be had, especially in the country, and are very frequently a troublesome remedy besides being expensive.

With the artificial leech, on the other hand, the quantity of blood abstracted can be entirely regulated and its application is more agreeable to the patient, besides being an instrument that is always at hand.

I use the artificial leech not only in dispensary practice but also at my office, so that I am able to note the good effects usually following the local abstraction of blood, while I am certain of having the leech applied at the proper point about the ear, which is a most important consideration.

It is in the first or hyperæmic stage, either of catarrhal or purulent inflammation of the middle ear, where the tissues are deeply congested, that the local abstraction of blood is followed by such favorable results as are shown by relief from the pain and tension in the ear. The inflammatory process will frequently be cut short at once by the early application of the leech, and I believe that in all cases the further progress of the disease will be greatly modified.

Not only is the local abstraction of blood by means of the artificial leech followed by most beneficial results in the early stage of acute inflammation of the middle ear, but also in acute inflammation of the external auditory meatus and mastoid cells.

The following are a few among a great number of cases in which I have used the artificial leech.

CASE I.—Wm. C., æt. eighteen years, was seen by me Jan. 11, 1887, on account of an ear-ache in his right ear, which commenced January 4th. The discharge appeared January 9th, but the pain continued. He had a similar attack a year ago. Watch, right ear, 0″; left ear, normal. Bone-conduction better than the aërial for the right ear. Right membrana tympani swollen, inflamed; perforation in the post inferior quadrant; some scanty purulent discharge in the middle ear, which was forced out by inflation. The artificial leech was applied and the pain was somewhat relieved. He was also given drops of zinc sulph., grs. iv–℥j, to use twice a day.

Jan. 15. The pain in the ear disappeared two hours after the cupping at the last visit and has not troubled him since. The canal contains pus in greater quantity. There is a slight enlargement of the glands over the mastoid. To continue using the same drops.

CASE II.—J. O'B. consulted me Feb. 8, 1887, on account of pain in the left ear, which he had had for two weeks. It is especially severe at night and there is some pain on swallowing.

Examination.—Right auditory canal contains cerumen. Left membrana tympani somewhat congested and very much retracted. Watch, left ear $\frac{15''}{48.}$

Politzer inflation somewhat painful. The artificial leech was applied just below the lobule and over the mastoid process. There was immediate relief from the pain. The patient was not seen again.

CASE III.—Thomas W., aged nineteen, a carpenter by occupation, said that for the last three nights he has had severe pain in the left ear. There is also a dull throbbing noise. Watch, right ear 4″; left ear, contact. The bone-conduction is slightly better than the aërial for both ears. Left auditory canal congested; there is also slight inflammation of the membrana tympani but no perforation.

The ear was inflated after Politzer's method; some slight cheesy matter was syringed out and the artificial leech applied.

Feb. 18. He has had no pain since. There is a slight discharge in the canal. Politzer inflation. To use drops of zinc. sulph. grs. iv–℥j. Watch: right ear, 8″; left ear, 5″.

25th. Much improved. To continue the same treatment.

CASE IV.—Max S., aged forty-three, a porter, complained March 4, 1887, of a sore throat and cold, which he had had nine days ago and which extended to the left ear. He says he has had a blister over the mastoid. The pain has been very severe every night but it is somewhat less to-day since the ear has been discharging.

Examination.—Right membrana tympani somewhat retracted and hazy; cone of light very small. Left auditory meatus inflamed and contains pus.

The artificial leech was applied just in front of the tragus and he was given drops of zinc. sulph. grs. iv–℥j.

The patient returned March 11, and said that he had no pain on the night of March 4, but that it has been present more or less since then. The ear was again cupped. He was not seen again.

CASE V.—Rebecca K., aged thirty-eight years, came to the Infirmary March 29, 1887, and said that she first had pain in the right ear two weeks ago. The right membrana tympani was found very much congested, as well as the inner end of the auditory canal; the left membrana tympani retracted and showing evidences of catarrhal changes. The arti-

ficial leech was used and she was given drops of atropiæ sulph. grs. iv–℥j.

She returned April 1, and said that she had not had much ear-ache but considerable pain in the right side of the head. The congestion of the drumhead and canal was much less.

CASE VI.—Mary G., aged twenty-five, a domestic, came to the Infirmary April 5, 1887. She says that last week she had a severe head-cold. Sunday night, three days ago, she had pain in the right ear, which has been present more or less since then, but has been somewhat easier last night and to-day. Watch: right ear, 0″; left ear, 15″. The right membrana tympani very angry-looking and congested and slightly bulging. The inner end of the auditory canal congested and losing its dermal lining. The membrana tympani was punctured and a few drops of pus evacuated. The artificial leech was then applied just in front of the tragus.

April 8. She returned to-day and said that the pain had been much less ever since she was here. The drumhead shows less congestion and there is some pus in the canal, which was syringed out. Watch, right ear, 1″. The ear was inflated by Politzer's method and she was given drops of zinc. sulph. grs. ij–℥j.

CASE VII.—Anna K., aged fifty-three years, was seen April 19, 1887. She says she never had any previous ear disease. She has had a cold in her head and chest most all winter. She has lately had a fresh cold, and three days ago the right ear pained her severely. This continued yesterday but is not as bad to-day, as she only has an occasional stinging pain. She complains of a buzzing noise in the ear and there is some tenderness behind the auricle and below the mastoid. Watch: right ear, 1″; left ear, 6″. The right membrana tympani very much congested as well as the entire auditory canal, which is swollen as well.

The artificial leech applied to the ante-auricular region and also over the apex of the mastoid process caused the pain to disappear at once. The tinnitus was also much less. She was given drops of atropiæ sulph. grs. iv–℥j. She was not seen again.

CASE VIII.—John Van T., aged thirty-three years, railroad employee, May 27, 1887. He has had an ear-ache on the left side steadily for a week and on examination, the bottom of the left auditory canal contains some inspissated pus, which was removed with the syringe. The drumhead was then found perforated and congested, as well as the inner end of the auditory canal.

The leech was applied in front of the tragus and just below the pinna. The pain entirely disappeared. The patient was not seen again.

CASE IX.—Caroline A., aged nine years, was seen at the Infirmary, April 26, 1887. Two months ago, she says, she first had a discharge from the left ear which lasted for two days. She had no further trouble then till four days ago, when she had severe pain at night. This has continued day and night ever since and there has been no discharge.

Right membrana tympani dull, thickened and retracted, with almost no cone of light. Left membrana tympani macerated, congested, with the dermal layer peeling off, as well as from the inner end of the auditory canal, which is likewise congested.

An artificial leech applied, relieved the pain at once. The ear was inflated by Politzer's method and she was ordered to douche the ear with warm water at home.

April 29. The ear has been better since she was here, but this morning she experienced some pain. The leech was again applied. The patient was not seen again after this.

CASE X.—A physician, aged thirty years, came to see me January 3, 1889, on account of a dull pain and slight deafness in the left ear, which he first noticed the previous night. There was also some tinnitus and an examination of the ear showed some congestion of the left membrana tympani, especially along the handle of the malleus.

The artificial leech was used, giving immediate relief to the pain. An astringent spray was used in the posterior nares and drops of a 4 per cent. solution of cocaine instilled warm into the ear. He was also told to take small doses of aconite. He returned the following day and an examination of the ear showed absence of all inflammation. The pain and noise in the ear had entirely disappeared.

A NEW METHOD OF MAKING ANAËROBIC CULTURES.

BY JOHN A. JEFFRIES, M.D.,
OF BOSTON.

ALL who have had occasion to grow bacteria without oxygen must have been struck by the difficulty of the various methods described, the time required, the expense, and the doubt in each case if oxygen has really been excluded.

The earlier methods of covering plate cultures with a sheet of mica, or filling up test-tubes with sterile gelatine, are insecure and do not offer any evidence if oxygen has obtained access to the culture, while the last has the great objection of making the culture inaccessible.

The more recent methods, which depend upon driving out the oxygen with carbonic dioxide or hydrogen, are very troublesome in practice, and, as an atmosphere is left, often leave one in doubt if oxygen is really absent, to say nothing of the presence of the carbonic dioxide. The latest method depending on the absorption of oxygen by pyrogallic acid in caustic potash solution is efficient in removing the oxygen; there is always, however, danger of leakage around the cork.

None of the methods give any evidence of gas being given off by the culture.

Desiring to determine the ability to grow without air, as well as to gauge the fermentative powers of a large number of species of bacteria, I was forced to search for an easier and more accurate method, and have adopted the very simple one of inversion over mercury.

It is only necessary to inoculate the gelatine culture as usual, fill the tube up with mercury, cover with the thumb and invert, as done in preparing tubes for gas analysis, in a small crucible containing mercury. The tubes can then be stood in a rack and watched from day to day as easily as if in the open air.

This method is certainly simple, takes less than a minute's time and is inexpensive; besides the advantages in execution over the ordinary methods, it has the further advantage of giving prompt proof of the presence of air, such rising to the surface of the mercury on inversion, and retaining any gases that may be evolved by the culture.

As the time of manipulation is very short, the danger of contamination is slight. Should any foreign germ get in, it must form a colony and become visible.

It is almost needless to say that sugars and starches may be added to the gelatine, and that the mercury should be sterilized in the steamer before use. If the mercury is dirty, it can be filtered, cleansed with twenty per cent. nitric acid, or, what is much simpler, wiped with absorbent cotton.

The fear which I at first entertained that the mercury would kill the bacteria has proved unfounded, the plants growing on the surface of the gelatine in direct contact with the mercury.

It is my habit in cases where no growth takes place to pour out the mercury, put in a cotton plug and stand the tube back in the rack. After the lapse of a few days, growth usually takes place, thus proving that the plants have not died from poisoning or suffocation.

MEDICAL PROGRESS.

A New Procedure for Destroying Tattoo-marks.—It is well known how difficult it is to destroy tattoo-marks, which are at times so annoying to the unfortunate ones who have been foolish enough in a thoughtless moment to allow their bodies to be covered with designs often more or less obscene. Dr. Variot has just indicated a new procedure, after a number of experiments which he has carried out at the Central Infirmary of the Paris prisons. He pours at first upon the portions of the tattooed skin a concentrated solution of tannin; then, with the aid of a bunch of needles like those employed by the tattooers, he makes close punctures over the whole surface of the discolored skin. He then passes a stick of nitrate of silver with considerable pressure and friction over the whole surface upon which he has operated and pricked in the tannin. He allows the concentrated solution of the silver salt to act for a few instants upon the epidermis and the derma until the pricked points become of a dark or black color. He then wipes off the skin, and the surface is found to have become black from the formation of a tannate of silver which is produced in the superficial layers of the skin.

In the first two days which succeed the cauterization there is a slight inflammatory reaction, with a variable amount of pain. In the two following days all parts which have had the tannin pricked in and the nitrate of silver subsequently applied take on a deep black tint, forming a sort of crust, or eschar, which is thin but quite adherent to the deeper parts. On the third or fourth day after the operation the crusts are wholly painless. If, however, the tattoo has been extensive, the movements of the parts may become painful. At times a little suppuration takes place beneath the crust, but there is never a great degree of inflammatory reaction. . . . In from twelve to eighteen days the crust, or superficial eschar, becomes detached spontaneously, the derma and epidermis have become repaired beneath it, and there is seen in place of the tattoo which has fallen with the crust a superficial red cicatrix which becomes progressively decolorized, and two months after the operation is but very little noticeable.

Dr. Variot has employed without success fly-blisters; the red-hot iron, which may leave disfiguring cicatrices; tattooing with white substances, such as powders of enamel, pricking in milk, phenic acid, and tincture of cantharides. He has used tannin alone, acetic acid, the acid oxalate of potassium, and the ten per cent. solution of nitrate of silver—all to no purpose. The author thinks that his procedure could be employed with advantage in natural pigmentary spots and in congenital nævi more or less extensive and more or less deforming. Apropos of Dr. Variot's communication to the Society of Biology, Dr. Dupuy said that in the islands of the Indian Archipelago they cause tattoo-marks in Europeans to disappear by practising a new tattooing with the juice of the *Carica papaya*. The operation leaves no cicatrix, and takes away red tattoo-marks as well as the blue ones.—*Journal of Cutaneous and Genito-Urinary Diseases*, March, 1889.

Acute Gonorrhœa treated successfully by a New Method.—Dr. John M'Caw, of Belfast, reported at a meeting of the Ulster Medical Society held January 23, 1889, a case of gonorrhœa contracted four days previously, treated by the introduction into the urethra of medicated bougies; the medicament consisted of sulphate of thallin of five per cent. strength.

Before introducing the bougie he made the patient micturate, in order to clear the urethra of discharge, and then passed the bougie up to the ring, and directed him to hold the meatus quite close, so that none of the application could flow out as it melted. He kept him lying on his back for twenty minutes, at the end of which time he withdrew the spring and closed the meatus with cotton-wool. During the time the bougie was in the urethra he complained of smarting pain, but after he withdrew the spring the pain ceased entirely, and he expressed himself as feeling comfortable. He introduced one every evening after this, and on the third day he called to say he was quite cured, having no discharge of any kind, and no pain on passing water. The day following happened to be his busiest day in the week, as he had to work to twelve o'clock at night, and be on his feet the greater part of that time. In consequence of this he could not use his bougie that day at all, and on the next morning there was a slight return of the former symptoms; but he began anew his treatment, and after using two more bougies, was again perfectly cured. He

has remained so since, although he has undergone the heavy day of the week which caused him to relapse before, and this time with impunity. No bad after-effects of any kind resulted from the treatment, and his patient was very grateful, as well as very much surprised and delighted, for he had been looking forward to a two months' course of copaiba-drinking as in a previous attack with anything but pleasant recollections.—*Dublin Journal of Medical Science*, March, 1889.

Tannin Treatment of Phthisis.—Dr. E. Houzé, of the Hospital St. Jean, Brussels, after having tried the tannin treatment on all his phthisical patients for the last year and eight months, states as the result of his observations that it gives excellent results in all stages of the disease, and especially in the condition where cavities exist. Indeed, he has no hesitation in declaring that of all the different kinds of treatment for phthisis which he has tried this has given by far the most encouraging results. The dose he employs ordinarily is fifteen grains, which quantity is taken three times a day. It is, as a rule, well borne; where this is not so, it is ordered to be taken with meals. After the first few days the expectoration and the sweats diminish, the cough decreases, and in many cases the appetite undergoes a marked improvement. The majority of the patients suffered from some slight degree of constipation, though in some this feature was sufficiently marked to require treatment; while others, again, suffered from diarrhœa. The character of the expectoration changed for the better, the sputa becoming white and frothy instead of green and firm. In some cases the diminution of the expectoration was followed by increased dryness of the cough, so that the patients complained that it fatigued them more; this was easily remedied by prescribing a few spoonfuls of syrup of codeia. The physical signs underwent a remarkable change for the better, at least those depending on auscultation, moist râles giving place to dry rhonchi, and large gurgling râles decreasing progressively until they gave place to mere blowing respiration. These changes were evidently due to the drying up of the cavities, in consequence of which the hectic present in many of the cases vanished, the patients increasing considerably in weight and gaining strength in a remarkable manner. The percussion signs were not found to undergo so marked a change as those dependent on auscultation, but even here some improvement could be detected. No bacteriological observations were made.—*Lancet*, March 9, 1889.

Treatment of Ozœna.—*General treatment* consists in the use of tonics, cod-liver oil, and iodine preparations.

Local treatment must be antiseptic, hence the patient should make use of nasal irrigation, using for this purpose from two to four pints of a sulphurous water, or a salt or chlorinated solution (using one tablespoonful of rock salt to two pints of water) or a solution of potassium.

A second irrigation should be made with an antiseptic solution of chloral, of creolin, of salicylate of soda or carbolic acid, as, for example:

℞.—Creolin	. . . . .	1 part.
Alcohol (pure)	. . .	120 parts—M.

A solution to be made by taking one teaspoonful of this mixture to two pints of warm water.

Or,

℞.—Carbolic acid	. . . .	20 parts.
Pure glycerin	. . . .	100 "
Alcohol (90 per cent.)	. .	50 "
Water	. . . . .	350 " —M.

Sig.—A tablespoonful to two pints of warm water.

After the lapse of several weeks, treatment is completed by the application of astringent powders such as tannin, which has been rendered antiseptic with chloral or carbolic acid. The following formula is recommended by Dr. Moure:

℞.—Carbolic acid	. . . .	40 parts.
Resorcin (crystallized)	. .	6 "
Glycerin (pure)	. . .	100 "
Water	. . . . .	1000 "
Antiseptic vinegar	. . .	1 part.—M.

or,

℞.—Camphor	. . . .	8 parts.
Tincture of iodine	. . .	10 "
Tar	. . . . .	12 "
Alcohol (40 per cent.)	. .	100 "
Water	. . . . .	250 " —M.

Heat over an alcohol lamp and inhale the steam.

The applications of the powder as well as the steam inhalations are to be repeated, the latter mornings and evenings, for months and even for years.—*Revue gén. de Thérapeutique*, February 14, 1889.

Gangrene of the Colon: Successful Resection.—In the report of the meeting of the Edinburgh Medico-Chirurgical Society, held December 5, 1888, reference was made to a case of cure, by resection of the intestine, of a fecal fistula, which was the result of extensive gangrene of the transverse colon. The case, which was under the care of Mr. Cotterill, Assistant-Surgeon to the Edinburgh Royal Infirmary, has since been published. The patient was a very stout woman, eighteen stone in weight, and thirty-eight years of age. She had been subject to umbilical hernia for seven years. When seen by Mr. Cotterill she was seven months pregnant. The rupture was a bright red and angry-looking prominence about fourteen inches in diameter. The patient vomited coffee-colored fluid mixed with blood. The sac was opened, and was found to contain a large coil of gangrenous transverse colon, much sloughy omentum, and free from feculent matter. The gangrene appeared to be due, not to strangulation, but to pressure of the structures in the sac, between the pregnant uterus below and a firm binder which had been worn above. Fifteen inches of colon were cut away, and the ends of the gut were stitched to the edges of the skin-wound. The patient gave birth to a child three days after the operation.

For three months after convalescence the patient was troubled with prolapse of the intestine, with discharge of feces whenever she walked much about. She again put herself under Mr. Cotterill's care. He succeeded in keeping patent both sides of the intestinal tract, and then performed resection. The two cut ends of intestine were freed from adhesions, the upper being first ligatured to avoid the escape of feces. Traction was then made on the two ends until normal gut, covered with peritoneum, protruded sufficiently for resection. Instead of using a clamp, the operator passed a piece of thin India-

rubber tubing through a small hole in the mesentery and round the gut, fixing it there with a pair of catch forceps. Four inches of the upper segment of the colon and three of the lower were then cut away, with portions of mesentery. As the lower segment had been five months in abeyance, it was very narrow and hard to join to the upper piece. By careful introduction of over a hundred stitches, the ends were brought satisfactorily together. Fine curved needles were used, round, not flattened, and threaded with the finest Chinese twisted silk, and the Czerny-Lembert suture was employed. The cut edges of the mesentery were sutured together, and the gut was returned into the abdomen. The large umbilical opening was brought together by deep silk stitches, and a pad and binder were applied. The operation took three hours. On the third day feces passed. The patient made a good recovery. No less than twenty-two inches of large intestine were removed in the course of the two operations.—*British Med. Journal*, March 2, 1889.

The Duration of the Life of Pathogenic Microbes in Water.—Drs. I. Straus and A. Dubarry, in an exhaustive paper upon this subject, conclude with the following *résumé*:

Bacillus anthracis (without spores) was found alive in water at the end of 16, 24, 28, 65, and 131 days. Dr. Meade Bolton found it dead at the end of 6 days; while Dr. Wolffhügel found it still alive at the end of 15 days.

Bacillus of typhoid fever was found alive after 30, 35, 43, 69, and 81 days. Dr. Meade Bolton found it alive after three weeks to one month; while the researches of Wolffhügel and Riedel found it alive after 21, 27, and 28 days.

Spirillum of Asiatic cholera found alive after 16, 26, 30, and 39 days. Drs. Wolffhügel and Riedel found it alive in sterilized river water, after seven months.

Bacillus of tuberculosis found alive after 24, 25, 27, 30, 75, and 115 days; its virulence, however, seemed to be weakened from its long stay in the water. Drs. Chantemesse and Widal have found it alive in sterilized river water at the end of 50 and 70 days.

Bacillus of glanders found alive after 19, 28, 50, and 57 days.

Streptococcus pyogenes found alive after 8, 10, and 15 days.

Staphylococcus pyogenes aureus found alive after 9, 13, 15, and 21 days. Dr. Meade Bolton has found it alive after 20 and 39 days.

Bacillus of green pus found alive after 20 and 73 days.

Pneumo-bacteria of Friedländer found alive after 4, 7, and 8 days.

Micrococcus tetragenus found alive after 19 days (according to Dr. Meade Bolton, after 4 to 6 days).

Microbe of chicken cholera found alive after 2, 3, and 8 days.

Bacillus of rouget found alive after 17 and 34 days.

Bacillus of septicæmia of the mouse found alive after 19 and 20 days.

Thus, contrary to the opinion generally held, and above all defended by Dr. Meade Bolton, the foregoing would prove that there is no radical distinction to be made between the pathogenic microbes and the common microbes of water, as to their faculty of multiplying and living in water. A large number of pathogenic microbes possess this faculty, although to a less degree than the ordinary water microbes.

This is a conclusion, the correctness of which has already been admitted by Drs. Wolffhügel and Riedel.

As to the bacillus anthrax, the authors have shown that, placed in distilled water, it will give birth to spores.

This is then, no doubt, the reason why the bacilli (which produce spores) show a greater vitality in water than the micrococci. Furthermore, the chemical composition of water has no appreciable influence over the duration of the life of the pathogenic microbes living therein; they live equally as long in absolutely pure distilled water, or in water charged with organic and inorganic material.—*Archives de Méd. Expérimentale*, January, 1889.

Anæsthetic Effects of Carbonic Acid Spray.—Professor Brown-Séquard has on various occasions drawn attention to the anæsthetic properties of carbonic acid employed in inhalations or in the form of spray on the larynx. He stated at a recent meeting of the Société de Biologie that he lately had recourse to this procedure in a case of lumbago, and obtained complete success. The analgesia produced by the carbonic acid is sufficiently durable; he had seen it persist during thirty-six hours.—*Lancet*, March 2, 1889.

Colchicin in Diseases of the Eye.—Dr. Darier at the last meeting of the Parisian Society of Ophthalmology recommended colchicin in eye affections. The best results were obtained in marginal ulcers of the cornea of gouty origin, in certain cases of iritis, scleritis, and anterior sclero-choroiditis; also in certain forms of serous iritis doses of $\frac{1}{32}$ to $\frac{1}{16}$ of a grain were found of great service. In chronic and severe cases in which salicylic acid was powerless, colchicin generally effected a cure. The author administers colchicin in pill form, each pill containing $\frac{1}{64}$ grain of the drug of which from 1 to 2 or 4 or even 6 pills can be taken daily. Care must be taken to instruct patients to reduce the dose as soon as intestinal derangements manifest themselves. Treatment must be continued until a complete cure has been effected, otherwise relapses will occur. Some patients have taken as many as 200 pills, without complaining of unfavorable symptoms.—*Wiener med. Wochenschrift*, February 24, 1889.

Acupuncture in Enlargement of the Spleen.—At the Congress of the Italian Society of Medicine, held at Rome some months ago, Dr. Feletti related two cases of chronic malarial enlargement of the spleen which he had treated successfully by acupuncture. He used steel needles, such as are used for the electro-puncture of aneurisms. Having first carefully disinfected the needle, he plunged it into the substance of the spleen, leaving it there just long enough to be sure that it was in the right place. The procedure is almost painless. In one of his cases Dr. Feletti had an opportunity of examining the organ after death, which occurred (from tuberculosis) a fortnight after the last puncture. With the naked eye, small brown spots could be seen in the spleen at points corresponding to the punctures. Microscopic sections showed a roughly triangular area with its base toward the capsule, which at that point was broken; this area

was occupied by young connective tissue, together with the remains of a blood-clot. In the discussion which took place on Dr. Feletti's paper, Dr. Fazio spoke highly of the results of parenchymatous injections of quinine in similar cases, which combined the mechanical effects of puncture with the medicinal action of the drug.—*British Medical Journal*, February 23, 1889.

Treatment of Pulmonary Abscesses.—Drs. Spillmann and Haushalter (*Revue méd. de l'Est*) lays down the following rules for the treatment of pulmonary abscesses.

1st. Before interfering surgically, one should assure himself, and especially by means of an exploratory puncture, of the existence as well as the locality of the abscess.

2d. When the diagnosis of an abscess is made during the course of a pneumonia, all methods of interference are to be avoided; should the pneumonia be cured and the abscess still persist, then intervention may lead to a rapid recovery, or at all events prevent grave accidents resulting from the opening of the abscess into the adjacent structures.

3d. Before opening the abscess it would be well to provoke or bring about pleural adhesions, if the same do not already exist.

4th. To find the abscess the best mode of procedure would seem to be costal resection and the opening of the lung with the thermo-cautery.

5th. Assist by means of tubes the thorough drainage of septic secretions, discard all antiseptic washings and use instead dry dressings.—*Revue de Thérapeutique*, February 15, 1889.

Trephining in Epilepsy.—Dr. Péan related, at the meeting of the Academy of Medicine last week, in his own name and in those of MM. Ballet and Gelineau, a case of partial epilepsy produced by a cerebral tumor in a man aged twenty-eight years, which was cured by trephining. The fits were marked by painful spasm of the right great toe, followed by stiffness of the corresponding lower limb, tonic convulsions, succeeded by clonic convulsions of this limb, which were afterward propagated to the arm and the face of the same side. Other symptoms appeared, which led the authors to suppose that the fits were due to a cerebral tumor situated at the level or in the neighborhood of the motor centre of the right inferior limb; it was, therefore, decided to resort to trephining. After the ablation of the neoplasm, which consisted of a fibro-lipoma developed at the expense of the pia mater, a drainage tube was left in the cavity produced by the tumor. The four fragments of the dura mater were sutured with catgut, and those of the scalp with the "hair of Florence," and then antiseptic dressing was applied. Eight days after the operation the threads and drainage tubes were removed; on the tenth day cicatrization was complete. A few convulsive twitches, probably due to the irritation of the cerebral substance, manifested themselves in the first few days following the operation. This was two months and a half ago, and two months subsequently to that date the patient did not present any epileptiform manifestations. The cure may, therefore, be considered complete.—*Lancet*, March 2, 1889.

Inhalations of Red Iodide of Mercury in Lung Tuberculosis.—Drs. Migual and Rueff, of Paris, after numerous and careful investigations, the results of which were most satisfactory, recommend inhalations of red iodide of mercury in lung tuberculosis. After the first *séance* the cough and the expectoration, in individuals with large cavities, were diminished, and the expectoration lost its offensive odor; with further treatment the night-sweats and fever disappeared; the general condition improved and the patients gained in body weight. The formula used was as follows:

℞.—Red iodide of mercury . .	1 part.
Iodide of potassium . .	1 "
Water	1000 parts.—M.

This solution was used as a spray, at the beginning once, and later on—when the patient had become accustomed to the irritation—twice daily; applied in this manner the red iodide is harmless. Should the inhalations become too irritating the solution may be weakened to 1 to 2000. The results obtained with this weaker solution will not vary from those obtained with the stronger one, as the red iodide of mercury kills bacteria in a solution of 1 in 40,000. One of the principal features of success in treatment depends upon the duration of the same, which can be prolonged for one year without doing harm.—*Wiener med. Presse*, February 10, 1889.

On the Rapid Curative Treatment of Cystitis.—Dr. Thomas More Madden recommends, in the *palliative treatment* of uncomplicated cystitis, long-continued warm baths, washing out the bladder through a double catheter with plain warm water, thin flaxseed tea, or a solution of boro-glyceride; conjointly in all instances with absolute rest in bed, the free use of diluents, together with the administration of the old-fashioned Dover's powder in small, frequently repeated, doses, as the best opiate in these cases; and lastly, above all, the use of boracic acid in ten or fifteen grain doses three or four times a day, by which the generally fetid ammoniacal urine is deprived of its fetor and rendered less irritating to the endovesical mucous membrane.

In the *curative treatment* he has abandoned the operation for the formation of an artificial vesico-vaginal fistula, through which the urine may drain away as fast as secreted, believing that we may obtain all its advantages more easily and more safely, simply by so thoroughly dilating the urethral canal with the instrument exhibited as to enable us to pass the index into the bladder, and thereby paralyze the contractility of the sphincter of the canal for a time, which may be indefinitely extended by repeating expansion in the same way as often as may be necessary. It may, moreover, be advisable in some instances to remove the proliferating vesical mucous membrane by the cautious employment of a dull wire curette, the author's, which he used with advantage in cases of this kind. And, lastly, whether the curette be required or not, the method of dilatation just described should, in all cases, be conjoined with the topical application of carbolic acid to the mucous surface. The latter is best employed in the form of glycerine of carbolic acid of the *Pharmacopœia*, which is quite strong enough for this purpose, and introduced by an ordinary stilette, armed with a piece of absorbent cotton saturated in the application, and passed through the dilator so as to avoid any of the acid being brushed off in the canal until it reaches the fundus vesicæ, where it should be

retained for a couple of minutes, until every part of the vesical wall contracts firmly upon it. The urethral canal is then to be similarly brushed out by another application of the carbolized glycerine. The pain caused by this procedure may be prevented by previously introducing in the same way a ten per cent. solution of cocaine. This plan of treatment now recommended seldom requires to be repeated more than two or three times, at intervals of a week, to effect a cure of even the most aggravated cases of cystitis in women.—*British Med. Journal*, March 2, 1889.

For Fissured Nipples.—

℞ —Cocaine . . . . . grs. x.
Lanoline . . . . . ℥j.—M.

To be applied once or twice daily. The ointment to be washed off before nursing.—*New York Medical Journal*, March 9, 1889.

Phenacetine and Antipyrine.—PROF. MASIUS, of Liége, has communicated to the Belgian Academy of Medicine the results of a somewhat extended trial of phenacetine which he has been making in his wards during several months past. In fevers of all sorts a reduction of temperature could generally be obtained by suitable doses; usually a dose of from fifty to seventy-five centigrammes was sufficient for this purpose; it was found that the same effect could not be produced by smaller quantities, even when given repeatedly. Two grammes during the twenty-four hours sufficed to keep the temperature down. The patients said that they felt a great deal better as the temperature fell; the pulse, too, became slower and stronger, and appetite and sleep returned under the influence of the drug. M. Masius also employed phenacetine as an analgesic not only in rheumatic, but in various other cases, with considerable effect. He did not, however, find that in this respect it was equal to antipyrine. It has been claimed for phenacetine that it has several advantages over antipyrine, such as more rapid action and an absence of disagreeable secondary effects, but according to the experience of M. Masius, though it is true that the lowering of temperature is more rapid than with antipyrine, it is of much shorter duration, besides which there is a liability to the occurrence of rigors and cyanosis, and neither its antithermic nor its analgesic action is so well marked as that of antipyrine. It has certainly the advantages of not disordering the digestion and of being cheap.—*Lancet*, March 9, 1889.

Lanolin Ointments.—DR. E. STERN recommends in the *Ther. Monatsh.* for February, 1889, the following lanolin ointments, which in his hands have given most excellent results. The first one spoken of is *Sapolanolin* ointment, composed of lanolin two and a half parts, and sapo viridis two parts. With the exception of salicylic acid, all other preparations, such as boracic acid, tar, white precipitate, resorcin, etc., can be easily added to this mixture. In eczema, mycosis, and in cases of seborrhœa with strong crust deposits such ointments will be found of great service. The following is the formula generally used by the author in psoriasis capitis:

℞.—Ammoniated mercury . . 10 parts.
Green soap . . . . 40 "
Lanolin (anhydrous) . . 50 " —M.

The action of sapolanolin with ammoniated mercury when applied to the head is as efficacious as chrysarobin upon the body. After having continued its use from three to eight days all signs of scurf will have disappeared, the affected portions will appear smooth and white and the application of some lanolin cream and daily washing with soap and water is all that will be required to give to the scalp its normal appearance. Discoloration of the skin was never observed. The author uses the following paste, which will adhere to the skin without any bandage:

℞.—Cold cream, Lanolin (anhydrous) } āā 40 parts.
Benzoated olive oil . . 20 " —M.

This forms a yellow ointment which permits of being applied to the face in thick layers. It is very adherent, wherefore the term unguentum adhæsivum would not seem out of place. To it can be added any other medicament. Should tar be added, the quantity of wax must be increased. The author uses this paste alone or in combination with boric acid and oxide of zinc in all cases in which the application of an ointment and bandage might prove of some difficulty, as for instance in the facial eczemas of children. This paste answers in these cases the purpose of maceration and of a new epidermis, so that at the end of eight or fourteen days the tar treatment may be commenced. In the squamous and vesicular varieties of eczema the addition of salicylic acid to this paste will be found of the greatest service:

℞.—Salicylic acid (finely powdered) 3 parts.
Olive oil . . . . . 17 "
Cerate, Lanolin } . . . āā 40 " —M.

For urethral injections the author prescribes the following:

℞.—Lanolin (anhydrous) . . 25 parts.
Almond oil . . . . 75 " —M.
(Basis-injection.)

or

℞.—Sulphate of zinc . . . 1 part.
Water . . . . . 9 parts.
Lanolin (anhydrous) . . 40 "
Almond oil . . . . 150 " —M.

or

℞.—Salicylic acid . . . . 1 part.
Almond oil . . . . 300 parts.
Lanolin (anhydrous) . . 99 " —M.

The injections are made with an ordinary syringe, the injected material being held from five to ten minutes in the urethra; its action is mild and not irritating. After twenty-four hours fat particles are found in the urine and this long retention accounts for the favorable action of this remedy upon the gonorrhœic processes. At the end of eight to ten days the author adds an antiseptic or astringent remedy to the injection, and ends the treatment with injections of a one and a half per cent. resorcin solution in water. Also in chronic urethritis lanolin injections are of great service.—*Wiener med. Presse*, Feb. 24, 1889.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE . . . . . $5.00.

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

SATURDAY, MARCH 30, 1889.

TREATMENT OF APOPLEXY DUE TO HEMORRHAGE FROM THE MIDDLE CEREBRAL ARTERY BY COMPRESSION OF THE CAROTID.

IN the *British Medical Journal* of March 2, 1889, is an extremely interesting report to the Scientific Grants Committee of the British Medical Association, by MR. WALTER G. SPENCER and PROF. VICTOR HORSLEY, suggesting that in cases of apoplexy (especially of the ingravescent form) which usually arise from hemorrhage of the middle cerebral, or its branches, that compression of the common carotid shall be employed as a means of arresting the hemorrhage, and of preventing the more serious consequences that would follow its continuance. Of course, in cases of hemorrhage from the middle cerebral, or from any other intra-cranial artery, arising from violence, in which the site of the hemorrhage could be ascertained, the proper treatment would be to open the skull and secure the vessels just as in any other part of the body. But this paper does not regard the question of traumatic hemorrhage, but of hemorrhage from apoplectic causes.

Clinically, such cases may be divided into three classes: *First*, those in which so much blood is poured out that death is immediate. *Secondly*, those in which the hemorrhage is so small that it ceases immediately. In neither of these would the proposed method of treatment be applicable. The *third* class of cases are those in which the hemorrhage is moderate at first, and continues for a longer or shorter time, during which the severity of the symptoms gradually increases, these symptoms being spasms followed by paralysis, dilatation of the pupils on the same side as the hemorrhage, and general signs of compression of the brain, followed by mechanical asphyxia and death.

The paper follows three lines of thought. First, anatomically, there is a sharp distinction between the relation the middle cerebral artery bears to the carotid, and the relation which the arteries forming the circle of Willis bear to the same vessel. The middle cerebral is not a part of the circle of Willis, but is the direct continuation of the carotid, ascending almost vertically in the fissure of Sylvius, and dividing into several branches which supply the ganglia at the base of the brain and the internal capsule. One of these—the lenticulo-striate artery—is again the most direct continuation of the middle cerebral, and is so much more frequently the site of lesions causing apoplexy that Charcot has well called it the "artery of cerebral hemorrhage." The circle of Willis, on the contrary, lies almost in a horizontal plane instead of a vertical one. Its vessels are not the direct continuation of the carotid, but are almost at right angles to its general axis, hence, the force of the blood is spent chiefly on the middle cerebral and its branches, instead of on the circle of Willis.

Secondly, pathological observations as to the site and the frequency of intracranial hemorrhages exactly tally with these *a priori* conclusions drawn from the anatomical disposition of these arteries.

Thirdly, Spencer and Horsley have now added experimental results of extreme interest and importance. The cerebral circulation in the Macaque monkey differs very much from that of the dog, rabbit, or horse, and is arranged on the same plan as in man. The animal having been etherized, the skull over the area supplied by the middle cerebral artery removed, and the dura raised carefully, the condition of the circulation and the pulsation of the vessels were first noted. The carotid on the same side was then compressed through the tissues of the neck against the vertebræ. Immediately the pulsation in the branches of the middle cerebral ceased. The vessels were not entirely emptied, but no pulsation could be seen even in the largest of them, and the cortex became distinctly paler. Relaxation of compression was followed by return of pulsation. This was repeated again and again with the same result.

Another series of experiments showed the effect of cutting off the blood supply. When a motor area is stimulated repeatedly by a Faradaic current the functional activity of that area becomes gradually exhausted, so that the minimal current which will produce movement has to be increased until at last even the maximum current is followed by no movement and complete exhaustion has been produced. Spencer and Horsley selected the centre for the angle of the mouth. When the blood supply was cut off the excitability was practically and immediately lost, but gradually returned as the circulation was restored. If compression of the carotid be continued for a considerable time, the anastomosing vessels of the circle of Willis gradually fill the middle cerebral and its branches, and the authors found that, two hours after ligation of the common carotid, pulsation in the middle cerebral was slight but not well marked, and the natural color of the cortex had been restored. When the corresponding cortical areas were then stimulated they reacted normally to minimal currents. Sudden or acute compression of the carotid, therefore, cut off the blood supply to the cortex and abolished its excitability for a time; but after the circulation had been gradually restored by anastomosis the cortex again became functionally active. This explains the immediate but temporary paresis of the face, arm, and leg which has occasionally been seen after ligation of the common carotid. Of course, the later cerebral symptoms noticed in about one-fourth of the cases, a day or two after the operation, cannot be referred to this cause, but are referable, the author thinks, to septic inflammation. While this is sometimes true, it is certainly not always the explanation. In some cases at least it is due to degenerative changes from insufficient blood supply. In cases of an insufficient anastomosis through the circle of Willis this may go so far as to produce necrotic changes.

Another interesting series of experiments—indeed the crucial ones—was made as follows: A large portion of one hemisphere of the cerebrum was exposed and a ligature was passed under the common carotid but was not tied. A rapid horizontal incision was then made in the hemisphere, so as to cut across the main trunk of the middle cerebral, the lenticulo-striate, and a number of other branches of the same artery running vertically upward, especially through the lenticular nucleus. The upper border of this incision being lifted, showed the middle cerebral and lenticulo-striate artery bleeding freely. Compression of the carotid immediately caused cessation of the bleeding. The small branches stopped usually at once, but the middle cerebral first stopped pumping, and then oozed freely. Soon the hemorrhage was arrested by a clot which, in from one-half to three-fourths of a minute, stopped all hemorrhage from the middle cerebral itself. Compression of the carotid was maintained two minutes and then released. The middle cerebral pulsated plainly under the thin clot covering its mouth, but no recurrence of the oozing ever occurred. The clots were then raked from the mouths of the vessels, which began to bleed as freely as before, when renewed compression was followed by renewed arrest of the hemorrhage. This could be repeated again and again. If the carotid was compressed before cutting the vessels across, only oozing occurred. This stopped as quickly as before. Raking the clots from the mouths of the vessels, the carotid being still compressed, only slight oozing took place, and was speedily arrested.

The authors propose that persons who are instructed in "first aid" to the injured should be taught to compress the carotid in cases of supposed apoplexy. They point out that the only confusion of a diagnostic character likely to occur would be between apoplexy and embolism or thrombosis; but very properly they call attention to the fact that compression of the carotid would not have any unfavorable influence in case of such a mistake in diagnosis. It is, however, chiefly to physicians that we must look for the use of this method of arresting cerebral hemorrhage or of limiting its ravages. The authors propose that, if time and opportunity allow, the carotid might be temporarily compressed by exposing it, passing a stout ligature under it, and then drawing the vessel against the finger by the ligature. In such a procedure the wound must be kept aseptic, of course, and the pressure must not be sufficient to injure the internal coat. Certainly, however, we cannot expect that many cases will give time, opportunity, and an antiseptic surgeon for such operative procedure, and the usefulness of the proposed compression of the carotid will be limited to a very small number of cases most favorably situated. It is a very possible thing, however, that in some cases of very severe hemorrhage or of high vascular tension, as well as in other directions as yet uususpected, that these very interesting experiments may bear fruit. In another class of cases we would suggest that occasionally temporary compression of the carotid may

be of value, viz., in those cases of intense headache in which apoplexy is threatened, or in which the patient's discomfort is extreme. Not only, however, does compression of the carotid influence the circulation in the brain, but, as the late Prof. S. H. Dickson frequently showed his friends in his own person, by compression of the carotid he could at will reduce his pulse at least twenty beats in the minute—a result that followed the compression almost immediately. Probably, however, this was a personal idiosyncrasy; but it is one worthy of further investigation.

SULPHONAL.

So much has been written and said in society meetings as to the value of sulphonal as a hypnotic, that it would seem to be impossible to add anything more to the subject, save by reporting more cases in which it has done good. One of the best summaries of all that has been done has been gathered together by Kronfeld and Löwenthal of Prof. Meynert's clinic, and, in addition, they detail quite a number of cases for themselves in the *Wiener klinische Wochenschrift* of January 10, 1889. Their patients seem to have suffered from almost everything that can produce sleeplessness, from old age to uterine cancer, a very large number of nervous cases being included, of a functional and organic character. The drug was given at about seven in the evening, and nearly always with the effect of causing sleep.

In *Nouveaux Remèdes* of January 24, 1889, are given the records of a meeting of the Société de Thérapeutique, held on January 8, 1889, at which Constantin Paul stated that sulphonal was the equal of chloral, and that it produced sleep with unusual speed and certainty. The report of Huchard was not so good, for while he found that it quieted patients, they did not always sleep, and this was so particularly in phthisis. He believes it to have little if any analgesic properties, and that the sleep produced generally lasts from four to eight hours after large doses. Huchard asserts also that it produces its most agreeable effects in essential insomnia. He does not believe that it is superior to chloral.

It is stated that the Board of Regents of the University of Michigan will ask the State Legislature for $50,000, to which will be added $25,000 by the city of Ann Arbor, for a new hospital building, with a view to increase the clinical facilities in connection with medical teaching at the University.

The fortieth annual meeting of the American Medical Association will be held at Newport, R. I., on June 25th, 26th, 27th, and 28th, under the Presidency of Dr. W. W. Dawson, of Cincinnati. Dr. Horatio R. Storer, of Newport, is Chairman of the Committee of Arrangements. In connection with the meeting there will be held an exhibition of medical books, appliances, drugs, etc.

The annual session of the Medical Association of the State of Mississippi for the current year, will be held in the City of Jackson, commencing on April 17th, at noon, and continue three days.

The South Carolina Medical Association will hold its next annual meeting at Charleston, S. C., on Wednesday, April 24, 1889. An address will be delivered by Dr. Robert Battey, of Rome, Ga.

The Lomb Prize Essay on "Practical Sanitary and Economic Cooking for Persons of Small Means," has been awarded by the American Public Health Association and will soon be issued, the value of the prize this year amounting to $500. The Secretary of the Association writes that the prize committee regard the essay as of unusual merit, and asks that it be not unfavorably prejudged by those who have seen the mutilated reprint of it in one of the daily papers of New York City.

The Royal Medical and Chirurgical Society, of London, has just purchased a large house in Hanover Square, which is said to be admirably adapted to the Society's wants. The property will be at once altered, and in all probability before the end of the year the Society will abandon its old quarters in Berners Street for its new and more commodious building. The Society's library now numbers 31,320 volumes.

The Emperor of Austria has conferred on Pasteur the order of the Crown of Iron, which gives him the right to the title of Baron and the insignia of nobility.

A cablegram from the Hague, dated March 25th, announces the death of Professor Francis Cornelius Donders, the eminent ophthalmologist, aged seventy-one years. Donders was born at Tilburg in Brabant, May 27, 1818. He studied medicine at the Military Medical School at Utrecht, became

military surgeon at the Hospital of the Hague and afterward professor at the Utrecht school. Called to the University of the same city, he was successively professor of histology and physiology, and then of ophthalmology, to which was added the clinic of diseases of the eye. In 1863 the government voted him a sum of money to construct a physiological laboratory corresponding to the needs of modern science. His researches on the "Anomalies of Refraction and Accommodation" placed this most important branch of ophthalmology upon a scientific basis and gained for its author a world-wide reputation. Donders was elected a member of the Institute of France in 1879, and he was also a member of many of the scientific societies of the world.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, March 21, 1889.

THE PRESIDENT, ALFRED L. LOOMIS, M.D., IN THE CHAIR.

DR. M. ALLEN STARR read a paper on

THE PHYSICS AND PHYSIOLOGICAL ACTIONS OF ELECTRICITY.

(See page 339.)

DR. LANDON CARTER GRAY then spoke on

THE EFEECTS OF ELECTRICITY IN CENTRAL NERVOUS DISEASES.

Before commencing, he stated that theoretically he entirely agreed with Dr. Starr in the position that he took, but as to practical results he differed very greatly from him, since he had reason to be well satisfied with those he had met with in sixteen years of daily experience. Dr. Starr had said that electricity could by no means be administered with the same certainty of effect as opium, for instance, but his experience had taught him that it could. In certain conditions he was just as confident of securing relief by the use of electricity as in others he might be by the employment of opium or quinine. Among them might be mentioned some forms of neuritis and of neuralgia of the trunks and extremities, some simple forms of neurasthenia, and also certain morbid symptoms of some of the organic diseases, although he would not have it understood that he claimed to cure the organic disease itself by this means. A great deal depended, he thought, on the way in which the electricity was administered, and he had never yet seen a dispensary which was properly equipped with apparatus for its careful and scientific use. Among the essentials requisite for this cure were a more or less constant cell (an absolutely constant one could hardly be obtained), a milliampèremeter, and a rheostat. Until within quite a short time the employment of electricity in America had been almost entirely empirical.

He had been in the habit of employing electricity in two classes of central diseases: *first*, the insanities, and, *second*, gross diseases of the brain. In the insanities which he had designated as functional, it had proved of great service in the convalescent stage, but he never employed it in the acute stage of such affections. Among the forms of insanity in which it was beneficial were melancholia, mania, etc. In speaking of the use of electricity in gross diseases of the brain, he referred particularly to intra-cranial syphilis. In the early stage of headache, before paralysis occurred, it was often very useful; as sometimes also in the later stages, after the occurrence of hemiplegia. In *tic douloureux* its action was somewhat uncertain, but its employment was sometimes attended with benefit. He wished to state, however, that he had no faith in the value of static electricity, except as regards the moral effect of its application in certain hypochondriacal cases or others where a strong mental impression was desirable.

The insanities were concerned only with intra-cranial conditions, and were best treated by means of galvanism. The gross disease of the brain, on the other hand, had two great classes of symptoms, *first*, cerebral, and, *second*, those both cerebral and peripheral. For the cerebral symptoms galvanism was best adapted, and for the peripheral, faradization. In employing central galvanization great care should be used to avoid anything like a shock or the production of flashes of light; and from one to two milliampères was usually all that could be comfortably borne by the patient. At first the sittings should not last more than three minutes, and in discontinuing the application the current should always be very gradually diminished. In applying faradization for peripheral symptoms the motor points could be readily picked out. The question naturally arose: Which pole of the battery should be used? It was an unquestionable fact that there were marked chemical and physiological differences in the action of the two poles, but as to their practical effects in the system from a therapeutic point of view, he was free to confess that he had never been able to convince himself that there was any advantage in one over the other. The only rule that he could lay down was, that if one pole did not suit the case, try the other, and if the other produced no better result, to abandon the use of electricity altogether.

In general paresis electricity was of no service, but in some cases of cerebral syphilis, where the symptoms were difficult to distinguish from those of general paresis, it was often of great benefit. In cases of hemiplegia without contracture it was also beneficial.

DR. W. R. BIRDSALL spoke of

THE EFFECTS OF ELECTRICITY IN DISEASES OF THE SPINAL CORD.

As to organic diseases of the cord, he said that he agreed with Dr. Starr in his doleful picture, only he could apply it to other therapeutical means as well as electricity, and consequently he thought the statements of the paper were an injustice to the latter agent. When we considered the condition present (this being a class of diseases that were practically incurable), we should not expect too much. Like Dr. Starr, he had never seen a case of such organic disease cured by electricity; but he would go further, and say that he had never seen a case cured by any other means. But at the same time he had

often seen the use of electricity attended with good effects in these cases. We had to treat the symptoms, the pain, the spasm, the paralysis; but as to removing or shortening the process underlying the symptoms, it was certainly difficult to point to any agent whatever that would accomplish this result.

The rule might be laid down that electricity is not to be resorted to in any acute inflammatory condition. Here it was liable to do harm, instead of good, and, as a rule, it should not be employed in inflammatory affections at all. As to the effect of electricity upon the system, it seemed to him that it was that of a stimulus. While clinical experience appeared to favor the idea that we can accomplish more with the anode than with the cathode, practically he thought there was but little difference between the two. In using electricity in any form, it was important that both the immediate and the after effects should be taken into consideration, and he believed that we really know more about the effects of this agent than even about those of the most familiar drugs. But neither in the case of drugs or of electricity could we always tell what the ultimate effects would be on the system.

He believed himself that a large share of the electricity was reflex in character. For this reason an argument could not be raised against the use of statical electricity because its local action was superficial, and he considered it an agent of decided force. When we come to consider the effects of electricity upon the spinal cord, he agreed with Dr. Starr that by the ordinary means of applying it only full currents acted upon the cord; yet, at the same time, he could not doubt that powerful effects often resulted. It was a fact that when one electrode was placed at the nape of the neck and the other upon the arm, and a current of twenty milliampères was used, a flash of light could be produced; showing that the optic apparatus had thus been indirectly affected. The tissues of the head were thus implicated, although the current did not pass directly through them. The resistance of the skin to the passage of the current was greater than that of any of the other tissues. The main effects on the spinal cord, he believed, were the peripheral effects. In tabes he had seen relief from pain to a moderate degree afforded by electricity, but had never known any effect to be produced upon the ataxia. In certain cases, however, he had seen some improvement in spastic conditions, and in this connection he referred to a case where the spastic condition followed upon transverse myelitis. The best effects were noticed in instances where the structural changes were not complete, and the nutrition of the muscles was not too greatly impaired. In facial paralysis and head paralysis, he had often seen great improvement take place under the use of galvanism. The principal effects to be hoped for from electricity were improvement of paretic conditions, relief of pain, relief of spasm in certain instances, and the benefiting of functional derangements.

Dr. A. D. Rockwell then read a paper on

THE EFFECTS OF ELECTRICITY IN PERIPHERAL NERVE LESIONS.

The best results from electricity, he said, are met with in functional disorders; but even here discrepancies are often met in different cases, and a brilliant result obtained in one patient might be followed by comparative failure in another apparently suffering in the same way. Facial paralysis was among the more important peripheral nerve affections, and in a large number of cases he had seen great benefit derived from electricity. In others, however, he had been disappointed in his results. It was proper to inquire, therefore, (1) Does electricity sensibly hasten recovery in peripheral nerve diseases? and (2) in what cases is it to be tried? In many cases of diminished farado-muscular contractility with increased galvano-muscular contractility but little benefit was derived from electricity. As to facial paralysis, if the portion of the nerve external to the Fallopian canal alone were affected, marked relief would be apt to attend the use of electricity; but if the portion of the nerve lying within the bony canal were compressed by inflammatory products not much could be expected from it. In diphtheritic paralysis he had often found it of very great service.

Dr. E. D. Fisher read a paper on

THE EFFECTS OF ELECTRICITY IN FUNCTIONAL NERVOUS AFFECTIONS.

In functional disorders, he said, we had to assume a molecular or fine nutritional change, and in electricity we had an agent which acted as a stimulant to the normal functions when these were functionally deranged. In this class of affections much, then, could be accomplished by it, and it was to experience that we look in order to appreciate its true value. In static electricity, with which he had had considerable practical experience, we had an agent ordinarily well adapted to stimulate the surface, and he had found it of considerable service in the treatment of such conditions as cerebral and spinal neurasthenia, chorea, etc. While faradization was also often of advantage, the greatest benefit to be derived in this class of cases in general was from galvanization. Physiological data, borne out by clinical data, would seem to sustain the positive value of electricity in functional diseases.

He would not discard the use of statical electricity altogether, as he believed it had its place in the list of therapeutic agents of advantage in functional diseases, where the trouble was nutritional, and not organic.

Dr. M. P. Jacobi made some remarks on the treatment of uterine fibromata by means of electricity, and said that he had been very much disappointed in trying to get out accurate statistics from which some definite conclusions as to the value of this method might be based. In the report of the hundred cases of Apostoli published four years ago there was much that was open to criticism. The data given were often meagre and unsatisfactory, and all the cases were reported cured as the symptoms were relieved. Keith, who was so impressed by the results of Apostoli's treatment which he observed in Paris that he stated that he would never advise laparotomy in any case of this kind until a thorough trial of electricity had been made, reported that he had made twelve hundred applications in one hundred cases, the majority of which were fibroids. He did not, however, give any accurate statistics, but merely stated that the tumors were reduced in size and that the cases were mostly relieved. After Apostoli and Keith the largest number of cases had been reported by Everett in the *New York Medical Journal*, in the paper which was doubtless familiar to

all present. There were seventeen cases in all; but six of them were either situated very near the mucous membrane or else were polypi. Faradization and galvanism were employed until the tumors protruded into the uterine cavity and they were then removed by operation. Another series, of sixteen cases, was reported by Webb, an Englishman, and three of these, which were of remarkable interest, he mentioned particularly. All Webb's cases were treated with galvano-puncture, although the procedure differed materially from that advocated by Kimball and Cutler some years ago. The puncture was always made through the fornix, and the needle was inserted but a short distance. In addition, galvano-cauterization of the interior of the uterus was practised.

DR. GEORGE W. JACOBY looked upon the whole subject of electro-therapeutics very decidedly from the standpoint of Dr. Starr in his paper. In employing electricity we are dealing with physiological effects of which we know very little. When one good observer told us that he had seen cures in certain diseases produced by it, and another equally good observer told us that he had never seen any benefit derived from it in the same affections, it was certainly difficult to arrive at any positive conclusions regarding the utility of this agent.

DR. L. PUTZEL said that the great trouble was that we do not take into account the natural history of the diseases in question. He agreed with Dr. Starr in the main, although he did not believe that the latter would wish that his paper should be regarded as a full statement of his views. He certainly did not believe that electricity could cure organic troubles, but at the same time he thought there could be no doubt that it often did relieve symptoms. Dr. Gray had expressed the opinion that the reason that better results with electricity were not obtained by many, was because it was given empirically; but in the present state of our knowledge he did not think it could be used in any other way. In order to get some idea of the practical value of electricity, we should compare cases treated by electricity with the same class of cases treated by other remedies, and left untreated. There was one point which rendered it difficult to say just how far any benefit observed was to be attributed to electricity, and this was that no disease was treated with electricity alone.

In the treatment of varicose veins he had found that the faradic current was of very great practical benefit. This he had discovered accidentally in a case of hemiplegia; and while the hemiplegia, for which the electricity was employed, remained unimproved, the varicose veins were cured by it. In this affection a good result might be expected if the veins were not too sinuous or not too greatly dilated. In applying the current it was his practice to begin at the lower part of the leg.

DR. JOHN H. GIRDNER believed that the electrical condition of the body in health and disease was a matter of great importance. In the action of the instrument which he had described two years ago for detecting the exact location of a bullet or other metallic substance embedded in the tissues, there was, he believed, a distinct electrical current taken from the body. More recently he had substituted for the telephone an electrometer, and for the probe another cell. He then exhibited zinc and copper rods adapted for introduction, the one into the mouth and the other into the rectum, to which wires could be attached, and said that by means of this device he had succeeded in getting a current from the body of the strength of one-fifth of a milliampère. He had thought at first that this electrical action might be due to the fact that one of the cavities into which the rods were introduced was acid and the other alkaline in reaction; but subsequent experiments had demonstrated that the current was produced entirely independent of the chemical reaction of the oral and rectal cavities.

In health, therefore, he believed that there was a constant electrical condition of the body, since by the means indicated we could undoubtedly develop a current which could be measured. He was convinced, also, that this electrical condition was different from what it was in health; or, in other words, that the electrical condition varied in health and disease. When we are able to ascertain just what these varying conditions were, we might perhaps be able to introduce into the system some kind of current that would be directly beneficial. This was a subject in which he was deeply interested, and in regard to which he was at present pursuing investigations which he hoped at some future time to embody in a paper to be presented to the Academy. He would only say, in conclusion, that he believed the time would come when in the treatment of disease it would be regarded as important to know the electrical condition of the body as it was to know the temperature.

DR. PETERSON said that for some time past he had been engaged in a series of experiments having in view the production of local anæsthesia by the introduction, through the cataphoric action of electricity, of cocaine and aconitia into the subcutaneous tissues. In many of the severer forms of neuralgia of the peripheral nerves which resisted other means of treatment he had used this method with decided benefit. By means of it he had succeeded in securing complete relief from pain for from five to eleven hours at a time. He did not believe, however, that it had any curative action, its effects being merely palliative.

DR. WILLIAM H. THOMSON said that the difference between the galvanic and the faradic current was, in his opinion, very material. The one possessed a powerful chemical action, and the other did not. He agreed with Dr. Starr as to the feeble powers of the galvanic current. On the other hand, the faradic current had a powerful stimulating effect upon all the bloodvessels situated between the two points where the electrodes were applied. In head paralysis he thought there was nothing that would drive the blood directly into the small muscles like the faradic current properly applied. The utility of this current in promoting absorption was also very great, as pointed out many years ago by Graaf and Langenbeck, the latter of whom used it with the most happy effects in an adenoid tumor of the neck. In his hands it had proved of the greatest possible service in the removal of exudations, and he constantly employed it in such affections as chronic muscular rheumatism, enlargement of the liver and spleen, and chronic effusion into the pleura. He should be very sorry, he said, to have his faith shaken in the efficacy of electricity in promoting absorption.

DR. ANDREW H. SMITH said that there was one condition in which he had found static electricity more promptly efficacious than any other agent with which he was acquainted, and that was muscular stiffness from exposure to wet or cold. Usually one application was

all that was required for its complete relief; but occasionally a second application was necessary. In regard to Dr. Girdner's device for procuring an electrical current from the body, he believed that the explanation of the production of the current was simply that a cell was created within the body by the means employed.

Dr. Starr, in bringing the discussion to a close, said that it seemed to him that the discussion had been unfavorable to many of the claims for the use of electricity made by many of the text-books. Gowers was the first to express the truth in regard to the effects of this agent, and he believed that he was entitled to credit for the bold and candid position that he had taken. While some of the speakers had taken a different view, there had been a pretty general consensus of opinion that these claims of cures by electricity were greatly exaggerated and without any adequate basis in fact; and he believed that this consensus would have weight with the profession at large as coming from this Academy. It was time that our physicians knew the truth about the matter, for patients were constantly being sent to this city at great expense and inconvenience expressly to be treated for electricity, when they could be just as efficiently treated by other means at home.

He thought that one very important point had been acknowledged by Dr. Gray, and that was that we do not know any therapeutic difference between the two poles. As it was a well-established fact that there was a very material difference in their chemical and physiological action, it seemed to him that the fact that there was no difference between them therapeutically showed that electricity was of but little value as a remedial agent. As to hemiplegia not followed by contracture, which Dr. Gray had claimed to cure by electricity, this was a condition in which recovery always occurred in the course of time, whether any treatment was adopted or not. It was acknowledged by all, however, that the growth and nutrition of muscles were promoted by electricity, whether of the galvanic or faradic variety; and this was well illustrated in the case of Dr. Thacher's to which he had referred. Diphtheritic paralysis, which Dr. Rockwell said could be cured with electricity, was another form of paralysis which always recovered of itself.

He wished to take exception to one statement made by Dr. Rockwell, viz., that faradic electricity acted on the intra-muscular nerves and that galvanic electricity acted upon the nerve trunks, and hence that a degenerated muscle failed to act to faradism. Both currents act on both parts. There is no essential difference in their action. But the reason faradism fails to act on a degenerated muscle is *not* because the intra-muscular nerves are diseased, but because the rapidity of the change of electrotonic state is too great in the faradic battery to elicit the contraction in a degenerated muscle or nerve. If a single shock of a faradic battery alone be given to a degenerated muscle it will react just as it does to an interrupted galvanic shock. It is the rapid alternation of shocks usually produced in the faradic apparatus to which the muscle is incapable of responding.

Dr. Fisher had also made two statements from which he must positively dissent. He had said that the nervous system was the best conductor; on the contrary, it was a very poor conductor. Again, he had said that the sympathetic was very easily affected by electricity; while, in reality, it was very difficult to do so, requiring a current of great strength, as was proven by the difficulty in producing pupillary contraction by galvanizing the cervical sympathetic. He agreed with Dr. Jacoby that it was very difficult to judge between different observers when their experiences were directly contrary to each other. Under these circumstances the consensus of opinion alone can decide. He was entirely willing to acknowledge the power of electricity in absorbing exudates, referred to by Dr. Thomson. Anything which would increase the circulation and improve the nutrition of the part would prove of service in this respect. He believed, however, that Dr. Thomson would get better results if he would employ the galvanic instead of the faradic current for the object named, since its catalytic action would aid the process. Dr. Starr agreed with Dr. Smith as to the explanation of the electrical current produced in Dr. Girdner's experiment.

PHILADELPHIA NEUROLOGICAL SOCIETY.

Stated Meeting, January 28, 1889.

The President, S. Weir Mitchell, M.D., in the Chair.

Dr. F. X. Dercum reported the following case of

SUPRA-DURAL HEMORRHAGE.

The patient was a man, thirty to thirty-five years of age, brought to the Philadelphia Hospital early one morning in December by the police patrol, he having been found lying upon an open lot. He was totally unconscious: temperature subnormal, registering at one time 95°; face flushed and dusky; breathing labored and stertorous, and at times resembled the Cheyne-Stokes respiration. The lips and cheek of the right side were puffed in and out and the right nostril dilated. The left side seemed normal. The mouth was not distinctly drawn. Both hands and arms were firmly flexed and crossed over the chest. They were decidedly rigid. The legs were also fixed in extension with some turning in of the feet. The head was turned to the right, a marked effort being required to rotate it toward the opposite side. The right pupil was widely dilated, while the right eye was directed outward, as though held there by spasm of the external rectus. The left pupil seemed unaffected. Both were insensitive to light. No response was evoked by irritating the conjunctivæ, and this was also true of the skin over the entire body. The arms could be partially extended, and occasionally jerking movements were observed in them.

The patient vomited freely, the ejecta smelling decidedly of whiskey. The urine, obtained by the catheter, contained no albumin. The pulse was weak and intermittent. A small scratch or abrasion was found to the right and above the occipital protuberance. It had bled little, if at all, and seemed very insignificant. No bleeding had occurred from either the ears or nostrils. The man's condition remained unchanged for several hours, but he gradually grew weaker as the day progressed, and finally died.

Autopsy: Beneath the bruise previously observed the inner surface of the scalp and the periosteum were ecchymosed. No fracture of the skull was, as yet, apparent, and no depression existed. On removing the calvarium, however, and examining its inner surface, a fracture was

detected beginning a little in front of the lambdoid sutures and extending obliquely outward across the serrations of the latter. It was evidently a fracture of both tables, and on the outer surface was now observed to be about an inch in length and linear in shape. The fracture of the inner table was much more extensive. It extended in three directions, the most complete break being along the line of the lambdoid suture.

Lying upon the dura an immense clot was found upon the side of and beneath the fracture, and situated over the lateral aspect of the superior and inferior parietal lobules, the first and second temporal convolutions, and the anterior extremity of the lateral aspect of the occipital lobe. The anterior limit of the clot was about one-half to one inch back of the fissure of Rolando, while its posterior limit was from one-half to one inch from the apex of the occipital lobe. In its middle portion the clot was fully an inch, if not more, in thickness.

An examination of the base of the brain revealed numerous ecchymotic spots and areas in the pia and arachnoid. Similar appearances were observed in the brain almost everywhere. No hemorrhage existed in the ventricles or ganglia. On the ventricular surface of the right caudate nucleus was an area of very superficial yellow softening one-half inch in length, one-fourth inch in breadth, and three or four lines in depth.

The fact of the limbs being rigid in contraction suggested semi-conscious resistance, and also the fact that the man was vomiting matter smelling of whiskey suggested that he was drunk. He undoubtedly was drunk in addition to having the extra-dural hemorrhage. The diagnosis was also complicated by the presence of specific scars over his person, thus suggesting a specific cause for the inequality of the pupils. I, however, could not free my mind from a suspicion of hemorrhage. I thoroughly examined the scalp, but did not feel at the time that the slight scalp wound was sufficient justification for trephining, but I think now that exploratory trephining would certainly have been rewarded. In explaining the symptoms in this case, it seems to me that the absence of hemiplegia was due to the fact that the clot was not directly over the motor area. The general rigidity is, probably, to be explained by irritation of the dura. The dilatation of the pupil was probably due to direct pressure.

DR. CHARLES K. MILLS saw this man for a few minutes on the morning that he was admitted, and expressed the opinion that the case was one of hemorrhage. The case is an important one, as it clearly confirms the diagnostic marks of Jacobson and others for supra-dural hemorrhage. Looking over the cases which he had collected for the paper read at Washington, he found a number in which the symptoms correspond somewhat closely to those described to-night. The dilatation of the pupil—the oculo-motor paresis—is so common that Jacobson suggests that it be called Hutchinson's pupil. it having first been described by that observer. He examined the oculo-motor nerve very carefully in this case at the autopsy; it did not differ from the other nerves at the base. He, therefore, thought that the dilatation of the pupil was the result of pressure. A considerable amount of pressure would be exerted on the entire hemisphere, and a clot in the position indicated might possibly cause paresis of the oculo-motor nerve by counter-pressure. He believed that in a case presenting these general symptoms, with paresis on one side, and suspected injury even without the external evidences present here, we would be justified in trephining over the parietal lobe, as has been done by Kronlein and others in such cases.

HEMORRHAGIC PACHYMENINGITIS.

DR. FRANCIS X. DERCUM, in a series of seventy-seven autopsies, the records of which, and the specimens of membranes of which he went over very recently at the Insane Hospital at Norristown, found twenty-eight cases presenting hemorrhagic pachymeningitis. In these twenty-eight cases there were four in which there were gross lesions, that is, there were large hæmatomata; in the others, there were fibrinous patches. Some of the patches were stained very slightly, while others were quite dense and heavily stained; all were more or less stained.

The frequency of the occurrence of this affection in the chronic insane is exceedingly interesting, and suggests that this hemorrhagic or *fibrinous* pachymeningitis, as it is perhaps better called, is an inflammation, so to speak, normal to the dura—*i. e.*, if we have a simple inflammation of the dura, it is always an inflammation with fibrinous exudation, with or without the formation of vessels. Looking over the recent publication of Hirt on nervous diseases, he found that, under the head of inflammation of the dura, in which he is supposed to consider only simple inflammation, he speaks only of internal hemorrhagic pachymeningitis, evidently considering this *the* inflammation of the internal dura, thus regarding all other inflammations as special forms.

DR. A. ESHNER, through the courtesy of Dr. Hirst, reported the following case of

HEMORRHAGE INTO THE CENTRUM OVALE OF THE POSTERO-FRONTAL AND PARIETAL LOBES.

E. L., an unmarried Englishwoman, aged thirty-three years, was admitted to the hospital December 18, 1888. She stated that she had been blind for three weeks. The ability to discriminate light remained. There was a moderate degree of anasarca, and examination of the urine disclosed a considerable amount of albumin, with hyaline and granular casts of the uriniferous tubules. On December 20th the external measurements of the maternal pelvis were made, the diagnosis of pregnancy confirmed, and the presentation and position established. The fœtal heart-sounds, however, were not detected. Upon the direction of Dr. Hirst, a hot-air bath was ordered, and the removal of the fœtus, which it was conceived was dead, was contemplated. Shortly preceding this examination, on December 20th, at about five o'clock in the afternoon, the woman developed a comatose condition, with stertorous breathing. She had sat up in a chair during the morning, had taken milk and medicine, and, in response to inquiries, had stated that she was feeling better than hitherto. The night before, she is said to have sat up in bed and combed her hair, though a neighboring patient observed convulsive muscular contractions of the arms and shoulders. Soon after the condition of coma was noticed, the patient was yet able to swallow and respond to calls. She made complaint of the disagreeable taste of the medicament which she was taking. She was given milk again at 9.30 P.M. and at 1.30 A.M., and medicine at 10.30 P.M. Urine was passed once, and the bowels moved twice involuntarily. She grew worse

during the night, and Cheyne-Stokes respiration set in. While preparations for a second hot-air bath were being made, at about 4.30 A.M., December 21st, the woman vomited a not large quantity of bloody fluid and expired. Unfortunately the nervous aspect of the case was not carefully studied. It is known, however, that the patient was able to move the right upper extremity until within a short time prior to death. On the night before, she appeared to have been oppressed by a sensation of subjective heat, as she removed the bedclothing from the chest.

The autopsy was made, under the direction of Dr. Mills, thirty-six hours after death. The only abnormal appearance on the surface of the brain was a large area of discoloration over the posterior part of the first and second frontal convolutions, at their junction, reaching, in the same plane, over the two ascending convolutions. On opening the right lateral ventricle, an irregularly shaped, longitudinal clot, about one inch or more in length, was found lying loosely in the cavity. This clot communicated with another, or with another portion of the same clot, which lay in a cavity which appeared to exist in the white matter external to and above the ganglia. Examination showed the ventricular surfaces of the caudate nucleus and optic thalamus entirely intact. The septum lucidum was not broken down, nor was there any blood in either the third or the left lateral ventricle. In fact, the entire left hemisphere appeared normal. A large section through the middle of the ganglia on the right side and the parietal lobe revealed a clot of the size of a lemon, confined to the white matter of the posterior frontal and parietal regions—the white substance of the corona radiating between the ganglia and the following convolutions: the posterior portions of the first, second, and third frontal, both ascending, and the superior and inferior parietal. Transverse sections in various situations through the ganglia showed no lesion. The ganglia were intact.

Hemorrhages into the centrum ovale and the cortex cerebri are relatively infrequent, though next in frequency of occurrence to those into the ganglia, which hold the first place.

Nothnagel, in Ziemssen's *Cyclopedia*, states that hemorrhages into the medullary substance may be wholly unattended with evidences of cerebral disease. In some cases an apoplectic seizure may occur, followed by complete recovery. In others there may be the usual evidences of hemorrhage, with or without apoplectic symptoms, followed by disorders identical with those following lesions of the corpus striatum. The symptoms of hemiplegia may be present and subsequently entirely disappear. This is perhaps the most characteristic feature of hemorrhage into the region under consideration.

Vasomotor disturbances and alterations of sensibility are sometimes present. Contractures are rarely noticed. The symptoms arising from affections of the centrum ovale bear the closest resemblance to those produced by disease in the corpus striatum.

Gowers states that hemorrhage into the centrum ovale causes symptoms similar to those due to a cortical lesion in the corresponding situation, but without the symptoms of irritation. Large hemorrhages usually spread into the centrum ovale from the corpus striatum. The vessels in the white substance are small and give only small hemorrhages.

DR. WM. OSLER said this case illustrates one of the conditions which in the pregnant woman may lead to hemiplegia or fatal hemorrhage. True apoplexy occurs most frequently in association with Bright's disease, and may come on during, or even be mistaken for, a uræmic attack. A specimen very similar to the one here shown is in his collection of brains in the Museum of McGill College—massive intraventricular hemorrhage. Rupture of a cerebral vessel during labor is, he believed, rare. A second more common event is embolism of one of the cerebral arteries during parturition. Aphasia is very often associated, and in a majority of the patients old mitral disease exists. In a limited number of cases a third condition is present—thrombosis of the cerebral vessels, due possibly to blood conditions which favor coagulation.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, March 18, 1889.

THE PRESIDENT, CHARLES S. WOOD, M.D., IN THE CHAIR.

DR. J. LEWIS SMITH read a paper on

THE CAUSE, MODE OF PROPAGATION, AND PREVENTION OF DIPHTHERIA.

Each year of recent investigation, he said, has strengthened the belief that the cause of diphtheria is a microbe; but it is still a matter of doubt which microbe is the causal agent, or whether there may not be more than one species of bacteria which by their action upon and in the tissues produce the disease. Having referred to the researches of Oertel (published in 1868 and 1874), Cohn, Eberth, Klebs, Senator, Billroth, Curtis and Satterthwaite, he said that the important observations and opinions expressed by Drs. Curtis and Satterthwaite in 1877 as the result of their investigation, under the auspices of the New York Board of Health, of the etiology and pathology of diphtheria, evidently prepared the way for the theory that the bacteria themselves are not the cause or the infectious principle of the disease, but that chemical substances, or ptomaines, produced by the agency of the bacteria, may be.

He then went on to speak of the more recent investigations of Wood and Formad, Klebs and Löffler, Cheyne, von Hoffman, Wellenhof, and Oertel; and stated that the latter, who was one of the earliest advocates of the theory of the microbic origin of diphtheria, now admits that the causative action of bacteria, though plausible, is not proven. The purpose of Oertel in his recent investigations has been to ascertain, if possible, the nature of the diphtheritic virus by a close and minute study of the lesions or anatomical changes which it produces; and the following is a summary of his present views. The nature of the virus is still obscure. It acts upon cells, causing their death and disintegration, and the infected particles convey the virus to other cells. The virus causes hyaline-degeneration in the tissues. The hyaline degeneration in the walls of the bloodvessels causes them to rupture, producing hemorrhages. The unequal amount of hyaline change in different parts of the vascular apparatus may be attributed to difference in resisting power or unequal exposure to the infected blood. Secondary inflammatory processes in the lungs, heart, liver, kidneys, and central and peripheral nerve-tissues must arise from the infec-

tious property of the blood circulating in them. He expresses the opinion that bacterial organisms cause diphtheria, and that they do so, not by their direct action, but by producing a ptomaine which infects the system and causes the disease to be constitutional. The microbe itself is mostly confined to the surface, where the action of the virus is widespread and deep. The most eminent pathologists of the present time, said Dr. Smith, do not express any more positive opinions in reference to the action of the specific principle or germ of diphtheria.

At the recent meeting of the London Epidemiological Society, Dr. M. W. Taylor stated his belief that common mould might sustain a causal relation to diphtheria, citing several instances which apparently favored this hypothesis. The theory that organisms which are commonly present in ordinary mould can produce diphtheria Dr. Smith thought improbable, however, since mould is common in all damp localities, where there is no diphtheria as well as where the disease is present; and he believed that the cases referred to by Dr. Taylor were explainable in other ways. The specific principle must be introduced from without, but if it obtain a lodgement upon the wet and mouldy surface of any filthy accumulation, it may find there a nidus favorable for its development. The fact appears to be fully established, as would be shown later on in the paper, that the diphtheritic virus is frequently propagated in foul and damp localities, apart from the animal tissues and independently of the sick. He repeated, therefore, that the theory of the causation of diphtheria which is gaining acceptance throughout the world is, that it is produced by a specific microbe or microbes, whose action is chiefly on the surface, or at no great depth, and that blood-poisoning occurs mainly from a ptomaine or ptomaines produced by microbic agency. In order to obtain a knowledge of the ptomaines, chemistry must aid microscopical investigations. During the past year Dr. T. Mitchell Prudden, whose care and trustworthiness in pathological research are universally recognized, has been making a series of elaborate investigations, the results of which will shortly be published in the *American Journal of the Medical Sciences*, and which seem to indicate the strong probability that the specific microbe of diphtheria is a streptococcus.

Mode of propagation. No fact is better established than that diphtheria does not arise *de novo*. Like the eruptive fevers, it is produced by the reception in or upon some part of the system of the preëxisting specific poison. The extreme contagiousness of diphtheria from person to person is well known, and the virus adheres tenaciously to objects on which it happens to alight. The clothing of a patient, even when the disease is of the mildest form, his bedding, the furniture of his room, and the objects which he handles may for weeks afterward communicate the disease. Dr. Sternberg, in his recent Lomb Prize Essay, also alludes to the fact that all damp, foul floors, such as sewers, cellars, and ill-ventilated spaces under floors, afford conditions favorable for the development and propagation of the diphtheritic virus. The virus, whatever its nature, once received, may be propagated in such a place for an indefinite time, and, ascending in the vapors which arise from this culture-bed, it is liable to communicate the disease to anyone who inhales it. Thus, in New York city, prior to 1850, although foul sewers and insanitary conditions existed, there was no diphtheria; but in the decade following 1850 the disease was introduced. Its germ made its way into the sewers underground, and now wherever sewer-gas escapes into the domiciles of the city it carries with it the diphtheritic virus. The amazing vitality and power of propagation of the diphtheritic poison are apparent when we reflect that it has permanently infected the New York sewers; so that children in all parts of the city are constantly falling ill with the disease, contracted by inhaling sewer-gas, which, notwithstanding "sanitary plumbing," often escapes from unsuspected sources. It is chiefly by exposure of children to the emanations from this widely extending culture-bed, and to walking cases, often so mild that there is little or no complaint of the throat or impairment of the general health, that diphtheria is so prevalent in New York. The diphtheritic virus is so subtle, and its vitality and power of propagation so great, that when it is once established in a sewered city the disease can probably never be stamped out, as cholera and yellow fever can.

Diphtheria is commonly communicated by the inhalation of air containing the specific principle of the disease, from whatever source the latter may be derived. More rarely the contagion is derived by direct contact with some infected solid substance, such as a particle of the diphtheritic exudate, muco-purulent secretion from an infected surface, or the blood of a patient. Observations are also accumulating which show that diphtheria, or disease closely resembling it, occurs among animals, and is sometimes communicated from them to man. The feathered tribe especially appear to be susceptible to this disease. Having described the introduction of diphtheria into the island of Sciathus, off the coast of Greece, apparently by means of some turkeys brought from Salonica, he quoted M. Menzie's authority for the statement that the disease is common among the poultry of Italy, and mentioned that a number of instances in which diphtheria appeared to be transmitted from animals to man were given in a paper by Dr. Delthil published in Paris in February, 1889. He next referred to instances in which it was apparently communicated by pigeons and fowls, as reported by Dr. F. F. Wheeler in the *American Practitioner and News* and Dr. George Turner in the *Journal of Laryngology and Rhinology*.

He then spoke of experiments by different observers which would seem to show that diphtheria can be transmitted from man to animals, and stated that if this were true, it could be inferred that it might likewise be transmitted from animals to man. Such observations and experiments, he went on to say, render it probable that genuine diphtheria, equally fatal, and attended by the same symptoms and anatomical characters as in man, does occur in birds, whether wild or domesticated, and in certain quadrupeds, as the rabbit. Nevertheless, it should be added that certain eminent pathologists, among them Virchow, have doubted the identity of animal and human diphtheria.

With our present light upon the subject, he thought it was evident that, since our relations to the domestic animals are so close, if they are sick with any disease resembling diphtheria the same precautionary measures should be taken to prevent infection of the family as in human diphtheria. Milk is a culture-medium of various microbes, and that it may be the medium of communication of diphtheria, as well as of scarlet fever, seems

probable. In this connection Dr. Smith referred to several instances of such apparent communication observed by different writers.

The fact that the diphtheritic virus may be conveyed long distances without losing its power is now admitted from the many observations that have been made, and the statistics given by Prof. C. W. Earle, of Chicago, in his paper on this subject before the Ninth International Congress, render it probable that the diphtheritic infection is not infrequently transmitted over long distances to salubrious rural localities by means of articles of clothing and merchandise.

Prevention. As regards the small extent of the area of its contagiousness and the persistence and highly infective character of its virus within that area, diphtheria resembles scarlet fever, and is unlike measles and pertussis, the specific principles of which, although they have a wider contagious area, are more volatile and more quickly dissipated. The most efficient method of preventing the propagation of diphtheria is the isolation and disinfection of patients, the prompt and thorough disinfection of the apartments in which they have been treated, and of the bedding and furniture of these apartments, and the exclusion or prevention of all noxious gases. Dr. Smith thought there was reason to believe that disinfection, as commonly practised, is inadequate, and in illustration he referred particularly to an epidemic of diphtheria occurring at the New York Infant Asylum in the spring of 1888. In the vacated ward forty pounds of sulphur, or two pounds to the 100 cubic feet, were burned until it was consumed; yet after the fumigation cultures made from dust derived from the floor and bedding produced a large number of microbes, among which Drs. Prudden and Cheeseman were able to distinguish the *streptococcus pyogenes*, identical in form and appearance with the streptococcus which they had previously discovered in two fatal umbilical phlegmons which had occurred in the ward in connection with diphtheria. Although more sulphur was used than is recommended and employed by the New York Board of Health, and in the manner recommended by the Board, it was inadequate to destroy the microbes.

It was evident that some more efficient mode of domiciliary disinfection was required, and Dr. Smith applied to Dr. E. R. Squibb, the eminent chemist, of Brooklyn, to obtain his views on the subject. Dr. Squibb wrote that, in our present state of knowledge, all that could be said in regard to sulphur fumigation against infectious material was that it is of doubtful efficacy, with the weight of the highest authorities in bacteriology against it. But to this it must be added that it is still largely used by very intelligent bodies in large institutions, boards of health, etc., where it would not be likely long to maintain an unearned confidence. Dr. Squibb believed that many of the recent failures with sulphur fumigation might, perhaps, be due to the fact that the fumes were applied dry, while formerly, when sulphur was burned in a closed chamber as a disinfectant, the surfaces were all wetted and the pot of burning sulphur was set in water or wet sand, that the heat might evaporate off a constant supply of watery vapor. These conditions, he said, were now frequently, if not generally, neglected, and where this was the case failure on principle should be the rule. Nearly all, if not all, chemical disinfectants are in a state of tension, ready to change on coming in contact with the matter to which they are applied, and these changes are either by oxidation or deoxidation; while the moment of greatest power or activity is the moment of change, when, by reacting on infectious matter, they pass from a state of tension to a state of rest under new relations. The agency through which these changes almost invariably become operative is the vapor of water. When sulphur is burned in a closed chamber, the dioxide is formed by condensing two molecules of oxygen from the air upon each molecule of sulphur, and the result is a heavy gas, which tends to settle at the bottom of the chamber and to run out through the lower cracks. Any moisture present is at once seized by the rather inactive anhydride, first forming sulphurous acid, and then, by oxidation from the air, sulphuric acid. It is during these changes that its power is exerted. If no moisture is supplied to the burning sulphur, that present in the air and on the surfaces of the chamber will soon be used up, and the dry gas remain in a comparatively inactive, inefficient condition. The anhydride will necessarily destroy all organisms which breathe in any degree, because breathing surfaces are moist. But in embryonic life protected by shell, as in seed, if the shell is dry, the gas will be impotent. Many bacteriologists have admitted that burning sulphur will kill bacteria, but not germs.

In commenting on this communication of Dr. Squibb, Dr. Smith said that it seemed probable that the apparent negative result of burning sulphur in the ward, as above stated, was due to the absence of moisture, since it was burned dry. In order to destroy the specific principle of diphtheria, Dr. Llewellen Eliot recommended, during the continuance of a case, the constant evaporation of turpentine over a water-bath. Dr. Smith said he had employed the following prescription for the purpose of disinfection during his attendance on cases, with apparently so good a result that he felt encouraged to continue its use:

℞.—Acid. carbolici } . . . āā f℥j.
Ol. eucalypti }
Spts. terebinth. . . . . f℥vj.—M.

Of this two tablespoonfuls are added to one quart of water, and the mixture placed in a shallow pan with broad surface. It is to be maintained in a constant state of simmering in the room occupied by the patient.

He next described the disinfection carried out some years ago by Prof. R. Ogden Doremus, in the wards of Bellevue Hospital, where pyæmia had been prevalent, by means of chlorine gas freshly set free; and then went on to say that diphtheria would continue to spread and largely increase the aggregate of deaths, unless stringent measures were employed to prevent its propagation by mild walking cases. He had, in a number of instances, seen children with diphtheria sitting among other children in the clinics at Bellevue Hospital, and had, in many instances, traced the disease directly to the schools, where one or more of the children had complained of sore throat. He saw no way to prevent its propagation by these mild cases except by enforced inspection and surveillance of children by parents, nurses, and teachers. Wherever diphtheria was at all prevalent, children who had the least sore throat should be excluded from the schools and compelled to remain at home.

In order to adopt adequate preventive measures the

fact should also be recognized that third persons who have had no diphtheritic symptoms themselves and infected apparel or furniture may be the medium of communication. After referring to several recorded instances of this kind, he said that nurses and physicians attending diphtheritic patients should avoid so far as possible the infection of their persons and clothing. Physicians in examining the fauces of children with diphtheria were very liable to receive upon their faces or clothes particles of the pseudo-membrane or infected muco-pus ejected by the violent cough excited by the examination. This might, to a considerable extent, be prevented by standing on one side during the examination, but he himself constantly carried corrosive sublimate with him, and washed his face and hair with a solution of it before leaving the apartment if he suspected that he had received any particle of the infectious material upon his person. Physicians thus exposed should also make use of precautionary measures in their subsequent visits to other children.

In conclusion, he referred to the paper read by Dr. A. Caillé before the New York Academy of Medicine in January, 1888, on the prevention of diphtheria, in which he stated that occasionally children had a recurrence of diphtheria each spring or autumn. Thinking that such children might perhaps harbor or carry with them the germ of the disease, he selected eight children having a permanent residence who had had repeated astacks of diphtheria, and subjected them to prophylactic treatment. All carious teeth were extracted or filled, and the mouth was rinsed after each meal with a solution of potassium chlorate, sodium chlorate or sodium borate. The solution was also gargled and injected or drawn through the nostrils. With this treatment the children had escaped the customary diphtheritic attacks during the two years that had elapsed since it was commenced.

CORRESPONDENCE.

THE CLINICAL APPLICATIONS OF BARIUM AND OF STROPHANTHUS.

To the Editor of THE MEDICAL NEWS,

SIR: When the defendant in a suit fails to appear, either in person or by attorney, judgment is taken by default, and great difficulty attends upon attempts to reopen the case. In the issue of this journal for February 23d ult., Prof. Bartholow has taken exception to the article of Dr. Hare, relating to the clinical applications of barium, claiming that he is entitled to some credit for its introduction and use upon this side of the Atlantic. While not necessary as a defence of the claims of Prof. Bartholow, it may be interesting to know what he taught concerning this remedy as early as the winter of 1881, and I take pleasure in reproducing from my note-book an extract of his remarks.

"The use of barium in medicine is a capital illustration of the advantages of scientific investigation as compared with empiricism. It (barium) has an acrid, styptic taste, and produces a flow of saliva and the stomach juices; in toxic doses it acts as an irritant poison. It increases the peristalsis and acts upon the nervous system; it slows the heart and its contractile power is largely increased. This is effected by the stimulation of the vaso-motor nerves, but when too long continued it may cause rigidity and tetanus, followed by paralysis. The pupil is dilated, this being due to stimulation of the radiating fibres of the iris.

"Therapeutics: It was first considered to be an alterative, but does not belong in this category. It has been used in aneurism, with or without Tufnel's method, and as it acts more energetically than ergot, it can be employed in arresting active hemorrhage, in the early stages of inflammation (the stage of congestion), in paresis of the bladder and in weak heart."

Like Prof. Bartholow, I feel that my efforts relating to strophanthus and its clinical applications have been overlooked in the course of your editorial in the same number. If you will refer to the issue of this journal for February 4, 1888, it will appear that I have already filed a caveat in the following words: "And I venture the prediction that its (strophanthus) value as a therapeutic agent will be greatly extended when it becomes more generally known." Admitting the high standing and great reputation of those to whom you refer, I am not willing that it should be understood that all of our knowledge of the clinical application of drugs comes from abroad. My prediction was based upon the results of clinical observation, and the experience of others, as well as my own work, goes to show that the favorable opinion was fully warranted.

Within the past year numerous references have appeared from time to time in THE MEDICAL NEWS, but for the most part, the authors have been foreigners, a fact which is not to the discredit of the remedy nor the writers, but it implies a lack of that spirit of investigation, which is so characteristic of our American people, and fails to do them justice. Neither the physicians nor the surgeons of this country are behind their trans-Atlantic brethren in enterprise, but the opportunities here for investigation are less numerous, and as a result, the work that demands attention on the spur of the moment is often marked by evidences of haste. Time will remedy these defects, and show that American citizens are entitled to take the lead in every department of medicine and surgery, and the references in our journals to foreign authors will be the exception rather than, as now, the rule.

JOHN AULDE, M.D.

PHILADELPHIA, March 23, 1889.

[The editorial to which our correspondent takes exception explicitly stated that it only referred to discussions which had taken place in the medical societies "within the *past few weeks*," and, therefore, his observations, which were published a whole year before, were of course not included.—ED.]

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia*

VOL. LIV. SATURDAY, APRIL 6, 1889. NO. 14.

ORIGINAL LECTURES.

THE TREATMENT OF BLEEDING FIBROID TUMORS OF THE UTERUS.

A Clinical Lecture Delivered at the Hospital of the Philadelphia Polyclinic and College for Graduates in Medicine.

BY B. F. BAER, M.D.,
PROFESSOR OF GYNECOLOGY.

GENTLEMEN: This patient first consulted us in November, 1887. She is thirty-five years of age, and has been a widow seven years. She has never been pregnant. The prominent symptoms in the case were uterine hemorrhage, recurring every three weeks, and lasting eight to ten days, with a watery fetid discharge in the intervals, and such loss of strength as to compel her to discontinue her daily occupation. These symptoms might lead you to suspect carcinoma of the uterus. The character of the hemorrhage, however, was not that which usually attends cancer of the womb, for in the latter case the hemorrhage is irregular, coming on at any time during the month, usually as a result of necrosis of tissue, and rarely observing the periodical character which is common to hemorrhages the result of other diseases of the uterus or ovaries. The hemorrhage in this case was periodical and corresponded in time, probably, to the period of ovulation, although when once started it was difficult to control, because the uterus had lost its usual power to contract and check the flow, as is the case when that organ performs its functions naturally.

When metrorrhagia is great and painless it is more likely to be the result of fibroid tumor than of any other condition. As a rule, however, fibroid tumor does not result in emaciation; the patient often presents a healthy, rotund appearance. But this case is an exception to the rule. This woman was so reduced from the suffering and hemorrhage that she was a confirmed invalid. The suffering resulted from the position of the tumor. If the tumor is not of great size and occupies a position where pressure will not interfere with the function of contiguous organs, the bladder and rectum, very little inconvenience is felt from its presence, and if hemorrhage is not severe, the patient may go through life unconscious even that she has a tumor, or at least in such comfort that she may never consult a physician. But where the tumor occupies a position as in this case (within the pelvis largely), it may give rise to the greatest suffering.

Examination showed the cervix elevated, and the entire womb crowded forward and to the right, by a tumor which occupied the left side of the pelvis. It seemed to be connected with the left side of the womb. There was also in the right iliac region a tumor, solid and firm, which seemed to be closely connected with the womb also. When these tumors were moved the uterus moved with them, and there was still another posterior to the uterus. Now, when the womb moves with the tumor, I think it is well to infer that the case is one of uterine tumor, and, therefore, fibroid. But this is not always the case. An intraligamentary cyst may have such close relationship with the womb that the latter organ will move with the movement of the tumor; or an ordinary pedunculated ovarian tumor may, by an inflammatory agglutination, give rise to such adhesion to the uterus as to cause that organ to move when the tumor is moved. Inflammatory disease of the Fallopian tube and ovary, together with pelvic peritonitis, may give rise to a tumor, movement of which would cause the womb to move also. There are other characteristics, however, of these latter tumors, which will nearly always serve to differentiate them from fibroids. For instance, in this case the tumor is hard and nodular, the nodules being round and smooth, a condition which is seldom found in any but fibroid growths. Then the time of the existence of the symptoms is important. Fibroid tumor is of slow growth usually.

A diagnosis of fibroid tumor was made in this case, and as surgical measures were rejected by the patient, she was ordered ten grains of chloride of ammonium three times a day, together with the fluid extract of ergot and the tincture of nux vomica, of each twenty drops three times a day. She was advised to see us from time to time. She has been taking this medicine regularly for a number of months with the greatest benefit, symptomatically, although with very little improvement so far as the decrease in the size of the tumor itself is concerned. She reports that she at once began to improve; that within a month after she began to take the medicine the hemorrhage was less severe, that the pain and other symptoms diminished. She has long since resumed her occupation, and is comparatively comfortable. She has gained in flesh, and is in every way in a much improved condition.

On examination to-day, more than a year after the treatment was begun, I find the tumors more mobile, but I cannot say that they are much smaller than they were at the first examination. There certainly has, however, been a modification in the circulation, and probably, therefore, in the nutrition of the growths, or there would not have been such marked improvement in the general condition of the patient. The only medicine she has taken in addition to the chloride of ammonium, ergot, and nux vomica, has been a laxative pill.

The result of the medical treatment, at this time, would seem to teach the lesson that the patient was right in rejecting the operation—oöphorectomy—which I advised more than a year ago. But time must decide.

The next case will serve further to illustrate the management of cases of fibroid tumor where grave surgical measures—oöphorectomy or hysterectomy—are declined by the patient or are not considered proper by the surgeon. The patient has been under treatment about four months. She is forty-six years of age. She has had

two children after normal labors, the youngest being seventeen years of age. She ceased bearing children at twenty-nine, and therefore may be regarded as a case of acquired sterility. Five years ago she began to lose more at her monthly periods than the normal amount, and this had increased, so that at times it would amount to what she characterized as a flooding. She complained of considerable soreness in the left ovarian region, and sometimes sharp cutting pains shooting down the thigh. There was also considerable pressure in the pelvic region, and sometimes irritation of the bladder from pressure. She was at the age at which the menopause usually occurs.

You are, doubtless, familar with the erroneous popular belief that flooding at this period of life is physiological. But this woman is not bleeding because she is forty-six years of age. The fact that metrorrhagia at this age is as likely to be the result of disease of the uterus or its appendages as it is at any other time, should not be forgotten. We found here an abundant cause for the hemorrhage, as will be found on investigation in almost every case of bleeding at this time of life. As thorough investigation should be made at forty-five as if the patient were thirty or thirty-five years of age. The hemorrhage should be looked upon as pathological. In my experience there is no such thing as physiological metrorrhagia, and I believe so to regard it invariably results in harm, because the fears of the physician, as well as those of the patient are quieted by such belief, until what might have been a curable disease, if recognized in its incipiency, has advanced to a stage where even palliation is scarcely possible before relief is sought. This is especially true of cancer, but practically applies to all cases.

Investigation proves that in those women in whom the cessation is gradual, and without more than the ordinary menstrual flow, better health is enjoyed then and afterward than where the so-called critical floodings occur. Where health exists the cessation of menstruation will be attended by no more aberrations of function than are seen in its establishment. Where deviations from the normal standard are marked and persistent, they should be regarded as pathological, and the cause sought for.

Examination of this patient, when she first came under our care, revealed a firm, hard mass just above the anterior wall of the vagina, the position usually occupied by an anteflexed uterus. As the finger was advanced along the under surface of this mass it was found to be continuous with the cervix. The latter organ was considerably enlarged, and the os so patulous as to admit the index finger far within its cavity. The mucous membrane was soft and hypertrophied. The hypogastrium was enlarged by several irregular tumors. They seemed to be one with, or closely attached to a common centre, which resembled the uterus, the whole forming a mass which filled the pelvis and the lower portion of the abdomen. The tumors were firm, and smooth on the surface; there was not the slightest evidence of fluctuation. These are characteristics of fibroid tumor, and because more than one was present a diagnosis of multiple fibroid tumor of the uterus was made. Two of the tumors were sub-peritoneal in character, but closely attached to the womb, rather sessile, rendering that organ soft from congestion; hence the hemorrhage. Of course, you are aware that the immediate source of the hemorrhage does not proceed from the tumor itself, but from the endometrium. Where a fibroid tumor exists there is always a secondary irritation of the lining membrane of the womb, and the nearer the tumor is to the uterine cavity the greater this congestion and hypertrophy, and therefore the greater the hemorrhage. In cases of this character, to locate the exact position of the womb, and to get a correct idea as to its size and the condition of its cavity, it is necessary to introduce the uterine sound. The sound gave a measurement of four inches, and showed a rugous, irregular condition of the lining membrane, and indicated that the main symptom in this case—the hemorrhage—might be greatly modified, and probably entirely relieved by treatment directed to the uterine cavity.

It would not have been proper to advise radical treatment by laparotomy in this case. First, because the patient was at an age when we would naturally look for a cessation of ovulation and menstruation, and therefore oöpherectomy for the purpose of bringing about the menopause was uncalled for. Hysterectomy was contra-indicated for the same reason. Even if the patient had been thirty-six instead of forty-six years of age it would not have been proper to subject her to a dangerous radical operation when we had such simple means of treatment as the course which was successfully pursued in this case.

The patient was placed in bed, and the bowels regulated by a gentle laxative, and antiseptic vaginal douches were made use of for the first twenty-four hours. A tupelo tent was then introduced and permitted to remain until the next day, when it was removed and irrigation with the bichloride solution made, and three tupelo tents introduced. These so thoroughly dilated the canal and softened the tissues that I was enabled to pass my finger to the fundus. I found that the mucous membrane was, as had been anticipated, greatly hypertrophied, but there was no polypus present. Curretting was then thoroughly made, and a large quantity of this degenerated mucous membrane removed, one piece half as large as my thumb coming away *en masse*. This mass was located at the left cornu. The parts were then thoroughly irrigated, and afterward a solution of iodine and carbolic acid injected into the cavity. The operation was done without the administration of ether, so slight was the suffering. She was then ordered ergot and nux vomica as follows:

℞.—Tr. nucis vomicæ }
Ext. ergotæ fluidi } . . āā f ℥j.—M.

Sig.—Forty drops in water after each meal.

In addition, she took ten grains of ammonium chloride t. d.

She remained in bed a week after this, and was then permitted to go about. She has taken the medicine regularly since that time. The uterine cavity has also been medicated about every second week by the injection of the iodine and carbolic acid mixture with which you are familiar.

The patient states to-day that she has been free from hemorrhage or other discharge for two months, and that the pain has entirely disappeared. On examination I find a marked improvement in her condition. The os uteri is not widely open as it was; the uterus and the tumors are more firm, there is greater mobility, and there

is not the evidence of congestion which existed when she first came under treatment. The patient is symptomatically cured. True, she still has the tumors, but as fibroid tumor is a self-limited disease—that is, depends for its growth upon ovulation—as soon as the latter function has disappeared, the tumors will undergo atrophy in accordance with their natural history.

She will continue taking the ergot and nux vomica, and the chloride of ammonium; the former to induce contraction in the bloodvessels, so as still further to cut off blood supply; the latter as an alterative. We will also continue the medication of the endometrium every two weeks until it shall appear to be in a healthy state. I think I am safe in saying that we have practically cured this woman by a comparatively mild and safe operation.

The next case (pedunculated sub-peritoneal fibroid tumor, incarcerated in the pelvis; complicated by peritonitis; removed by laparotomy) forcibly illustrates the danger of permitting a fibroid tumor to remain incarcerated in the pelvis. The patient is thirty-nine years of age, has been married ten years, and is sterile. She has suffered from dysmenorrhea since puberty, and during the last five or six years has had frequent attacks of pelvic peritonitis. She first presented herself six months ago, complaining of the following symptoms: Great pain in the left ovarian region, and a sensation as though something were wedged in the pelvis and pressing upon the urethra. She had not voided her urine spontaneously for months, having been taught to use the catheter.

Examination showed the cervix uteri low down near the vaginal orifice, the body of the womb anteflexed and crowded against the right side of the pelvis by a tumor, which occupied the left side of the pelvis and extended above the superior strait. The tumor was firm, somewhat nodular, and excessively tender on pressure. There has evidently been an exudation of lymph and a diagnosis of incarcerated fibroid tumor complicated by pelvic peritonitis was made.

The suffering of this patient was so great, and the tumor so firmly fixed that I at once advised the patient to undergo laparotomy for its removal. It would have been exceedingly dangerous to force this tumor out of the pelvis into the abdominal cavity, because of the exudation of lymph which surrounded it, and of the possible presence of pus. The patient was considerably emaciated from the suffering. She was ready and quite willing to undergo any operation which would offer a hope of relief.

Laparotomy was performed four months ago, an incision three inches in length being made in the hypogastrium. When two fingers were introduced, it was found that the omentum and intestines were glued firmly to the pelvic organs and upper surface of the tumor. After carefully dissecting among the friable lymph I came upon a tumor so deeply seated in the pelvis that it was difficult to reach it, and it was with great difficulty that I finally succeeded in elevating the tumor sufficiently to sever the pedicle; but, by coaxing and persistence, I finally succeeded. After the tumor was separated, the pelvic and abdominal cavities were irrigated with warm, previously boiled, water, a drainage tube inserted, and the wound closed around it.

The patient recovered without an untoward symptom, and she has been entirely free from pain since the operation. She has resumed her domestic duties, and states that she is in better health than she has been for years. I did not remove the ovaries in this case, as they were not found, and I did not feel justified in prolonging the operation to seek for them. If the attachment of the tumor had been sessile, I would have been compelled to remove the womb with it; but as it had a short, well-defined pedicle, I was able to separate it from the womb, and as the symptoms were due to the impacted tumor the indications were fulfilled by its removal.

The three cases which I have presented serve to illustrate a method of treatment successful in each, as well as the extremes of treatment which may be required in the management of cases of fibroid tumor. In the first case the treatment was entirely non-operative, and succeeded in relieving the patient. In the second, a minor operation likewise succeeded in relieving the symptoms and practically curing the patient; while the last case required a radical and major operation to effect a cure.

A PLEA FOR THE USE OF THE MANGANESE COMPOUNDS IN CERTAIN FORMS OF DYSMENORRHŒA.[1]

By C. O'DONOVAN, Jr., M.D.,
of Baltimore.

At a meeting of the Gynecological and Obstetrical Society of Baltimore, held December 13, 1887, I presented a paper entitled "Remarks on the Use of the Manganese Compounds in Menstrual Disorders," in which I reviewed the literature of the subject up to that date, and expressed the opinion that in these drugs we have satisfactory remedies for certain disorders of menstruation. Considering the importance of the subject, when we remember the comparative infrequency of normal menstruation amongst our modern women of the cities, I was surprised at the meagreness of its literature, the number of references being few, and the articles referred to often proving to be records of isolated cases, or of groups of five or six only. The strong commendation of Drs. Ringer and Murrell in England, and the testimony of Dr. Fordyce Barker of New York, and of Dr. Martin of Chicago, atone, however, for what is lacking in others.

As the subject is one of therapeutics, and treats of a class of cases that necessarily appeals to the general practitioner and family physician before resorting for relief to the gynecologist, I thought it appropriate to present this paper rather to this Society than to any other, as more likely thus to reach those for the amelioration of whose sufferings it is intended. To every one of you has come at some time, or will certainly come, the mother of some young girl with a pitiful story of her daughter's sufferings at every menstrual epoch, perhaps as the result of exposure at that dangerous time to cold or wet; or, perhaps,

[1] Read before the Clinical Society of Maryland, February, 1889.
[2] See Maryland Medical Journal, January 7, 1888.

she will state that there has always been some discomfort attending menstruation, which has increased month by month until now she is worn out with suffering and unable longer to bear the tax upon her nervous system; or there may be amenorrhœa, from suppression of menses, either as a result of cold or from some other cause to be discovered by you, and remedied; but in every case it is the disordered menstruation that is causing most anxiety, and it is that which demands consideration.

The question put to you is plain; how will you answer it? The busy practitioner has little time for listening to the innumerable complaints of nervous girls and is apt to put such a one off with a placebo, hoping to gain time; or, if he feels especially interested in the patient, he builds her up on a long course of iron, with the bitter tonics, listening patiently to her many woes, quieting her nerves with anodynes, and hoping for a cure after a time; sometimes he succeeds fairly well, oftener he fails, and again returns to the point from which he started; though benefited for a time, his patient is again languid, nerveless, leading a life of terrified expectancy between her menstrual epochs, undergoing tortures with each recurring period. In an unguarded moment he suggests a vaginal examination by some gynecologist in consultation, only to find mother and daughter in arms against any such treatment, and most likely deeply insulted at the bare suggestion; the usefulness of that practitioner in that particular case is gone forever, he has confessed his inability to treat the case, and all confidence in him is lost. Very often he will hear within a month that the consultant whom he happened to suggest, is in charge of the case as trusted attendant.

It is well to state just here that all cases of dysmenorrhœa are not due to misplacements of the womb, or to any anatomical irregularities that can be discovered either by gross or microscopical examination, and many times have excellent diagnosticians been wrong in making diagnoses from the symptoms, which seemed to point so clearly in one direction, but which had led to a fallacious conclusion.

In order to call attention to another, and a very potent drug for good in many instances, I wish to relate some of my experiences with the manganese compounds in cases of this sort; and if the reader will carefully follow me, I am sure that he will often be spared the mortification of failure, and his patients will escape much suffering. I speak now more particularly of unmarried women, who naturally rebel against physical examination, and whose sensibilities should be respected as far as possible. With married women it is different, and, rather than waste time upon a trial of drugs, I think it better to make a vaginal examination as soon as the symptoms point unmistakably to uterine or ovarian disease, when we obtain data for a diagnosis quickly and certainly, and may institute treatment founded upon knowledge rather than upon theory. That manganese is beneficial often to women who are married and sterile, and in certain states to those who have borne children, I shall prove further on; at present I speak only of those who are unmarried.

Case III.—A. M., white, æt. twenty-four, unmarried, consulted me for the first time for this trouble, January 18, 1888. She was a tall girl, rather thin, but well-developed; arms, hips, and breast of perfect form and symmetry; her general health between menstrual epochs was fair, her appetite being capricious; her bowels were never regular, varying between constipation, the usual habit, and slight attacks of diarrhœa; she was pale, suffered from cold hands and feet, with a well-marked development of neurasthenia, probably due to her work, which was clerical, and imposed a severe strain upon her both physically and mentally. There was nothing organically wrong with her heart or lungs, but any slight cold would last with her for a long time, and over-exertion often produced what she called "palpitation of the heart" in paroxysms, though I never witnessed one.

Whenever she menstruated her sufferings were intense, beginning with a sense of discomfort a couple of days before the flow, and gradually developing until the first two days of menstruation, during which she suffered tortures. When I saw her she had just passed a period, having had a worse experience than ever before, being able to bear the pain only after stupefying herself with brandy, to which she has often before been compelled to resort on similar occasions, but which she would never touch under other circumstances. At that time I thought that her dysmenorrhœa was due to anæmia, so I accordingly directed her to take medicine to keep her bowels regular, and ordered iron in small doses (Blancard's pills) with each meal. Under this treatment she grew stronger, her appetite improved, and she was better able to stand the worry at her office. Everything went well until the return of her menstruation, when she passed through the same miserable experience as before. I persisted in the treatment, varying it in detail by substituting other preparations of iron, but with no better success at her menstruation during March. At that time I was using permanganate of potash, so, on April 3d, I ordered one grain of this salt, to be taken three hours after each meal, with half a tumblerful of water or milk. She tried the remedy faithfully, but reported that it disagreed with her stomach constantly, notwithstanding the use of larger quantities of water, so, on April 18th, I ordered, instead, one grain of the black oxide of manganese, to be taken in the same way.

May 3d, she reported that she had had the most satisfactory period that she could remember; the flow was ample and she had had very little pain, so little that instead of lying at home drugged with brandy, she was able to attend to her regular work. After this she was instructed to begin with the manganese oxide a week before each returning period, and take three doses each day until she ceased menstruating; this she has done with more or less regularity ever

since, and she has always had comfortable periods if she takes the drug, but if she neglects it, she is always reminded of her neglect by a recurrence of her dysmenorrhœa.

I relate this case as a type, representing cases that may occur every day in the practice of anyone; she represents the poisoned air of the large office crowded with desks, at which women sit every day wearing out their vitality, and becoming more and more habituated to suffering and disease. Had she been weakest in the lungs, most likely she would have developed consumption, but as her nervous system was least able to bear the strain, it was neuralgia that developed most prominently, directed chiefly toward the menstrual function by the probable existence of some abnormal development of the uterus, or perhaps by some unknown ovarian influence. It is in this class that often appears hystero-epilepsy, and my patient was bordering upon that state, if I may believe her statement of twitchings and involuntary jerkings of her muscles while she suffered so intensely; that disease which is so little understood, and is treated so variously. Had she continued as the course of her sickness ran before I saw her, growing worse all the time, each succeeding period bringing her nervous condition into more and more abnormal prominence, as she depended upon her daily work for support, it would soon have become an open question with many gynecologists whether or not her ovaries should be removed. Yet under treatment such as I have indicated, she has recovered, and is able to look forward to a life of comfort, freed from the constant dread of each period that formerly rendered her miserable. She is still pale, is still taking iron occasionally, and must be very careful in her diet unless she would fall back into her old habit of constipation; she is still nervous at times, and often feels as much fatigue from overwork as she formerly did; the change for the better in her menstrual sufferings cannot be ascribed to any change in her general condition, for there is very little change, but as long as she takes the manganese regularly she is free from that suffering, and as surely as she neglects it, it returns. The conclusion seems very clear, that in some way she is benefited by the manganese.

Were this an isolated case, I should not dwell upon it so, but I have records of a number of similar cases, of whom many were benefited nearly as much, some quite as much; some whom I had classed in this category, failed to receive relief, of whom several consented to a vaginal examination, and in every instance sufficiently acute flexions, usually anteflexion, were found to account for the failure of the treatment. Under no circumstances would I propose an examination to an unmarried woman presenting the symptoms detailed in this case until I had for three months failed to relieve her during treatment with manganese; this length of time I should consider enough, though some authorities report satisfactory results after six months of continuous use.

Case XIV.—E. M., white, æt. twenty-four, unmarried, consulted me April 12 1888. She was under the medium height, but well developed, having firm muscles and a well-rounded form. She was engaged every day as a saleswoman in a store, and was compelled to be on her feet nearly all the time. She lived about two miles from the store, and usually walked both ways each day; she was of a lively disposition, full of spirits, vivacious and entertaining; she presented no appearance of ill-health whatever, had a good color and bright eye, but would lace her corsets so tightly that her waist was a marvel. She complained of intense and increasing dysmenorrhœa, which had begun about three years before her visit, and had been growing worse with each successive menstrual epoch, which recurred regularly, lasted four days usually, but with a scanty flow. The pains were always worse just before the commencement of the flow and during the first two days of menstruation, becoming easier then but not disappearing entirely. She had never taken any care of herself, would expose herself to wet and cold during her periods without any extra precaution, never gave up any pleasures that might interfere with her health, and was experiencing the natural consequence. She had never had any treatment for this trouble. Otherwise she was in perfect health, her appetite was good, her bowels somewhat constipated. I ordered for her one grain of the black oxide of manganese twice a day, in the usual manner. May 8th, she reported that she had taken the capsules regularly as directed, and had passed through a period without discomfort, much to her surprise, an experience to which she had been a stranger for three years. The flow came on without any warning, lasted the usual time, was somewhat more profuse than usual, and was accompanied by no pain. May 22d, she called at my office, and stated that she was then menstruating, that she had been working all day at the store, and felt only a slight ache in the back. She asked if I thought it would hurt her to go to a church fair that night, telling me that she meant to go whether I approved or forbade her. This was evidence enough for me that she was not suffering very much.

This case represents that class of patients who, having been born of healthy and vigorous parents, start well in life, gifted with all the physical qualities necessary for growth, and who advance satisfactorily until puberty, giving promise of perfect womanhood, but for some reason or other, while in perfect health externally, the establishment of the menstrual function is accompanied by more or less inconvenience and pain, which condition instead of diminishing after the regular appearance of the menses, becomes rather more aggravated at each successive period. As the girl is in such health apparently, she is called upon to do her share of work in supporting the household, and her sufferings are treated as imaginary, or are laughed at, by those whose ignorance is

alone an excuse for their conduct. If her mother should have sense enough to consult a physician, the chances are that she will be told that her daughter will eventually outgrow her trouble, or some other equally evasive answer will be given her. The poor child knows the reality of her sufferings, but finds that all her natural protectors and guides unite in making little of them, so she is compelled to bear as best she can what might have been, in many cases, easily relieved, and the habit of dysmenorrhœa gains a deeper hold on her system with each succeeding period. Then comes the time of work, and association with other girls, many of whom are suffering from the same malady, from whom she learns the use of whiskey or morphia to deaden the pain which has grown too severe to be endured, remedies which are used at first to relieve only the agonies of dysmenorrhœa, but after a while are called upon to relieve every pain or ache, real or imaginary, to which her diseased nerves call attention, until the habit becomes too firmly fixed to be discontinued. Cases illustrating the truth of this story will occur to too many of us.

Had these girls been properly treated at first, had their complaints been patiently heard and suitable medicine been given them, many would have escaped that are now victims of these habits. I do not claim that manganese will relieve every girl whose history is such as I have detailed, but I would have every physician acquainted with its virtues, and prepared to use it in all properly selected cases.

CASE XIX.—J. M., white, æt. twenty-seven, unmarried, consulted me for the first time on May 17, 1888. She was a tall, well-developed woman, of splendid physique and fine carriage, a blonde, with a clear complexion and a fair amount of color; a good walker, given to no habits of sedentary laziness, but full of energy and activity. She said that at each period since the establishment of menstruation she had suffered from intense pain just before the appearance of the flow and during the first day; for relief she was always obliged to remain in bed, where she bore the pain as patiently as she could, with the assistance of unlimited quantities of gin, thinking that the pain was a necessary accompaniment of menstruation in her case, and had ceased to hope for relief, as she had been treated by several physicians at different times with various medicines, but with equally bad results. Her description led me to conclude that she had an anteflexion of the cervix, and I suggested the trial of manganese with very faint hopes of success. It was ordered in one-grain doses thrice daily, to be taken in the usual way.

June 7. She reported that she had taken the manganese regularly, and had just passed through the most satisfactory menstruation that she could recall. She was ordered to take the capsules three times each day for a week before her next period. After this I did not see her again until December 10, 1888, when she told me that for three months she continued to use the capsules as I had directed, and that each time she experienced perfect comfort, her menstruation being regular and painless. Through some misfortune she had then lost the prescription, and being out of the city she had been unable to have it repeated; since she ceased to take the manganese, her old trouble had returned, and she had again the dysmenorrhœa as severely as ever, so that she was again compelled to spend a day in bed at each period. I ordered the same treatment, and on January 11, 1889, she reported that she had just passed through a period that gave her no trouble whatever.

This example is drawn from a higher social grade than the former two, and represents those women who grow up in pampered idleness, whose nervous systems have been developed in the unhealthy atmosphere of the crowded schoolroom, where the greatest attention is paid to the education of the brain, and little care is given to the body. As soon as the school is left comes the constant whirl of social amusements, engagements of one kind or another which fill up the afternoon and evening, seldom allowing the participant to have any sleep before midnight, and too often keeping her from rest until two or three in the morning; taking her night after night into crowded rooms, where the temperature registers from 90° to 100°, and every cubic foot of air is respired again and again until it becomes disgusting to one newly entering from outside. From this she goes suddenly out into the freezing atmosphere of a carriage, while she is still overheated and insufficiently clad for the change; and then to bed, where she tosses restlessly, vainly trying to banish from her excited brain the constantly recurring scenes through which she has been passing. Is it any wonder that the modern society woman, before she reaches twenty, begins to be pale, to grow thin, to complain of her nerves, and to seek remedies for sleeplessness and other ailments?

Fortunately, the lady whose history I have related did not indulge in these social dissipations immoderately, and had too much sense to be blindly controlled by all of fashion's follies; she would not pinch her feet into narrow shoes with high heels that would throw her so far forward that she could maintain her erect posture only by overtaxing her lumbar muscles; she would never so constrict her waist with corsets, as many do, that all the pelvic organs would be crushed together, with the uterus very likely thrown so far into the hollow of the sacrum that, after a time, the ligaments would not retain it in its proper place; she would not give way to that laziness that usually goes with social indulgence, but kept her bodily health far above the average by plenty of exercise out of doors, and by a careful attention to all the rules of hygiene as applied to the human body. Had she indulged in these faults, I feel certain that she would have been in far worse condition, and

doubt much if my treatment would have relieved her so promptly and effectually. Yet, as the representative of the class of the highly organized society woman of the day, she will bear evidence to the efficacy of manganese in relieving the character of menstrual disorder so prevalent in her class.

For less pain than she suffered, I have no doubt that many women have submitted to the operation of posterior section, and a greater number to mechanical dilatation of the uterine canal—operations which render necessary an unknown amount of after-treatment to prevent the subsequent closure of the canal. If we can avoid the necessity of these operations by the employment of manganese, even in a small proportion of the cases applying for relief, we must admit the value of the remedy. And it is just in this class that the best results may be reasonably expected from its use, for I am led to consider it a tonic peculiarly adapting itself to the organs of generation; whether through direct action upon the organs themselves, or by means of their nervous supply derived from spinal centres, is as yet unknown, but its action is to be expected most surely in women who are deficient in tone of muscle and nerve from those causes to which our modern society woman is exposed constantly, and which is variously described by those subject to it as languor, depression, sense of weakness and inability to do anything, and which is often particularized as backache with no definite limit, as a sense of weight in the pelvis with a weakness of the lumbar spine, and in many other ways as numerous almost as the individual sufferers. In many of these cases manganese is the tonic required; many cases are on record that prove its effect for good; I have records of several.

Another class is represented by

Case XV.—I. A., white, unmarried, æt. thirty-five; who consulted me for the first time on April 19, 1888. She told me that she depended upon her sewing for a living, much of it being done with a heavy sewing-machine, after which work she always felt much worse; the aching, and sometimes even intense pain, were in her back and hips, and extended, when it was particularly bad, up along her spine on both sides. With each recurrence of menstruation she suffered with severe dysmenorrhœa, which persisted throughout the period, and left her completely fagged out. In addition she was dyspeptic, nervous, constipated, and sleepless, suffering from that train of symptoms found so often in sewing-women. I ordered nothing but manganese oxide in one grain doses, to be taken twice daily, and an aperient to be used when required. April 26th she reported that her back felt much better and that her nervousness seemed more under control. May 8th, she had passed through a menstrual period since I saw her last, and suffered only slight inconvenience. She felt like a different person, had no backache at all, and was able to work much better and for a longer time at a stretch than for years. She felt that she could not get on at all without the manganese. I have heard since from her, and the improvement continues, though she does not take the medicine so frequently, but has recourse to it if she finds that her health is again deteriorating.

The success of the treatment in this case teaches that age offers no bar to the use of manganese, nor should the length of time that dysmenorrhœa has persisted cause us to despair of relieving it. If the habit of pain can be formed, we should naturally suppose that it had fully developed by the age of thirty-five, especially when it had been augmented and intensified by hard work and sedentary habits, such as go always together in the case of seamstresses. If these good results may be expected in such cases, we see at once a wide field of usefulness in this one direction, for every woman who follows closely this mode of life becomes more or less affected in a similar manner, especially unmarried women, of whom we are now speaking particularly. I can recall very few who sew, and who, having reached the age of thirty, can claim immunity from pain during menstruation; amongst those who use sewing-machines I can remember none; those who, during the early years of menstrual life, had suffered little or no discomfort, have gradually developed dysmenorrhœa; those who had always more or less pain, have had it intensified, and in each class the process of increase continues with each period.

Now, the causes of this are various; there may be malposition of the uterus, which probably causes the greatest number to suffer; there may be cellulitis, either acute or chronic, as it is so likely to become in women so situated that they are unable to have the rest and treatment necessary to cure it, and this cause probably ranks second in frequency; there may be a prolapsed ovary, either free in the cul-de-sac, or bound in its false position by adhesions, and causing most intense and persistent suffering; in none of these cases can we expect much relief from manganese, for the cause of the trouble is irremediable by medical treatment alone; but, apart from these, there are many women whose constant labor has so worn them out, so broken down their nervous systems that, unassisted by the peculiar influence of some medicine having special power in such cases, they must give up, or go on in an agony of suffering. Do we know of any drug that can exert such power? In cases properly selected I have seen manganese act just in this way, and in proof I have related the foregoing case, which is one from several of whose history I have notes. They were not all benefited as much as she was, nor so promptly, although some were, yet the improvement manifested was such as to encourage a further trial of the manganese, and with time its effect became more decided. Those cases that gave no result after a prolonged course of treatment were supposed to be

suffering from one or other of the causes detailed above, and the truth of this supposition was substantiated in a few cases by vaginal examination, but most of them declined further treatment.

In married women the use of manganese is somewhat limited for obvious reasons, for in them those objections to vaginal examination do not exist, and any discernible cause of dysmenorrhœa may readily be discovered, and proper treatment be instituted without loss of time. I have used it in cases of dysmenorrhœa, associated with sterility, whose pelvic organs were, as far as I could make out, perfectly normal, and have at times obtained benefit, but I had always before me the fear that conception might take place and an abortion result, so that in these cases the drug had never the full and satisfactory trial that it deserved; still, in cases that presented the symptoms that I have detailed previously, even in married women, I would give manganese, at least, a trial, if a vaginal examination indicated no cause of the pain; such cases would occur in those women who had suffered from dysmenorrhœa before marriage, and in whom an infertile wedlock had not only failed to relieve but had rather given rise to an increase of menstrual pain, but I should be very cautious about holding out promises of relief or of permanent cure.

When I began this method of treatment I tried first the permanganate of potash, in one grain doses well diluted with milk or water, fully two or three ounces being taken just after swallowing the pill, and more fluid was drunk if any inconvenience manifested itself in the stomach. Many of my patients took the pills readily, but some complained, saying that the discomfort persisted in spite of frequent draughts of water; so I began then to use the black oxide of manganese, and with equally good results, and without the disagreeable symptoms induced by the permanganate.

I order the drug by itself, to be put up in capsules, one grain in each capsule, and have yet to hear the first complaint from it. The dose that is usually employed is one grain three times each day, to be taken three hours after each meal, and followed immediately by at least half a glassful of water or milk. I have given doses of two, in a very few instances of three, grains, but I prefer to use the dose of one grain and continue the drug for a longer time, as the system seems to adapt itself to the remedy better, and there need be no fear of disordering the stomach. Another preparation, which I find preferred by some patients, is the compressed tablet of the pure drug manufactured by Wyeth, of Philadelphia, and other druggists.

The following conclusions may properly be deduced from the foregoing remarks:

1. The manganese compounds are valuable additions to the therapeutics of dysmenorrhœa, from which, in a certain number of properly selected cases, great benefit may be expected.

2. Their use does not interfere in any manner whatever with the administration of iron or the vegetable tonics, but rather aids and is aided by them.

3. The best results from the use of these remedies may not be obtained at once, and failure should not be confessed until after a continuous trial lasting for three months.

4. So far as we know at present, the black oxide of manganese is the most convenient form of administering these drugs.

311 W. MONUMENT ST., January 28, 1889.

THE EFFICACY OF THE OLDER METHODS OF TREATING NASAL DISEASE CONTRASTED WITH THOSE OF TO-DAY.[1]

BY CLARENCE C. RICE, M.D.,
OF NEW YORK.

IT is of historical interest only to look back twenty years and examine the therapeutic measures then employed in the treatment of nasal disease. A review of the scientific study of diseases of the upper air-passages carries us back only about thirty years —for the laryngeal mirror and suitable apparatus for illuminating the larynx and nasal cavities came into use no further back than 1858. We can obtain for our present purpose sufficiently striking comparisons by reviewing the therapeutic measures which have been employed during the past ten years.

Prior to 1860 it is the old story of earnest and diligent workers endeavoring to obtain correct ideas of the pathology and etiology of diseases, the physical appearances of which they could not see, and trying to treat mucous surfaces which were inaccessible by reason of lack of proper methods of examination. The progress made in the treatment of nasal disease during the period from 1860 to 1875 seems to us, as we look back, far less rapid and satisfactory than it has been during the past ten years. But this time was not wasted. It requires ten years in any special line of medical investigation to perfect instruments for thorough physical diagnosis and to become expert in their use. Ten years are easily spent in investigating the action of drugs when applied to mucous membranes, in discarding the worthless ones from our materia medica, and in retaining perhaps the only one of many which has not proved disappointing in its action.

In the period from 1870 to 1880, which may be properly designated *the period of topical medication* by means of douche, sprays, brush, and applicators, the disease commonly known as chronic nasal

[1] Read at the meeting of the New York State Medical Society, February 5, 1889.

catarrh largely engrossed the attention of rhinologists. The pathology and etiology of catarrhal inflammation of the nasal mucous membrane were accepted without question to be identical with those of all other mucous surfaces of the body. Nasal catarrh seemed to be a disorder the principal phenomena of which were swelling and hypersecretion; and it was the chief aim of the operator to check this apparent increase in the mucous discharge by the same methods as had always been employed in controlling hypersecretion of other mucous surfaces, and astringents vegetable and mineral were applied in all varieties of ways to the nasal surface, first with probang and brush. That the troublesome symptom hypersecretion, was not remedied by these measures seemed to be readily explained by the fact that the astringent drugs thus applied only came in contact with the lower chambers of the nose, while the upper portion, being inaccessible, were unsatisfactorily treated. It was felt that a long step was made forward when the air-pump, air receiver, and atomizing tubes were at last perfected, and all portions of the nasal and pharyngeal mucous membrane, even the most remote, could be medicated by their use.

It required ten years to demonstrate that these phenomena of catarrhal inflammation of the nose, swelling and hypersecretion, could not be controlled by astringent drugs in weak solution applied by brush or spray. Every rhinologist will remember the repeated and discouraging failures which forced him to the conclusion that he must pin his faith on therapeutic measures other than the spray and douche if he would cure his patients who were suffering from chronic nasal disease; and, by the way, that word *cure* was handled very guardedly by the nasal physician in those days. It was the patient who introduced it into the conversation To-day we are not obliged to run away f.om this word.

Another of the fundamental fallacies which wasted the valuable time of the physician who treated diseases of the upper air-passages, between the years 1860 and 1870, was that he considered the larynx clinically the most important part of the respiratory tract. Diseases here were carefully studied and treated, while nasal disorders were ignored. It seemed to be felt that the small length of the air-tube called the larynx was separated pathologically from every other portion of the respiratory tract. It is now known that laryngeal catarrhal inflammation is almost always secondary to and dependent upon the same character of inflammation of the nose, and no matter how frequently and to how great an extent laryngeal catarrh is benefited by topical applications, relapses will always speedily occur until that great source and cause of inflammation of the upper air-passages—*nasal disease*—is controlled. Ten years ago there were many laryngologists, and they worked at the wrong end of the upper respiratory tract. To-day there are numerous rhinologists, because it has been demonstrated beyond peradventure that catarrhal inflammation commences in the nose and extends downward.

The real and remarkable progress in the treatment of nasal disease during the past eight years has been attained because we have at last appreciated: 1st. That the anatomical structure of the nasal tissues is a peculiar one, differing in a marked way from other mucous surfaces and consequently demanding different treatment. 2d. That this peculiar structure performs a remarkable physiological function; and 3d. That the disease which was formerly known as chronic nasal catarrh, and now more frequently called chronic hypertrophic rhinitis is not satisfactorily explained by the pathology which our writers attribute to catarrhal inflammation of ordinary mucous membranes.

Let us review this ground for a moment. First, we have said that the older methods of treating nasal disease—methods which were composed mainly of the application of astringent drugs to an oversecreting mucous membrane, were ineffectual because the physician failed to recognize the peculiar anatomical structure of the nasal tissue and its remarkable physiological function. In examining the nostrils of patients suffering from the most common variety of nasal disease, observers were always impressed with three pathological conditions: 1st. The occlusion of the nasal cavities by swelling of the nasal tissues. 2d. The heightened color of the mucous membrane; and 3d. the presence of hypersecretion. The indications for treatment seemed clear: to control all of these symptoms by the application of astringent remedies. But it was found that so-called astringents seemed to be stimulating or irritating in their effect, for all three of the pathological conditions were increased rather than diminished by such treatment. This failure seems to me to be satisfactorily explained by this one fact, viz: that nasal operators were dealing with an erectile structure and not a simple mucous and submucous tissue, *endeavoring to astringe the physiological erectility of a cavernous body* with weak sprays of silver, copper, tannic acid, and zinc. We can understand now that these daily applications were just the peripheral stimulation needed to produce a constant erection of these bodies, and that when they were persisted in for some time the continued erection of the nasal tissues was at length followed by paralysis of the overtaxed vaso-motor system which regulates the quantity of blood flowing to the nasal turbinates. The result was a more or less permanent occlusion of the nostrils by swellings composed not so much of hypertrophied tissues the result of a chronic rhinitis, but composed of the dilated venous sinuses of a cavernous body whose power of erectility and contraction had been abolished by the application of

irritating drugs. Every application of cocaine to these nasal swellings demonstrates that they are only to a slight degree made up of hypertrophied connective tissue, since they are entirely effaced—completely levelled to the plane of the normal neighboring tissues by the action of this drug.

It will be seen, therefore, that the name "hypertrophic rhinitis" is very frequently misapplied. Not only is it not a hypertrophic process which characterizes this disease, but the significance of the term rhinitis, as indicating an active inflammatory process, is also very frequently misleading, since the swelling of the soft tissues seen in chronic nasal disease is composed of bloodvessels permanently dilated by over-physiological action or by external irritants.

We have said that permanent dilatation of the bloodvessels which form the cavernous turbinated bodies may come about by reason of over-physiological action. This is a point worth considering. As long ago as 1769, Morgagni called attention to the "red thickness of the membrane of the nose," but seems not to have appreciated that this was an erectile structure. And Toynbee,[1] writing in 1868, says: "Many years ago I pointed out the peculiar erectile tissue of the nasal mucous membrane—this tissue is a most efficient respirator." In 1853 Koherausch demonstrated what he called a "cavernous network of veins" by injecting the submucous nasal structure through the jugular vein. Hyrtl and Kölliker made similar experiments and arrived at the same conclusions as to the presence of this true nasal erectile structure. But to Dr. H. J. Bigelow, of Boston, the credit is due of describing, in the year 1875, this erectile structure in detail, and he called attention also to the alternate swelling and contraction of this structure, naming it the "turbinated corpora-cavernosa." Bigelow obtained his results by injecting the nasal structure locally. We have therefore in the respiratory portion of the nose, especially abundant over the inferior turbinated bone, a true membrana mucosa in the meshes of which is formed an erectile tissue.

That so unusual a structure as erectile tissue was placed in the nose for a distinct purpose no one can doubt. We believe that the expansion and contraction of this nasal tissue are not due to inflammatory congestion, but are physiological acts, which are regulated by a finely adjusted nervous mechanism as sensitive as that which presides over the movement of the iris. Since it has been known that inspired air is elevated in temperature to the proper degree for its reception into the lungs by warmth obtained almost entirely from the nasal tissues, and that from this same source alone the inspired air receives the necessary amount of moisture, it is more than probable that the nasal erectile tissue changes in size constantly with every variation of the thermometric and barometric scale.

I would refer here to the experiments done by Aschenbrandt,[1] which I have not time to quote, and also to an article by Greville Macdonald,[2] M.D. Both of these gentlemen have demonstrated, by an arrangement of tubes which allowed the air to pass into one nostril and out the other, that air inhaled at 53.6° Fahr., and also at 46.4°, was exhaled from the opposite side of the nose (without having passed to the lungs) at a uniform temperature of 86°. And it was also demonstrated that air became charged with water to the point of saturation, by its passage through the nostrils. Keeping in mind these important physiological functions performed by the nasal tissue, the necessity for perfect nasal respiration and the evil effects of mouth-breathing will be apparent.

The intense functional activity of the nasal tissues, together with the fact that they are exposed to the irritation of dirt and dust from without and frictional irritation from within, due to contact with projections of bone and cartilage upon the septum; these factors greatly predispose to constant distention of the venous sinuses of the nose and eventual vasomotor paralysis. We have here, then, the so-called hypertrophies of the most common form of nasal disease, not due properly to a catarrhal inflammation, but to a great extent caused by the functional activity of an erectile structure. This much and more has been learned in regard to nasal anatomy and physiology, and this knowledge will, I believe, substantiate the third proposition of this paper, viz., "That the disease which was formerly known as chronic nasal catarrh, and now more frequently called chronic hypertrophic rhinitis, is not satisfactorily explained by the pathology which our writers are in the habit of attributing to catarrhal inflammation of ordinary mucous membranes."

To proceed one step further: if the nostrils are partially or wholly occluded by the bagging of the nasal tissues, the remaining pathological appearances and the subjective and objective symptoms of nasal catarrh are satisfactorily explained by the mechanical causes which are incident to nasal obstruction. For example: as to the matter of hypersecretion—which to the patient is the most annoying of all symptoms and is the most obstinate one with which the physician has to contend—*its* presence is also to be explained on other grounds than the result of catarrhal inflammation. This apparent hypersecretion may manifest itself in two ways: first, there may be simply an outpouring of serum from the over-distended vessels of the erectile struc-

[2] Macdonald: On the Mechanism of the Nose as regards Respiration, etc. British Med. Journal, December, 1888.

ture, as seen in the periodical exacerbations of the disorder called hay-fever, and in many cases of very sensitive and irritable nostrils. And, secondly, it may be said that the collections of mucus and muco-pus which are blown from the nose and hawked down from the post-nasal space, although apparently much greater in quantity than the normal mucous secretions, in many instances do not represent an increased glandular secretion, but rather a stasis of the normal flow. Stasis of the nasal secretion takes place, first, because the air current is too feeble in a partially occluded nostril to waft it on; and, secondly, because the action of the ciliated epithelium is also abolished in an obstructed nostril. If hypersecretion can be explained in this manner, it is another strong argument against the name rhinitis or any word ending in *itis*.

It is not within the province of this paper to speak of the intimate relation which careful study during the past five years has discovered to exist between nasal disease and many reflex phenomena such as bronchial-asthma and the asthma associated with hay-fever. We can only mention in passing, nasal coughs, the hemicrania, migraine and the various neuralgias due to nasal irritation, the direct and reflex aural phenomena cured by relieving nasal irritability, the close relation between nasal congestion and that of the conjunctiva; and it may come to pass that the rhinologist as well as the oculist will claim his share of the work in the treatment of epilepsy and chorea by demonstrating nervous relationship between these diseases and disorders of the nasal chambers.

As we have already said, it has been positively demonstrated that laryngeal and bronchial inflammations are secondary in the majority of instances to nasal disturbances: 1st, by the extension downward of the process; 2d, by the abolition of the nasal function; and 3d, by reflex causes. The surgical apparatus and the therapeutic measures which the rhinologist possesses to-day are adequate to correct the pathological conditions present in nasal disease. Cocaine and careful antiseptic precautions permit him to remove whatever may seriously obstruct nasal respiration and function whether it be soft tissue, cartilage, bone or tumor, without pain or constitutional disturbance to the patient. The perfected atomizers still have their use in properly cleansing the mucous membrane before the essential treatment is commenced. The storage battery which furnishes the electric light for illumination, the galvano-cautery for removing soft swellings and also the motive power to propel the trephine, the saw and the drill, is an invaluable addition to the nasal operator's equipment. While it is necessary to remove enough of soft or hard obstruction to secure free nasal respiration, *it is imperative to leave uninjured sufficient soft nasal structure to perform perfectly nasal function.* Too much emphasis cannot be placed upon this caution.

We have in considering the peculiar anatomy and physiology of the nose, and the more recent pathology of nasal catarrh, apparently been led somewhat away from the line of thought the title of this paper would naturally suggest. But it was not intended to enter into the details of therapeutics, but rather to endeavor to formulate the broad principles upon which the present very efficacious methods of treating nasal disease are based. The indications for treatment are clear. First. To secure free nasal respiration and so obtain normal nasal function. Second. To prevent the collection and inspissation of nasal secretions by insisting upon healthy nasal drainage. Third. To abolish over-sensitive areas in the nasal chambers which have been found to occasion near and remote reflex disorders. Fourth. To do away with the frictional irritation arising from contact of the distended turbinated bodies either with a deviated nasal septum itself or the convexities of bone and cartilage projecting from the nasal septum.

ARTIFICIAL MENSTRUAL SUPPRESSION.

By A. REEVES JACKSON, M.D.,
Professor of Gynecology in the College of Physicians and Surgeons, of Chicago.

At a meeting of the Gynecological Society of Chicago, on November 16, 1888, I read a paper entitled "On Some Uncured Cases of Uterine Hemorrhage," which was subsequently published in The Medical News. In closing the discussion which followed the reading of the paper, I made the following statement:

> "Loewenthal has reported several cases in which he used hydrastis for preventing menstruation in persons to whom it (menstruation) was injurious; chlorotic and anæmic patients, he affirms, have been effectually cured by the use of hydrastis, given so as absolutely to obliterate the function of menstruation."

The subject of the artificial suppression of the menstrual discharge thus alluded to would seem to have excited a good deal of interest, for I have received several letters from physicians in various parts of the country asking for details concerning this method of treatment.

The statement, I may at once say, was erroneous. It was *not* Loewenthal, but M. Kugelman who is said to have "easily obtained suppressions by the use of hydrastis canadensis."[1] Loewenthal's method consists in the use of vaginal injections of hot water (122° F.) and rest in bed for a time. A paper embodying his experience in this mode of treatment appeared in the *Bull. Génér. de Thérap.*, and a

[1] American Medical Digest, 1886, p. 131.

summary of the same was reported in the *American Med. Digest.*[1]

Contrary to the general belief that when the menstrual discharge becomes suppressed without appreciable physiological cause efforts should be made to induce its reappearance as a necessary condition of health, Loewenthal holds the opinion that in many women, who are not in good health, the menses, far from being salutary, are pernicious; and that when nature does not suppress the flow under such circumstances it becomes the duty of the physician to do so. His experience with this method is given in the paper to which I have referred, and comprises 23 patients, of whom 18 were chloro-anæmic, 2 were hysterical, and 3 convalescent from severe maladies.

"The chloro-anæmic patients were cured in this way without further treatment. The amelioration was rapid, and generally followed the first artificial suppression. In one case, a cure was effected only after eight suppressions. Of the two hysterical patients, the condition of one only was ameliorated. No report is given concerning the convalescents. Loewenthal observed no evil results in any case following complete artificial suppression of the flux."

For the past six years I have endeavored to lessen, as completely as possible, the amount of uterine hemorrhage, whether menstrual or intermenstrual, in all cases in which the saving of blood seemed to be an important indication, and the means upon which I have especially relied latterly for this purpose has been the use of the vaginal tampon, substantially in the manner recently recommended by Dr. E. C. Gehrung, of St. Louis.[2]

I prepare twenty to thirty masses of absorbent cotton by dipping them in a mixture of vinegar and water, one part to four, and squeezing them until they are merely damp. They should have the size of a small walnut, but should be pressed into the form of a flattened disk. I then place the patient in a knee-chest posture, with the hips elevated as much as possible, and introduce a bivalve speculum. This permits the entrance of atmospheric air, and the vagina is widely expanded. With a pair of uterine dressing forceps the cotton disks are then placed; first, around the vaginal portion of the cervix, then over and against the os uteri, and, finally, the others are placed evenly in place until the upper two-thirds of the vagina are occupied. The disks should be placed with only a moderate degree of firmness, otherwise pain may follow the procedure. If the lower third of the vagina be left vacant the patient will experience no difficulty in urination, and may thus avoid the necessity for catheterization. At the end of twenty-four hours I examine the lower tampons through the speculum, and if they be bloody I remove the entire packing and replace it. If they are free from stain, I permit them to remain another period of twenty-four hours before removal. Sometimes a single tamponade suffices, while in other cases I have had to repeat it five or six times.

I have found this method of treatment especially valuable in cases of bleeding myomata. In many of these, after the failure of curetting, ergot, and hydrastis to check excessive hemorrhage, I have succeeded by the systematic employment of the tampon, inserted as soon as possible after the commencement of hemorrhage, in reducing the amount lost to not more than one-tenth of what the patient had previously sustained.

I have observed fairly good results from the use of ergot in a number of instances, and excellent results in a few. But in nearly all of these the uterus was in a soft, bulky condition, such as is found in the early stages of subinvolution and in some cases of fibro-myomata.

In consequence of the recommendation of Prof. Schatz, of Rostock, Germany, who first brought into prominent notice the action of hydrastis canadensis as a uterine tonic, and the subsequent corroborative experience of Dr. R. W. Wilcox, as reported in the *New York Medical Journal*, I have used that drug in several cases of excessive menstruation. Although its action is said to resemble that of ergot, I found it most useful in those cases in which ergot had utterly failed. My experience with it has not been so satisfactory as that of the writers whom I have mentioned. The dose should be twenty drops of the fluid extract, or one-quarter to one-half a grain of hydrastin three or four times a day.

Loewenthal's reported success with the use of hot water injections greatly surprises me. While it is well known that the application of water at a temperature of 120° or over, when continued for twenty or thirty minutes, will cause a temporary blanching of a mucous membrane, this effect does not last very long, and if the part be examined an hour later it will be found turgid and red from the reactionary congestion. If the application of the heat could be continuously maintained for hours rather than minutes the effect would, doubtless, be more satisfactory. As a repressor of uterine hemorrhage hot injections have failed in my hands.

While I would advise the use of ergot and hydrastis as adjuvants to the tampon, when the object is to diminish the amount of uterine blood loss, I have come to the point of feeling confidence only in the latter remedy. Yet, I have to say that in not a single instance have I succeeded, with any or all of the means mentioned, in effecting a permanent suppression of the menstrual function during the period of active sexual life.

[2] "Repression of Menstruation as a Curative Agent in Gynecology." Amer. Journ. Obs., November, 1888, p. 1138.

MEDICAL PROGRESS.

Chloroform as an Internal Remedy.—Dr. Stepp, of Nürnberg, noting the observations of Salkowski on the disinfecting power of chloroform water, determined to make trial of chloroform internally in a considerable number of diseases. It may here be remarked that the use of chloroform in aqueous or spirituous solution is less common in Germany than in this country, where the familiar so-called "æther chlor." forms a portion of a very large number of prescriptions. In gastric ulcer Dr. Stepp gave chloroform (fifteen grains in a five-ounce bismuth mixture) with great effect, and believes this to be due to its disinfecting, astringent, and stimulating properties. In various affections of the mouth and throat—as follicular pharyngitis, catarrh of the pharynx, gingivitis, and diphtheria—washes and gargles containing chloroform proved very beneficial. In one case of severe psoriasis of the mucous membrane of the mouth, which had been unsuccessfully treated by several medical men, chloroform water effected a complete cure. Two cases of pneumonia treated with chloroform did so well that Dr. Stepp means to make a further trial of it in this disease. Perhaps the most encouraging results were obtained in cases of typhoid, though only six of these were thus treated. The value of chloroform in some cases of fever was, we believe, shown some twenty-five years ago in the Dublin hospitals, but it has never come into general use even in this country as an antipyretic.—*Lancet*, March 9, 1889.

Use of Menthol Internally.—The *Wiener klin. Wochenschrift* of March 7, 1889, states that menthol, which, on account of its great anodyne action, has been largely used as a local application, has of late been administered internally as an antineuralgic in hemicrania, infraorbital neuralgia, and headache, as well as for the relief of the pain of rheumatism and sciatica, in doses of from four to fifteen grains.

Dr. Mac. Laury (*Therap. Gazette*) gives the following prescriptions for the administration of this preparation:

℞.—Alcohol . . . . . ℥j.
Menthol . . . . . ℥ij.
Glycerin . } . . āā ℥j.—M.
Simple syrup }

One teaspoonful in warm water when required.

℞.—Menthol . . . . . ℥j.
Sugar of milk . . . . grs. ix.—M.

Administer in 12 capsules; one or two capsules to be taken daily.

Menthol can also be combined with antifebrin and antipyrin, as in the following:

℞.—Menthol } . . . āā ℥j.
Antifebrin }
Sugar of milk . . . . q. s.—M.

To be divided into 24 powders, administered in capsules; two capsules to be taken daily.

New Antidote for Morphine.—Prof. Bokai, of Klausenberg, believes that the best antidote for morphine is picrotoxin. The two substances act in an opposite manner on the respiratory centre, morphine paralyzing its action, while small doses of picrotoxin increase it. As in poisoning by morphine death occurs from paralysis of the respiratory centre, and as picrotoxin hinders this paralysis, it follows that picrotoxin is likely to be of real use in morphine poisoning. In morphine poisoning, diminution of the blood-pressure plays an important part, but picrotoxin enjoys the property of stimulating the vaso-constrictor centre of the medulla and thus counteracts the effect of the morphine. Once again, the action of these two substances on the cerebral hemispheres is also of an opposite character. As atropine, the only known antidote of morphine, cannot be administered in large doses, it is certainly desirable that other means of combating morphine poisoning should be sought for. Prof. Bokai thinks that picrotoxin may be useful as a substitute for preparations of nux vomica, and he also believes that it will be found of value in preventing chloroform asphyxia.—*Lancet*, March 9, 1889.

Antiseptic Vapors in the Treatment of Diphtheria.—Dr. Daniel Paterme (*Bull. gén. de Thérap.*, vol. 38) bases this mode of treatment on the assumption that diphtheria is at the beginning a general affection and that the local symptoms always follow the primary general infection. Diphtheria demands therefore not a local, but a general antiseptic treatment.

The mode of treatment advocated by Dr. Renon would thus be in place here, which is: 1st. Saturating the inspired air with steam which has been thoroughly impregnated with antiseptic substances. 2d. A nourishing diet and the administration of tonics such as quinine. 3d. Not touching the throat at all.

Renon uses as an antiseptic a solution of carbolic and salicylic acids in alcohol; of this one tablespoonful is added every three hours to four pints of boiling water.

The cases treated by the author were: Thirty cases of diphtheria of the respiratory passages, 29 with croup, with 24 recoveries and 6 deaths; 23 tracheotomies with 18 recoveries (amongst the latter were 3 infants aged eleven, twenty-one, and twenty-four months respectively).—*Centralbl. f. d. ges. Therapie*, March, 1889.

A New Aliment.—Dr. Dujardin-Beaumetz recently exhibited at the Academy of Medicine a new alimentary substance, "fromentine," which is obtained from wheat by the aid of special mill-stones. Fromentine is the embryo of the wheat reduced to flour. It contains three times more nitrogenous substance than meat, and a strong proportion of sugar. Hence it would appear that it might advantageously replace powdered meat as a concentrated food. It may be employed for making soups, and even for making biscuits, the taste of which would not be disagreeable.—*Lancet*, March 9, 1889.

Eseridin.—Eseridin is a new alkaloid of calabar bean discovered by Dr. Bihringer; it is closely related to physostigmine. In medicinal doses it produces diarrhœa. Its toxic doses are six times as large as those of physostigmine; the production of intestinal mucus seems to be increased by its administration. It can be used as a laxative like physostigmine, or as a motor excitant; it has not the cumulative action of strychnia. Contraindications to its administration are diseases in which the brain and spinal cord are over-stimulated.—*Deutsche med. Wochenschrift*, Feb. 28, 1889.

Resection of the Ensiform Cartilage.—An important paper has recently been presented to the Royal Academy of Medicine and Surgery of Naples by a young surgeon, Dr. Rinonapoli, of Collamele, in the province of Aquila, giving the details of an operation for resection of the ensiform cartilage. Only one such case has been previously recorded—by Linoli, in 1857. A man was injured by a horse rearing and falling back upon him. His chest was violently compressed, and the ensiform cartilage dislocated backward. The displaced cartilage, by its pressure on the stomach, was productive of very severe gastric disturbance, which at length became so great that not even the smallest quantity of milk could be taken without terrible pain. The patient rapidly wasted away, and his life was despaired of. Various diagnoses were made, but it was left for Dr. Rinonapoli to discover the true state of affairs. Being convinced of the accuracy of his diagnosis, and, fortified by the opinions of two colleagues, Dr. Rinonapoli gained the consent of the patient and his friends to an operation. The minutest antiseptic precautions (carbolic acid and perchloride of mercury) were observed. An incision six centimetres long was made, the upper third being over the sternum. Dissection was carefully carried down to the peritoneum, which was not opened. The cartilage was separated from the structures enveloping it, and, finally, its attachment to the sternum was divided by passing a probe-pointed bistoury behind and cutting forward. The wound was carefully cleansed and brought together by sutures. In the course of five weeks the patient had completely recovered. The points of interest connected with the case are: 1. That it is only the second recorded. 2. The peritoneum was not opened. 3. It was undertaken by a young surgeon in a country district in Italy, who, with the assistance of two other country surgeons, carried it through in the most praiseworthy manner. Dr. Rinonapoli worthily won his admission to the Royal Academy of Medicine of Naples, for which Professor Fusci stood his sponsor.—*Lancet*, March 16, 1889.

Rectified Oil of Turpentine in the Treatment of Idiopathic Croup.—DR. M. LEWENTANER, in the *Centrabl. f. klin. Med.*, No. 8, 1889, reports the two following interesting cases of croup treated with this drug: A two year old boy suffered from a cold the symptoms of which (hoarseness and stenosis), became so alarming that the little patient was brought to the hospital to undergo the operation of tracheotomy. On the seventh day of the illness Dr. Lewentaner found the child suffering from asphyxia, with pale face and pulse hardly perceptible. He immediately administered a coffeespoonful of rectified oil of turpentine and ordered ice compresses to be applied to the throat. The following day improvment was marked, one coffeespoonful of oil of turpentine being found sufficient to cause expectoration of the membranes. The following mixture was then administered:

℞.—Rectified oil of turpentine	4	parts.
Sweet oil of almonds	10	"
Simple syrup	20	"
Mucilage of gum arabic	40	"
Yolk of egg	15	"
Cinnamon water	50	" —M.

Dose, a coffeespoonful every two hours.

The child recovered entirely.

The second case was a four year old boy, who had been treated unsuccessfully for eight days. Dr. Lewentaner found him to be suffering from severe croup with stenosis of the larynx. He immediately administered one coffeespoonful of oil of turpentine and then ordered the following to be inhaled day and night:

℞.—Oil of turpentine, Tincture of eucalyptus globulus, Carbolic acid,	āā	4 parts.
Alcohol	300	"
Distilled water	696	" —M.

Immediately after the turpentine had been taken the child coughed freely and expectorated some slimy-purulent sputum and gray-white membranes, which latter had the exact cast of the trachea. The membranes forming again, the author administered the following morning and evening, and also on the morning of the third day, one coffeespoonful of the oil of turpentine. Complete recovery followed. Dr. Lewentaner attributes the recovery of these two cases to the specific action of turpentine.—*Wiener med. Presse*, March 10, 1889.

A Tracheotomy Tube in the Bifurcation of the Bronchi.—A somewhat remarkable case is reported by Professor Pieniczek in the *Przeglad Lekarski*, where a caoutchouc tracheotomy tube, which had been inserted ten years previously, suddenly slipped and fell down the trachea so as to be completely lost to sight. At first the patient, who was an elderly man, coughed violently, but after a little while the irritation entirely ceased, and though he could feel the presence of the foreign body at the third and fourth costal cartilages on the right side, it did not occasion him any serious inconvenience. It had remained *in situ* about seven weeks when it was removed. In order to accomplish this the patient was chloroformed, and as sufficient anæsthesia for the purpose was not procured by this means, the mucous membrane was painted with a twenty-five per cent. solution of cocaine. By means of a laryngoscopic mirror introduced into the laryngeal opening, the foreign body could be distinctly seen and its position made out. It was lying at the bifurcation, its convexity upward, and its larger end directed toward the right bronchus. With the help of the mirror, a blunt hook was passed down to the tube in such a manner that it was caught up and so extracted. Professor Pieniczek remarks that it would have been almost impossible to secure the tube without the aid of the mirror, as its position could not otherwise have been determined, and without an exact knowledge of this any manipulation with instruments would have been dangerous and probably useless.—*Lancet*, March 16, 1889.

The Value of Iodol.—DR. TALENTI, from his experiments with powdered iodol, arrives at the following conclusions:

1. Iodol applied directly to the eye is not an irritant.

2. Its use is indicated in solution of continuity of the cornea. Introduced into the anterior chamber it exerts no injurious action on the iris.

3. Its application is of great service in catarrhal conjunctivitis and in hypopyon of keratitis.

4. Iodol in the form of powder is more efficacious than the ointment.

5. The different results obtained by different authors are due to the various manners of application.

6. Being non-irritant, inodorous, and not more expensive than iodoform and possessing all the antiseptic qualities of the latter, it should replace it.—*Revue gén. d'Ophtalmologie*, January, 1889.

Muscular Atrophy in Pregnancy.—M. Denos has recently described an interesting case of muscular atrophy developing with great rapidity in all four extremities during pregnancy already complicated with uncontrollable vomiting. The patient was thirty-one years old, already exhausted by two previous pregnancies, by severe metrostaxis, and by an obstinate skin affection. During the third pregnancy uncontrollable vomiting set in. Toward the end of the fourth month the muscles of the lower extremities began to atrophy. Three or four days later the arms were involved. Pain and formication were complained of by the patient. Cutaneous, muscular, and electrical sensibility were preserved. The functions of the bladder and rectum remained intact. The temperature was subnormal, and the intellectual faculties, especially the memory, were weakened. Premature labor was induced after due deliberation. The patient recovered from confinement, and at once her general condition improved. In the course of two months' holiday in the country, with liberal diet, the atrophied muscles began to regain their normal condition. As galvanism caused sharp pains, she refused to allow its application to the affected parts. On her return to Paris, however, it was employed in conjunction with wet packing. In the following spring the patient was able to walk, leaning on two sticks. She was once more sent to the country for two months. On her return she appeared to be cured. From a skeleton-like condition she had become actually corpulent. This remarkable case was read before the Paris Académie de Médecine on January 15th.—*British Medical Journal*, March 16, 1889.

A New Method of Treatment for Epidemic Diphtheria.—Dr. A. Hennig, of Königsberg, recommends, in the *Berl. med. Wochen.*, Nos. 7 and 8, a new method of treating epidemic diphtheria, the advantages of which lie in its extreme cheapness and easy mode of application. Out of 1054 cases treated the mortality was, both in epidemic and scarlatinal diphtheria, but 2.7 per cent., and in epidemic diphtheria alone only 0.9 per cent. The mode of treatment consists in the use of lime-water and applications of ice. When the disease affects the mouth and throat, and not the nasal cavity or nasal membranes, the author directs the patient to gargle every fifteen or thirty minutes, according to the severity of the disease, with lime-water, and after every act of gargling to swallow from three to five drachms of the liquid, according to the patient's age. Those who are unable to gargle, take the drug internally in doses of from five drachms to one ounce; while for those who are neither able to gargle nor to swallow a spray should be used. This spray, however, should only be applied during inspiration, as the carbonic acid of the expired air, acting upon the lime-water, forms a carbonate of lime, thus rendering the action of lime-water entirely useless. The quantity of lime-water swallowed amounted often to six pints during twenty-four hours, which could be taken without apparently injuring the organism. The lime-water should be frequently freshly prepared, for when allowed to remain exposed to the air for any length of time a white skin forms from the carbonic acid in the air, which later interferes quite perceptibly with the action of the lime-water. With the ice-bag to the neck and lime-water internally the temperature falls considerably, the pulse becomes stronger, swallowing much easier, and the process of exudation abates gradually.

In nasal diphtheria the author simply irrigates the nasal passages with lime-water, which generally suffices to remove the local process. Should the affection involve the larynx, spraying the parts with, and the internal administration of, the lime-water will overcome the affection. Diphtheritic affections of the conjunctiva, or vagina, are treated by the frequent application of wadding saturated with lime-water.

It is the author's opinion that lime-water prevents the further development of the specific causative agent, influences the coagulation of the living albumen, thus preventing any further action of the microbes, and through its power of solving mucin detaches the membranes, which are expectorated. Dr. Hennig thus claims that lime-water is a specific for diphtheria, and that this mode of treatment destroys the fatality of this disease occurring after the sixth year of age, as among 1054 cases not a single death occurred in patients over six years of age, although fully 60 per cent. of the cases treated had passed that age.—*Wiener med. Presse*, March 10, 1889.

Popliteal Aneurism Treated by Digital Compression.—Dr. G. L. Richards reports (*Trans. Rhode Island Medical Society*, 1888) a case of aneurism of both popliteals in a man aged fifty-three years, cured by digital compression lasting in one forty-four and a half hours, and nine months later, in the other, fifty hours.

Antipyrin in Sciatica.—Dr. Gabriel Covarrubias, of Limache, reports (*Revista Medica de Chile*, December, 1888) a case in which he cured sciatica with antipyrin. The patient had been confined to his bed for two months, and was unable to move his left leg. The hip-joint was so painful that the gentlest examination with the fingers could scarcely be borne. The slightest pressure over the gluteal, sciatic, and trochanteric regions made the patient cry out with pain. Sleep had been impossible for some nights, and there was considerable wasting. The severity of the symptoms, coupled with the fact that there was slight rise of temperature every evening, led Dr. Covarrúbias to suspect the existence of an iliac abscess; an exploratory puncture was therefore made, with a negative result. Sciatica having then been diagnosticated, injections of morphine in the infected part, anodyne applications, general antirheumatic treatment, salicylate of soda, iodide of potassium, sulphate of quinine, tincture of gelseminum, bromide of potassium, etc., all were tried without the least effect. Tonic treatment with iodide of iron, cod-liver oil, etc., proved equally futile. Antipyrin was then given in doses of eight grains, with an equal quantity of quinine, three times a day. The day after this treatment was begun the patient wished to get up; the pain had ceased, and he could move the affected limb quite freely. Ten days afterward he left the hospital completely cured, and having gained considerably in weight.—*British Medical Journal*, March 16, 1889.

Codeine and its Uses.—DR. FISCHER reports (*Correspondenzbl. f. Schweizer Aerzte*, 1888, 19; *Bresl. artzl. Zeitschr.*, 1889, 2) that for the past five years he has used codeine in all cases in which morphine was indicated, and has found it of service in the treatment of phthisis, in bronchitis, and in all cases of sleeplessness not due to severe pain. Externally as well as in the form of suppositories or fluid inhalations or ointments the results were satisfactory, no unfavorable symptoms whatsoever being observed. A dose of ⅓ to ½ grain of codeine is equal to ⅙ grain of morphia. The best forms for administration are pills, powders, or syrups. In ordering pills each pill should contain from ⅓ to ¾ grain of codeine. This mode of administration will be found the best when treating abdominal pain or diabetes:

℞.—Codeine . . . . . 15 grs.
Extract of gentian } . . . q. s.—M.
Powdered licorice }
Make thirty pills.

For irritable coughs the syrup is preferable, the French formula of which is:

℞.—Codeine . . . . . 4 grs.
Alcohol . . . . . ℥iss.
Syrup . . . . . ℥iij.—M.

Dose, one tablespoonful.—*Med.-Chirurg. Rundschau*, February 15, 1889.

Hepatic Abscess Bursting into the Pericardium.—DR. JOAQUIN L. JACOBSEN, of Havana, reports (*Revista de Ciencias Medicas*, February 20, 1889) a case in which an abscess of the liver, which was not recognized during life, was found after death to have burst into the pericardium. The complication is so rare that Dr. Jacobsen has been able to find only ten cases previously recorded. The patient was a white man, aged thirty-nine, who had been a heavy drinker, and had suffered from malaria. He had been troubled for about a year with dyspeptic symptoms. He was pale and slightly jaundiced, and had lost flesh. Both the liver and the spleen were enlarged, and there was some tympanites. He complained of constant pain, sometimes referred to the epigastrium, sometimes to other parts of the abdomen. Percussion in the epigastric region caused a little pain, but gave a normally resonant note. He was treated with purgatives and alkalies, and a blister to the epigastrium. The enlargement in the region of the liver increased, but no fluctuation could be detected, and there were no signs of adhesion. Symptoms of intestinal obstruction came on soon afterward, with marked tympanites and dyspnœa, and three days after the commencement of this new phase of his illness the patient died. At the necropsy the lungs were found contracted and pushed toward the posterior and upper part of the thorax; the parietal layer of the diaphragmatic pleura was thickened and congested; the pericardium, which was also thickened, contained a large amount of seropurulent fluid, dark yellow in color; the outer surface of the heart, which was rough and granular, was of the same color. At the lower part of the pericardium, slightly to the left of the middle line, there was an opening with ragged edges, about one and one-third inches in diameter, passing through the diaphragm and communicating with an irregular opening in the posterior part of the convex surface of the left lobe of the liver. For some distance around this opening there were firm adhesions to the diaphragm. The liver was enlarged and somewhat hardened; its right lobe was congested, and in the left there was a large cavity measuring five inches in the transverse by four inches in the vertical and antero-posterior diameters, and full of yellow pus. The spleen, which was enlarged and softened, presented two large, milky-looking patches on its outer surface. The gastro-intestinal mucous membrane was thickened and injected. All the other organs were healthy.

Dr. Jacobsen points out that the abscess was in the posterior part of the liver, leaving a considerable portion of the front part of the left lobe untouched, while the symptoms did not clearly indicate any affection of the liver beyond what was consistent with the patient's gastro-intestinal disorder and alcoholic antecedents. Exploratory puncture could hardly have been successful even if it had been thought justifiable.—*British Medical Journal*, March 16, 1889.

Treatment of Phlegmasia Dolens.—

℞.—Extract of opium }
" of belladonna }
" of hyoscyamus } āā 3 parts.
" of hemlock }
Vaseline . . . . . 30 " —M.

This ointment to be applied along the course of the inflamed vein.—*L'Union Médicale*, March 9, 1889.

Simultaneous Extirpation of the Spleen and a Kidney.—At a recent meeting of the New York Surgical Society, DR. R. F. WEIR presented a lacerated spleen and a kidney with its emulgent veins torn across, which he had removed by laparotomy from a girl aged eleven, who, twenty hours previously, had fallen a distance of twenty feet and sustained abdominal injuries, most marked in the left side, and demanding surgical interference, as the patient's condition had been fairly good. The peritoneal cavity had been found filled with blood, over a pint being eventually removed. The kidney, dislocated downward to the level of the iliac crest and surrounded by a large amount of blood which had escaped into the retroperitoneal tissue, projected so much toward the middle line as to require an immediate investigation, which was made by cutting through its peritoneal covering. It then appeared that it was held only by its artery, its emulgent veins being torn across. The artery had accordingly been tied and the kidney removed, and lumbar drainage had subsequently been made. After the renal extirpation, bleeding still going on, a rapid examination had shown that the source of the bleeding was in the spleen, which was deeply lacerated on its median aspect above the hilum. This also had been easily brought into view, its vessels clamped, and the organ removed. The stump held in the clamp had then been readily tied; the abdominal cavity had then been sponged out and the wound closed. For a few hours it had seemed as if there was a decided hope of the patient's recovering, even from such a severe surgical procedure. However, death had ensued nine hours after the operation.—*New York Medical Journal*, March 30, 1889.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE . . . . . $5.00.

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, APRIL 6, 1889.

THE MEDICAL EXAMINERS' BILL IN PENNSYLVANIA.

MEDICAL thought in these times moves rapidly. It was but the other day that only the most advanced leaders in medical education asserted the necessity for a three years' graded medical course. Now, we find among our leading teachers from the various colleges in this city a number insisting on four years, and even asking that it be made legally compulsory. Again, when the idea of a State Board of Examiners was first broached, a few years since, it was scouted at and utterly rejected, especially by the teachers, who naturally opposed having their work revised by any such Board. Now we find its leading friends are from this same class.

The recent bill introduced into the Pennsylvania Legislature at the instance of the State Medical Society was a perfectly fair bill. It left the selection of the personnel of the Board to the Governor, and the profession were well content to trust any fair-minded Governor, with the advice and consent of the Senate, not to pack the Board in the interest of any one school, no matter what his personal predilection might be. The amendment added to it at the instance of the homœopathists and eclectics has a specious appearance of fairness, in that it absolutely prevents the Governor from appointing a majority of the Board from any one school; but its real unfairness is seen when we consider the fact that practically there are but two schools, the regulars and the irregulars, and that if any question should arise touching the relations of the different schools, the homœopaths and eclectics would, of course, unite in opposition to the representatives of regular medicine. The latter being relegated to a perpetual minority, by this amendment, the irregulars could always carry out any plan of examination that they might agree upon. It is especially to be remembered that this legal "minority" represents 6000 regular physicians, and that the "majority" represents about 700 homœopathics and 300 eclectics.

Any one familiar with the status of medical education must know that even in the ranks of the regular profession (the teachers being barred out) it will not be very easy to obtain first-class examiners, thoroughly educated, abreast of the times, both able and willing to assume the duties incumbent on such a Board. Any one familiar with the status of education among the homœopaths and eclectics knows perfectly well that not only is a choice more difficult from their ranks, because it must be made from about 1000 instead of 6000 physicians, but also from a body of men, as a rule, vastly inferior in their scientific attainments; and yet it is from this less scientific minority that the majority of the Board *must* be selected, according to the amendment. How likely would such a majority be to enforce thoroughly the examination that ought to obtain, especially when thoroughness would presumably tell most against their own friends?

The friends of the bill, however, are so earnest in their desire for a better medical education that they are willing to accept it, deeming it at least as the first step, and also believing that our colleges will be careful to graduate only such men as will be able to pass such examinations as a fair-minded Board, however composed, would formulate. But in order that the inevitable tendency of the amendment toward a poorer education shall be counteracted, they have urged a further amendment that every candidate must be a graduate of a medical college having at least a four years' graded course. Some of our best teachers insist upon the need of such a period of study, and claim that the present three years' course is overcrowded with work, and that much work that is essential has to be omitted for want of time.

Whatever may be the outcome of the bill, it is a most hopeful sign of the times that the teachers of the State are not afraid to ask inspection of their work by a Board of Examiners, and are the most ardent advocates of a longer course of study.

RELATIONS OF PATHOGENIC BACTERIA IN DRINKING-WATER.

THE *Deutsche med. Wochenschrift*, No. 2, 1889, contains the results of an investigation conducted by KRAUS in order to determine the relations of different pathogenic and saprophytic bacteria in unsterilized water, which possess considerable interest. First of all, he found no other colony form which bore more than the slightest resemblance to the pathogenic organisms under investigation, namely, Koch's vibrio, the anthrax bacillus, and the bacillus of typhoid fever. He also found that these pathogenic organisms when added to ordinary well or river water soon became incapable of development and disappeared in the course of a few days. No trace could be discovered of Koch's vibrio twenty-four hours after it had been added to the water. The typhoid bacillus could not be detected in the water after six days, and the anthrax bacillus after three days. As both the typhoid bacillus and Koch's vibrio were still capable of development in sterilized water after, respectively, thirty-two and eighty-two days, the inference was that the rapid disappearance of these bacteria was due to the direct action of the common water bacteria. The destruction of the pathogenic bacteria occurred as rapidly in fresh spring water as in the most polluted well-water.

Prof. Koch has demonstrated the fact that the comma-bacillus succumbs to the ordinary putrefactive bacteria, and the results obtained by Kraus show that the water bacteria are allied to the microbes of putrefaction in the nature of their work.

Under ordinary conditions, a limitation tending to the suppression of pathogenic bacteria in water takes place by the domination of harmless forms of microörganisms which deny the means of growth to the less favored pathogenic species. Through this natural proscription the infection of water is probably restricted and in time eliminated.

As most natural waters contain bacteria, it may be assumed that there is always present in water an active, vital agency tending to antagonize and overwhelm, in the struggle for existence, the living morbific organisms, as well as to bring about the transformation of dead organic matter, and that this agency is persistently active until the work of purification is accomplished. If the correctness of this view is established, it gives us further insight into the mode by which water tends to self-purification.

AN Army Medical Board will be in session in New York City, from May 1st to 31st, for the examination of candidates for appointment in the Medical Corps of the Army, to fill existing vacancies, of which we understand there are eight. Persons desiring to present themselves for examination will make application for the necessary invitation to the Secretary of War, before May 1, 1889, stating the place of birth, place and State of permanent residence, and enclosing certificates based on personal knowledge from at least two persons of repute, as to American citizenship, character, and moral habits. Testimonials as to professional standing, from professors of the medical college from which the applicant graduated, and of service in hospital from the authorities thereof, are also desirable. The candidate must be between twenty-one and twenty-eight years of age, and a graduate from a *regular medical college*, evidence of which, his diploma, must be submitted to the Board. Further information regarding the examinations and their nature may be obtained by addressing the Surgeon-General, U. S. Army, Washington, D. C.

THERE has been great activity of late in the Philadelphia Polyclinic. New chairs, of Diseases of the Mind and Nervous System, and of Obstetrics and Diseases of Children, have been established, Drs. S. Weir Mitchell and Edward P. Davis having been elected to the respective professorships. Dr. Mitchell's service at the Infirmary for Nervous Diseases, and Dr. Davis's Maternity Wards at the Philadelphia Hospital, are thus added to the other clinical and hospital facilities. Dr. B. Alexander Randall has been elected Professor of Diseases of the Ear, in place of Dr. Burnett, resigned. Professor Randall has the Ophthalmic and Aural Clinics of the Children's and Episcopal Hospitals.

The hospital accommodations of the present building being insufficient, a large lot, on Lombard Street above Eighteenth, about four blocks from the present location, has been purchased, and work on a new building is being pushed. The Appropriation Committee of the State Legislature has recommended a grant of $20,000 from the Charities Fund, to aid in the erection of the new hospital, provided the institution raises an equal amount. Subscriptions to this end are being solicited, and about one-half the necessary sum has thus far been secured.

Several new departments of instruction have been added under charge of Professors of existing Chairs; notably the Department of Massage (Professors Mills and Wilson), the Special Ophthalmological Course

(Professors Harlan and Jackson), and the Diet Kitchen (Professor S. Solis-Cohen).

At their recent commencements, the degree of Doctor of Medicine was conferred by the respective institutions as follows: Jefferson Medical College, Philadelphia, 212; Missouri Medical College, St. Louis, 82; St. Louis College of Physicians and Surgeons, 54; College of Physicians and Surgeons, Baltimore, 67; Western Reserve University, Cleveland, 43; Western Pennsylvania Medical College, Pittsburg, 36; Ensworth Medical College, St. Joseph, Mo., 9,

Scarlet fever, diphtheria, and measles are extremely prevalent in New York City, as shown by the statistics of the Board of Health for the month of March. The cases of scarlet fever were 1709, while for the corresponding month of last year they numbered but 613. Cases of measles more than trebled, increasing from 236 in March, 1888, to 800 in the month just passed. Diphtheria shows a much smaller percentage of increase, the number of cases for March, 1889, being 811, while in the corresponding month last year the number was 534.

An act empowering the Governor of Florida to appoint three citizens as a State Board of Health has been passed by the Legislature. This Board is to appoint a physician as secretary and State Health Officer, with a salary of $3000 per annum.

The Lacaze prize of 10,000 francs has been awarded to Dr. Malassez, Director of the Laboratory of Histology of the College of France, for his work on tuberculosis.

The Queen has seen fit to recognize the services of that noble sanitarian Chadwick, now that he has passed his ninetieth year, by the bestowal of knighthood. Sir Edwin Chadwick, K.C.B., has been in the forefront of nearly every reform in England for sixty years, and it will be difficult to name a man in this generation whose career has been more beneficent or knightlier than his. His large brain and dignified character have been unreservedly devoted to the cause of the lowly and oppressed.

By the death of Dr. Palmer Howard Canada loses her most distinguished physician, and the profession on this continent one of its best known and most respected members. He had early achieved marked success in practice, and of late years had been the chief consultant in medical cases in the Dominion. An intelligent student, he had, during his long career, contributed extensively to periodical literature, more particularly in Canadian journals, but in the volumes of the *American Journal of the Medical Sciences* are to be found several important papers from his pen, the last but a few months ago. His writings are characterized by unusually clear judgment, careful and thorough observation of facts, and a wide knowledge of current medical literature.

As a promoter of medical education he had labored incessantly, and in the establishment of the provincial medical Boards which form so striking a feature in our neighbors' professional system, he took for years a most active part. As a clinical teacher he did much to establish that thorough system of bedside instruction which prevails at the Montreal General Hospital. During his term as Dean of the Medical Faculty of McGill University, this school has taken a prominent part in the development of advanced modes of medical teaching, and mainly through his efforts an endowment was secured a few years ago and extensive laboratories equipped. Earnest and enthusiastic, with a zeal which seemed to increase with years, the profession has rarely had a more devoted member. In him, too, were combined higher qualities of mind and heart which served to complete an exceptionally attractive character. To his colleagues in Montreal, and to the profession in Canada, we extend our warmest sympathies in their sad bereavement. We hope next week to lay before our readers a brief sketch of Dr. Howard's life.

Dr. Edward T. Bruen, Assistant Professor of Physical Diagnosis in the University of Pennsylvania, died of pneumonia last Sunday, after a brief illness. He was born in 1851, and graduated in medicine at the University of Pennsylvania in 1873. He was visiting physician to the Philadelphia and German Hospitals, and the author of a favorably known work on the "Physical Diagnosis of the Heart and Lungs," as well as of numerous contributions to our periodical literature. He was an earnest student, a close clinical observer, and a skilful practitioner, and his death is a loss to his profession and to the community in which he lived.

Dr. John Swinburne died at his residence in Albany on March 28th, from cancer of the stomach.

He was born in Denmark, Lewis County, N. Y., in 1821, and graduated in medicine from the Albany Medical College in 1846. He was soon made Demonstrator of Anatomy in the College, holding that position four years. In 1861 he volunteered, without pay, as an army surgeon, serving with distinction. In 1864 Governor Seymour made him Health Officer of the Port of New York, and during his six years in that office he established the quarantine service now existing. While abroad with his family in 1870, he took charge of the American ambulance in Paris during the Franco-Prussian War. For this service he was decorated by the French Government with the cross of the Legion of Honor. He returned to this country in 1873. Dr. Swinburne was also prominent in politics, and served as Mayor of Albany and a member of Congress.

SOCIETY PROCEEDINGS.

PHILADELPHIA NEUROLOGICAL SOCIETY.

Stated Meeting, February 25, 1889.

THE PRESIDENT, S. WEIR MITCHELL, M.D., IN THE CHAIR.

DR. S. SOLIS-COHEN read the notes of a case of

OBSTINATE SCIATICA CURED BY DEEP INJECTIONS OF OSMIC ACID.

The method of treating sciatica by deep injections of a solution of osmic acid, is so well known that the present case is reported only on account of its peculiar therapeutic history previous to the resort to the agent in question. Nearly every other medicinal and surgical means known had been tried faithfully but without good result. The details of the case are given merely to show that osmic acid was really the curative agent.

George D., brakeman, æt. forty-five, was admitted to the Department of Clinical Medicine of the Philadelphia Polyclinic, March 24, 1888. For twenty years the patient had had more or less pain in the lumbar region, of gradual development, attributed by him to the fall of a log upon his back while engaged in transport duty during the war. About thirteen months ago he began to feel pain in the right hip extending along the course of the sciatic nerve to the heel. The pain was constant with paroxysms of aggravation, very frequently preventing him from working or even standing erect. Sleep was continually disturbed. He had been under treatment first in the Department for Nervous Diseases, where the diagnosis of sciatica was made, and then in the Surgical Department, for about a year; having been subjected to the influence of a number of medicaments, including, among many others, arsenic, potassium iodide, antipyrine, and antifebrin; injections of atropine, morphine, and theine; electrical treatment had been employed; and among surgical procedures, blistering, nerve-stretching by elevating the limb during ether-anæsthesia, and, finally, nerve-stretching after incision and exposure. The latter operation was performed February 21, 1888. Immediately after the operation slight relief was experienced, although pain below the knee continued, and with the return of the power of motion in the limb, pain recurred as violent as ever; and had continued without intermission for about two weeks, except when the patient was under the influence of hypodermatic injections of morphine, without which he could not obtain sleep. He was then transferred to the general medical clinic. Salol being then under investigation, especially as to its analgesic properties, was prescribed tentatively in doses of about thirty to forty grains per diem. It gave relief, but not enough to warrant the hope of permanent good from its continued administration.

March 29. An injection of ten minims of a one per cent. solution of osmic acid was made deeply into the thigh in the neighborhood of the point of emergence of the sciatic nerve, just above the cicatrix of the incision for nerve-stretching. On each of the two succeeding days, fifteen minims were injected. Improvement now began to be manifested, although the pain continued to disturb sleep. Tri-weekly injections of twenty minims each were made during the next two weeks; a pill of morphine, belladonna, and quinine being given when necessary to produce sleep.

April 11. The patient was improved sufficiently to sleep without the pill.

19th. Improvement had steadily progressed, so that only a cane was used instead of crutches for walking. An injection of twenty minims was made higher in the buttock near the sciatic notch, pain being felt more especially at that point. Patient discharged from hospital.

May 17. The patient returned, stating that he still had pain, coming on at twelve or one o'clock at night and lasting until morning. He was free from pain during the day and could walk readily with the aid of a cane. An injection of thirty minims was made at the same point as previous injection.

January 1, 1889. The patient being sent for, reports that after the last injection he was so sore that he could not sleep that night. The soreness gradually abated, and two weeks later he was able to sleep without interruption during the whole night. Since then he has had no pain of any account. There is some weakness of the leg below the knee, and some improvement in the movement of the foot, but not enough to interfere with locomotion with the aid of a cane. He considers himself well.

DR. J. MADISON TAYLOR then called attention to

SOME POINTS IN THE TREATMENT OF SCIATIC NEURITIS. MASSAGE AND INUNCTION WITH A GLASS ROD.

The remarks were mainly intended to call attention to a simple device which he has used with success in the treatment of sciatic neuritis.

Probably the best treatment for sciatica is absolute rest. This, coupled with the use of continued cold, with galvanism, the repeated use of the actual cautery, or blisters, usually does much good. But oftentimes more is needed, in the shape of regulated exercise, passive exercise of the affected limb; in short, overstretching of the nerve by forced extension and flexion by a skilled manipulator, deep massage, and the like. These last

seem often to do as much or more than the more radical measures, but require the services of an experienced assistant, which many cannot afford.

A year or two ago a patient, suffering from an obstinate form of syphilis, which resisted treatment at the best hands in this country, went abroad and got practically well in the hands of a clever physician in Germany, by the use of our ancient ally mercurial ointment, applied in a very novel and effective manner. This consisted of a glass rod, the size of a section of broom-handle, two feet long, on which the ointment was smeared, and thence slowly and firmly rubbed into the skin. This combined the inunctions, which could thus be made very thorough and systematic, with deep massage of the tissues. It certainly seemed to effect a more thorough introduction of the drug into the circulation, for the ointment was thus made to disappear entirely into the skin. The firm, slow pressure thus exerted must have an immensely stimulating effect on the muscles, nerve sheaths, etc., as well as on the absorbents, and is of itself an excellent tonic. This method he has not yet been able to test thoroughly in cases of syphilis, but he confidently recommends it as offering great possibilities of rapidly impressing the system with mercury.

Having a patient suffering from chronic sciatic neuritis, on whom the skill of several specialists had been wrought in vain, he determined to apply this same method of treatment. He used an ointment of mercury, belladonna, and iodine, applied on a glass rod, for fifteen minutes at a time. Very prompt relief from pain was felt. Later he resorted to the use of the rod without the ointment, and with apparently equally good results. In a short time, two or three weeks, his case was practically cured. Since then he has used this method in many cases, usually in the hands of the patient himself—a most convenient plan. Its use is followed by a marked sensation of warmth and comfort. In one case, that of a gentleman who was obliged frequently to ride on horseback to his business out of town, the pain in both legs became intense at three or four o'clock in the morning, keeping him awake thereafter. Nothing so relieved this as ten minutes' deep massage with the rod. In a month pain which had resisted remedies for a year had gone.

Dr. Charles K. Mills did not think he had exhausted all the remedies known to our art in the treatment of the case reported by Dr. Cohen; but he remembered that the patient was treated by various methods, medicinal and otherwise. This was one of several cases in which he employed hypodermatic injections of theine. He believed that this patient received a large number of these injections. His success with this measure had been varying. In a few cases the patients had been benefited, but in the case reported to-night, and in others, the relief has been only temporary. The treatment of sciatica, like the treatment of chorea or rheumatism, is a subject about which we might talk for a long time simply enumerating the remedies that have been used. In his own practice he had a method of treating sciatica which, while it might not be scientific, was practical. He divided his cases into recent cases, old cases, and intermediate cases. Recent cases would commonly yield to such remedies as salicylate of sodium, oil of gaultheria, and analogous drugs, associating with this treatment the hypodermatic injection of morphia and atropia, and sometimes of theine. For the old cases he used some very old remedies, and often with greater success than some of the newer remedies. He had used turpentine with success after the method first recommended by Thomas King Chambers. He also used Donovan's solution in fair doses; also iodide of potassium and colchicum. In these cases he nearly always associated with the foregoing agents the use of cod-liver oil, massage, and electricity. On the whole, he got as good results from this treatment as from any other. He had also used the Adamkiewicz electrode, by means of which chloroform is applied externally and electrically. This treatment had proved successful in a few instances. All, of course, have used counter-irritation. The use of the hot iron certainly acted better than any other form of counter-irritation. So far as osmic acid is concerned, he had had very little experience. He had used nerve-stretching by the method without cutting, and in a few cases by cutting, but never with any marked success.

The case reported to-night is valuable and interesting, but the report of a single brilliant success with a remedy like osmic acid in a case like this, does not carry the full force of conviction as to its great value. The disease had existed for a very long time, it is true, and it finally yielded apparently to this agent, not long after surgical and other procedures had been used.

Dr. James Hendrie Lloyd last year treated a case of sciatica which he cured in eight months, and he wished to refer especially to what seemed to do the most good. He first applied the hot iron very thoroughly; he burned four holes along the course of the sciatic nerve. This afforded some relief, but did not cure the case. The man was sick for at least six months after this application. During this time he employed the usual remedies, salicylate of sodium in large doses, antipyrin, etc. He packed the leg in flowers of sulphur for a time without benefit. He then had an exacerbation of the pain and had to employ large doses of morphia hypodermatically. The injections were made deep into the muscles, but he must have used a syringe which was not aseptic, for abscesses formed. These were quite troublesome and burrowed through the muscles of the buttock, but the effect on the sciatica was very marked. Improvement began as soon as there was a free escape of pus. He supposed that this acted simply as another form of counter-irritant. He, however, did not recommend this as a method of treatment.

Speaking of one case not establishing a principle reminded him that in the first year of his practice he saw an obstinate case of sciatica in the person of his preceptor. After it had continued six months, the application of the hot iron in exactly the same manner as he employed it in the case referred to, was attended with brilliant success. From the time that he came out of the ether he never had a recurrence of the pain, and for the remaining two or three years of his life he had no return of the trouble.

Last year he saw removed, at the Philadelphia Hospital, a sciatic nerve which evidently had been the seat of a good deal of inflammation. He could not help thinking that the proper way to treat such a case would be to cut down with antiseptic precautions and open the sheath of the nerve. He believed that if we could be positive that the nerve is in that condition, that would

be *the* method which would give the best results. This would be only following out the old-fashioned practice, obtained from the Chinese, of puncturing the sheath of the nerve with gold needles. He did not believe that the rubbing of ointments on the skin, separated from the nerve by thick layers of muscles, could influence the inflammatory action. He was sceptical in regard to all such remedies.

DR. F. X. DERCUM said that there was one practical point of importance in regard to the use of the actual cautery: that is, that the burn should be superficial, not deep. We want to impress the nerve-endings, not to make holes, and to heal up the burns as rapidly as possible. After applying the hot iron dress the burn antiseptically and allow it to heal. It is, he thinks, the *repeated* burnings that accomplish the good. His ordinary method in the treatment of sciatica is first to use the salicylates. If ordinary doses do not give a good result, then to give as large a dose as the patient can bear. The suggestion of Dr. Lloyd in regard to opening the sheath, he considered to be a valuable one. If there is inflammation, incision of the sheath would allow the effusion to escape. Even if it did not accomplish good in this way, it might so alter the nutrition of the nerve that benefit would ensue.

DR. S. WEIR MITCHELL desired to make a few remarks upon this disease, which is so often quite easy to treat, and, again, so excessively difficult. It has a host of remedies. It had been his own fortune to see in hospital practice an enormous number of cases of sciatica, and he really thought he had done something toward improving the methods of treatment in old and obstinate cases. It is probable that a large number of slighter cases are of rheumatic origin, but when this condition endures for a long time, or there is a primary traumatic cause, it is pretty sure to end in inflammation of the sheath, or of the nerve track, or of both, with more or less effusion within the sheath. Much of this opinion may seem to be mere guess-work, for the opportunities of seeing the living nerve are rare. He had, however, in two cases during the war, seen the nerve cut down upon for the relief of serious traumatic neuralgia. In both there was a considerable amount of serum within the nerve sheath. In one, as he remembered, the nerve itself was distinctly swollen and inflamed. In both these instances four or more inches of nerve were exposed, and in both cases the results of the operation were excellent.

In speaking of this matter of the treatment of sciatica, he desired to say that if the case has lasted long, or has not, and is serious or slight, of course he need hardly refer to the need of the most careful attention to the constitutional condition of the patient; nor need he go into the consideration of the anæmic, scorbutic, or gouty states, which require and reward prompt treatment by internal remedies. He might say, however, that if these matters having been duty considered, in ordinary instances of sciatica, massage alone is often competent to do the rest. What Dr. Taylor had said in this connection is of interest. This mode of treating by massage is what the French call *effleurage*, and not deep kneading. A roller of glass would be a good instrument for making this form of impression on the nerves. It is simple, and anybody could be taught to use it.

In more severe cases the cautery is his favorite remedy. He was perfectly at one with Dr. Dercum in reference to the manner of using it. It should be used so as not to destroy the skin, which ought to be touched lightly three or four times in places along the track of the nerve. This may be repeated every three or four days until a cure is effected. Such burns scarcely require any dressing. In children, or in nervous people, the previous application of ice, or of ice and salt, will prevent any immediate pain. But as regards this and all local means of treating this disorder he felt quite sure that they are most successful when the patient is kept at rest in bed.

As to nerve-stretching, he had had it done for sciatica three times, and he had seen three cases in which it had been done, so that his whole experience rests upon six cases. He thought he had never seen a case cured by this means. He did not say that it did not relieve for a time, for it did. But he might also add that in the last few years he had seen cases of this disease treated by nerve-stretching with failure of relief, and had afterward seen them cured by means which might have been used first. Strong extension of the muscles, such as involves more or less stretching of the nerves, he thought was of great value in certain spastic spinal affections. But he had never had any luck with this treatment of sciatica.

He would like again and again to repeat that in severe cases rest is an imperative need. By this he did not mean merely remaining in bed, but the use of methods which may or may not be altogether his own (that is a matter of indifference), but which he had never seen elsewhere described, and which are now often used in the Infirmary by himself and his colleagues. These consist in placing the patient who has this neuralgia in bed and putting on him an old-fashioned thigh-fracture splint, insisting upon its being worn night and day, so that it is impossible for him to bend his leg. The result of this absolute rest is, in many cases, quite remarkable. Nor does this means forbid the use of other agencies, notably the cautery, or low temperature, or of other measures which may be allowable.

Another measure which he did not know to have been used by any one than himself is the *persistent* application of ice along the nerve track. This consists in applying ice-bags along the whole track of the main nerve *in connection with the splint;* that is to say, these bags are applied from the sciatic notch to below the knee. They are kept on day and night. In one case they were used as long as three weeks, with triumphant results.

He had made some investigations in regard to the temperature obtained by these applications, and at a later date he would make a report on this, considering it to be a subject worthy of further investigation. He had used bags filled with ice, and had had ice-water circulating through the bag. He had found that, by the use of different saline solutions with ice, it was possible to secure certain definite temperatures in the skin under the bags.

DR. WHARTON SINKLER desired to call attention to one method which had not been spoken of. That is the method of acupuncture by the German apparatus called Baumscheidtmus, consisting of a number of needles which are driven into the skin in the course of the nerve and some counter-irritant oil rubbed in. He had cured one case of most obstinate and violent sciatica by this means, and the patient remained well for a number of years. In this case, however, it is possible that the result was influenced by the sloughing which occurred at the point of

puncture. In another case, in which sloughing did not occur, a cure was also effected.

Dr. S. Solis-Cohen was aware that one case does not establish a general rule, and on that account simply reported this case without comment. Osmic acid, however, is not an untried remedy. There are very many cases of its use on record, principally during the last five or six years. He had used it in some twelve or fifteen cases, but only two were in private practice, and the notes in regard to the others are not at present accessible. His impression is that the result was satisfactory in about one-half of the cases. The German physician who first investigated this method reported upward of forty or fifty cases, and found that the results were best in the oldest cases. It was useless in the acute cases. Some experiments on animals were reported, showing that a definite alteration in the nerve cells, similar to that observed in histological preparations treated with the same agent, followed the injection of the remedy. It is probable that conduction is interfered with. He did not know how else we can explain the good result. He agreed with the speakers who consider internal remedies, except where there is a constitutional or diathetic fault, as useless, except for palliation. Where the sciatica depends upon gout, or rheumatism, or anæmia, of course, salicylates, iron, arsenic, etc., as indicated, will often effect a cure, or greatly assist recovery. The value of iron specially needs emphasis, not only in anæmic but certain rheumatic conditions. Among remedies not mentioned, he had seen good results from the deep injection of chloroform. He had also occasionally seen temporary good results from the deep injection of atropine and morphine, in cases where the injection of morphine alone was without curative effect. The long list of agents and methods, each of which has been useful in some instances, shows there is no single treatment; but he believed that osmic acid, deeply injected near the seat of greatest pain, is among the remedies eminently worthy of consideration in unyielding cases such as that reported.

Dr. J. Madison Taylor said that there is an anatomical point which he did not see credited with the influence which it deserves in determining the frequent occurrence of neuritis of the great sciatic near its exit from the notch. The nerve is very exposed just here, and it suffers direct compression by the action of several powerful muscles which run directly transverse to its course. The pyriformis alone acts as almost a constricting band in front, opposed by the obturator interni and Gemelli beneath. In whatsoever attitude the body assumes when any of these muscles are put in tension, there is strong compression exerted on these tender fibres. Hence, when inflammatory action occurs in the nerve or its sheath, it is brought to a focus here, the circulation is interfered with, and the smallest muscular movements cause pain and irritation. It is seldom granted us to see this organ in its earlier subacute or chronic condition of engorgement and thickening, but it is pretty certain we should find a red, swollen organ, with a jelly-like or serofibrinous exudate, crowding the sheath space, with here and there bloody extravasations. Now, next to the actual removal of this diseased section, as suggested by Dr. Lloyd, but not likely to be yet generally adopted, to his mind, comes the gentle systematic compressing action by such means as he had suggested, which aids in breaking up old adhesions, and emptying out the engorged sheath, and such other results as aid a reëstablishing of the normal elasticity of the parts. This massage does, but no hand can beat the power which this simple agent possesses, nor does the percutor of Mr. Mortimer Granville, so excellent in its results, do it any better, and not nearly so cheaply.

Dr. J. Chalmers Da Costa reported

FOUR CASES OF COCAINE DELIRIUM,

two of which occurred in his office practice, and two were observed in the surgical out-patient department of the Jefferson College Hospital, and the latter he is enabled to report by the courtesy of Dr. Horwitz, the department chief.

Case I. — Man, twenty-five years of age, of nervous temperament, and addicted to the excessive use of alcohol. He had a stricture of the urethra, and had been for some time under treatment, but as the passage of instruments occasioned considerable pain, it was determined that cocaine should be employed.

He was handed a syringe containing ♏ xxx of a four per cent. solution, and told to throw it into the urethra. In a moment, on turning, he discovered him still seated on the edge of the sofa, one hand grasping the penis, the other the syringe, but pale and immobile as a statue; he spoke to him, but he made no answer, and when he touched him he fell over. He did not seem to breathe; the pulse at the wrist was imperceptible, the pupils were widely dilated, the lips were pale, the face pallid and bathed with sweat; there were muscular resolution and complete unconsciousness. In about fifteen seconds breathing began, and the pulse reappeared. The pulse beat fifty to the minute, was small, and of high tension. The respirations were shallow and slow. The pupils were moderately dilated, and did not respond to light. Muscular resolution and unconsciousness were complete. Conjunctival reflex was abolished. The extremities were icy-cold. There was entire insensibility to pain. The body was drenched with sweat. After several minutes, the face showed signs of venous congestion, the facial muscles twitched convulsively, the arms and legs were worked in a violent and irregular manner, and the patient tossed about on the sofa. The conjunctival reflex returned, but there was still analgesia. He soon began to talk incoherently, to laugh, shout, and sing, put paid no attention to words, or to being roughly shaken, and seemed entirely oblivious to his surroundings. He obviously had hallucinations of sight and hearing of an agreeable nature. The pulse was now rapid, weak, and irregular. The respiration shallow, frequent, and jerking.

This delirium gradually passed away; he would answer when spoken to, but could not maintain a thread of conversation, and when left to himself was concentrated on his own ideas, which flowed in a torrent, now grave, now gay, now majestic, now amusing. This condition was one of intellectual brilliancy. He quoted poetry, oratory, and philosophy (being a particularly well educated man, and a writer himself of some attainments). He gave portions of "Locksley Hall," with excellent effect, and wept as he recited Keats's "Ode to a Nightingale." When told that he had fainted while grasping his penis, and asked what would have been said by his friends had he died in that attitude, he responded, "The ruling passion is strong in death." He said he felt "gloriously

happy," and that "a drowsy numbness filled his veins." Gradually he became quiet, and about one hour after the onset of the symptoms passed into an apparently natural sleep from which he awoke in two hours, feeling languid and somewhat giddy; complaining of headache and numbness of the extremities, dryness of the mouth, dimness of vision, and an intense desire to make water.

He remembered having begun to take the injection, but could recollect nothing more until he had reached the stage which he denominated a "poet's dream." In this stage, he says, his happiness was complete; he felt no care, took no note of time, experienced no surprise as to his situation, and was occupied with poetic thoughts, dressed in splendid imagery.

He states that this mental condition was apparently identical with that occasioned in him by large experimental doses of hashish.

This gentleman, being of an experimental turn of mind, repeated the injection one night, with the result of alarming his family to a terrible extent. The family physician, who was sent for, expressed a strong and angry suspicion that alcohol was the whole trouble. The after-effects of this dose were decidedly unpleasant, and lasted many hours; being chiefly great prostration, numbness of the extremities, dry mouth, and dimness of vision.

Case II.—Man, twenty years of age, brother of the preceding, of similar habits and temperament. Had been for some time under my care for urethral stricture. On his solicitation, ♏ xv of a three per cent. solution of cocaine were injected into the urethra. Several bougies were passed without giving any pain. Some five minutes after the injection it was observed that his attention was withdrawn from the operation, and that he gave no answer when spoken to. The face was pale and covered with sweat, the pupils were moderately dilated, the pulse slow and of high tension, the respirations rapid, jerking, and irregular. Conjunctival reflex was not abolished, and on testing it he began to roll around, to toss his extremities, to shout and swear. He cried out that he could not breathe; he had hallucinations of sight, brushing bugs off of his coat; and illusions of personality, thinking I was his brother.

He arose from the couch, staggered like a drunken man, and incoördinately adjusted his garments. His face was now flushed, and his pupils of normal size. He staggered about the office, upset chairs, aimed blows at me, and, with indistinct articulation, declared that I wanted to kill him. He insisted on going out, was with great difficulty got into a carriage, taken home, and put to bed, where he finally went to sleep, under sodii brom. and morphia. He awoke in the morning feeling as if he had been "on a tear," and dimly remembering that he had abused me violently, for which he was very penitent. He remembered coming to my office, but had no memory of taking the injection, or of being operated upon.

Case III.—Man, twenty-two years of age. Also a drinker. Came to the hospital to be operated upon for phimosis. 10 ♏ of a four per cent. solution of cocaine were thrown into the prepuce by means of a hypodermatic syringe. The operation was not entirely painless. About fifteen minutes after the injection he became very pale, and tetanically rigid, like a person in the first stage of an epileptic fit. The pupils were dilated, face was pale and covered with sweat, extremities cold, and he was unconscious. After a few seconds he tossed his arms, body, legs, and head, in a manner suggestive of the progressive movements of hystero-epilepsy. The pulse was rapid (120), weak, and irregular. The respirations shallow and rapid. The reflexes were dulled, but not abolished. Sensibility was diminished, but not destroyed. He talked rapidly, inarticulately, and incoherently, prayed, swore, threatened, and tried to get up. In about twenty minutes he became quiet, was put to bed in the wards, and after some hours went home. Next day felt all right.

Case IV.—Man, thirty years of age. Nervous temperament. Habits unknown. Came to the hospital for urethral stricture. Passage of instruments was productive of so much pain that 20 ♏ of a six per cent. solution of cocaine were injected into the urethra. In a few minutes he began to mutter, and to move his right hand as if sending a telegram (he was a telegraph operator). He began to talk about the message, saying it must be sent, and telegraphed with tremendous energy. His face was pale and moist, pupils of normal size and reacted to light, conjunctival and plantar reflexes present. Did not answer when spoken to, and did not feel a pin point. Respirations were rapid and shallow. Pulse was slow, and of considerable tension. This condition existed for some ten minutes, when he became conscious, and asked what was the matter. He complained of dyspnœa, and had no memory of events after the passage of the first bougie. Next morning he stated that he felt dull and heavy for a number of hours after going home, that he found great difficulty in picking up small objects (pens, pencils, etc.), and that his fingers seemed numb, and could scarcely feel objects or grasp them.

Some physicians who have seen cases similar to these have stated their belief that the symptoms were purely the result of fright; but only one of these cases showed any apprehension.

It might be considered possible that such phenomena could ensue from a condition of reflex irritation, similar to the so-called pleuritic epilepsies which occasionally result from injecting the pleural cavity with iodine or some other agent. It seems improbable, however, that this was the condition here, as previous instrumentation on three of the cases induced no reflex disturbances and a repetition of the injection in one reproduced the symptoms.

He asked if the high arterial tension, the small and usually slow pulse, the pallor, the dilated pupils, and the unconsciousness are not evidences of cerebral anæmia from vaso-motor spasm. An interesting fact of this series of cases is the exhibition of a family idiosyncrasy by the occurrence of toxic symptoms in two brothers.

He inquired if the nervous temperament and the abuse of alcohol did not render the organism particularly susceptible to the action of cocaine, and if any signs exist which would indicate to us that cocaine would be dangerous in a given case.

DR. FRANCIS X. DERCUM had repeatedly given cocaine in half-grain doses by subcutaneous injection without noticing any serious symptoms. This report is exceedingly interesting, and it is a question in his mind whether or not the locality in which the cocaine was applied had anything to do with the symptoms. The urethra is very sensitive and is intimately associated with the spinal centres. We must take this into consideration. It seemed to him that the case could hardly be considered proved unless a cross experiment was made by injecting a similar

dose of cocaine into the subcutaneous tissues of the patients whose interesting symptoms had just been detailed.

Dr. Mitchell thought that the point in regard to the location of the injection was well taken. He knew by personal experience that different methods of taking a drug produce very different effects. When he himself takes morphia by the stomach, it produces horrible vomiting and headache, but when taken hypodermatically no inconvenience is produced; but this is common knowledge. What has been here told as to the occasional effects or the apparent effects of cocaine, when used by the urethra, should lead to some examination into the matter, since it is possible that there may be peculiarities due, in certain constitutions, to local impressions made on that sensitive tube by drugs.

Dr. Lloyd asked what is the proper dose of cocaine. He was using in one case two grains daily in divided doses, so far without any apparent effect.

Dr. E. N. Brush had had more or less experience with the injection of cocaine when it was first suggested for the treatment of certain forms of melancholia with stupor. He employed it in doses of from one-half to one grain. The effect was to induce laughter in some, and a talkative state; it was only temporary and no serious symptoms were produced.

Personal experience had taught him that the effect of this drug on certain persons, even in good general health, is to render them more talkative. Last fall he used a four per cent. solution as a spray for a throat trouble, continuing the application but a few minutes. A talkative state was produced and in twenty minutes there was severe headache. He repeated the experiment on other occasions with the same result. He had had under his care a physician who, when he came to the hospital, was taking ten grains of cocaine daily. He had taken as much as thirty grains; Dr. Brush cut him down to two grains, then to one grain and then stopped it altogether. There was no disturbance. He had had in all under his care three physicians who were addicted to the use of cocaine. Two used it hypodermatically and one by the mouth. The latter took forty grains a day, according to his own statement.

Dr. J. Chalmers DaCosta said that in hastily looking over the literature he found a very wide range of variation in reference to the dosage of cocaine. Martindale states in his book on coca and cocaine, that one man took without obvious ill-effect twenty-three grains. Another took, with suicidal intent, thirty-two grains, the result being considerable prostration. Dr. Dien, of Dantzic, an ophthalmologist, injected one-tenth of a grain under the conjunctiva and produced very alarming symptoms. The dangerous dose therefore seems to be somewhere between the wide extremes of one-tenth of a grain and thirty-two grains, but exactly where it is hard to tell.

CORRESPONDENCE.

THE MEDICAL EXAMINERS' BILL.

To the Editor of The Medical News.

Sir: It would seem that the present position of the discussion over the Medical Examiners' Bill, which has unavoidably been conducted chiefly in the newspapers, calls for a word of comment in the columns of the medical press. Doubtless the arguments which led to the decision that such a bill should be introduced were cogent and convincing. Probably a large proportion of the profession approved of the general principle which underlies all such bills, but were not acquainted with the details of this particular measure. It has, however, been subjected to critical examination, during the active discussion which has sprung up over it, and the impression seems well founded that, with a slight amendment, which would make more conspicuous the good faith and intent of the bill, it was as good as any such bill could be for its purpose. This purpose was, of course, the elevation of the standard of medical education, and the improvement of the grade of medical practitioners in this State.

The notion of securing these important gains by legislative enactment is so familiar to the public and to the profession in other countries, that it might well seem strange that the evils of unlimited free trade in the production of physicians should so long have been tolerated in the United States. The improvement effected by the competition of excessively numerous schools of all kinds and grades may never be general or adequate. It is, indeed, doubtful whether the original Examiners' Bill would have been sufficient. Examinations do not educate, and there are ways of cramming for them which prevent them from being adequate tests of education. Of course, they are far better than nothing. But it is the contention of the vast majority of the community and of physicians, that the amendments incorporated in the bill would reduce the value of these provisions to a serious degree. A manly protest against these amendments was made without effect. It was made by a group of individuals who represented no medical school officially, but who personally represented all of the regular medical schools in Philadelphia. When, however, it became evident that the bill would either be defeated on final reading in the House, or would go to the Senate in an unsatisfactory shape, it was resolved by a number of these individuals after prolonged conference to urge an additional amendment in the Senate, which would again render the bill a sure means of elevating the profession, and of protecting the public.

It may seem even presumptuous to start an agitation which aims at nothing less than the establishment of compulsory four-year teaching on the part of all medical schools in this State, and of all which educate students intending to practise in this State.

But those who are in closest touch with the profession feel most strongly the rapidly growing sentiment in favor of prolonged and thoroughly practical instruction. Experience in actually conducting a three years' graded course in a large city, such as Pittsburg or Philadelphia, will convince anyone, it is believed, that the student is as inevitably overtaxed in the effort to acquire a real education in three years as he formerly was in the effort to secure superficial instruction in two years. As soon as you enter on the task of providing for each student full laboratory and hospital work in medicine, surgery, obstetrics, and the leading specialties, it is manifest that the requisite number of hours cannot be had in a three years' roster, save by overburdening the student, so that it is impossible for him to assimilate the wealth of instruction provided. Only too often his health also suffers

in the strain. Now that medical teaching is coming to be regarded from the highest standpoint, and when new and important branches, as medical jurisprudence and hygiene, demand full recognition, it is inevitable that four years' study—the lowest term allowed by any European country—must soon become the rule here also. Certainly scholarships must be founded in the interest of deserving students without sufficient means to meet the heavier expense of prolonged study. But the moment that such a course of study becomes obligatory, there will be munificent provisions for such scholarships in medicine, just as is seen in other branches of study. The overcrowding of the profession would be lessened, and the students would find such an education a practical guarantee of subsequent success.

Certainly the profits of the professors in medical schools would be reduced when this reform is effected, for although the total of fees might be larger, the heavy working expenses would cut down the net profit. But it may be hoped that the direct and indirect advantages of such positions would still attract to the practical chairs the strongest men, while the claims of the non-practical chairs for endowment would soon be answered by our communities which are showing themselves so ready to supply the actual needs of sound education.

It is believed then by those who advocate this amendment, that it would be easy so to fix the date when the full provisions of the bill should become effective as to avoid any interference with vested interests; that there is not a medical school in this State which could not establish such a four-year course with success under the operation of the proposed law; and that the true interests of the public and of the profession would be promoted by its enactment.

It is in this spirit the amendment will be proposed. It is hoped the profession throughout the State will support it.

TREPHINING THE SKULL AND TAPPING THE VENTRICLES.

To the Editor of THE MEDICAL NEWS,

SIR: I have just seen in THE MEDICAL NEWS of March 9th, under the proceedings of the Philadelphia County Medical Society, a preliminary report by Dr. W. W. Keen of a case of tapping and irrigation of the ventricles.

Since Dr. Keen believes the operation in this case was the first of the kind ever performed, I may be permitted to mention that one month previous to his operation, I performed almost the exact one, viz., that of trephining and tapping the lateral ventricle. This was on the 4th of December, 1888.

The patient was presented after operation, and the details reported to the Allegheny County Medical Society on the 19th of February last, and are published in full in the *Pittsburg Medical Review* for the current month, March. Hence, as far as pertains to Dr. Keen, I may be excused for laying claim to priority in the operation.

But I am not prepared to claim universal priority, though unable to find any previous account of the exact operation. It is, of course, well known that the lateral ventricles have been frequently tapped for hydrocephalic fluid, but so far as I could ascertain, this had always been done through the *unclosed* sutures.

I regret that I have not seen the general rules for this operation formulated by Dr. Keen, to which he refers in the above report; and, furthermore, that in casting about for similar operations to my own, at the time of preparing my paper, I omitted reference to one quite analogous by this same surgeon to which my attention was first called in an editorial on "Deeper Brain Surgery," in the *Journal of the American Medical Association* of December 8, 1888.

Respectfully yours,

SAMUEL AYRES.

PITTSBURG, PA., March 23, 1889.

POISONOUS EFFECTS OF COCAINE.

To the Editor of THE MEDICAL NEWS,

SIR: In your issue of March 9th is an extract from the *British Medical Journal* relating to the poisonous effects of cocaine, in which opium, chloral, ether, and chloroform are spoken of as the best remedies to relieve the poisonous symptoms.

I have often seen, as the result of its use on mucous membranes, pallor, giddiness, nausea, vomiting, with rapidity and weakness of the pulse, dyspnœa, or rather a sense of choking, and sometimes profuse sweating. Frequently headache has supervened, and occasionally pain in the region of the heart. In two or three cases fainting has occurred. Usually these symptoms subside of themselves within half an hour or an hour, but sometimes a part of them may continue many hours. I have seen the headache, which would otherwise have lasted several hours, promptly relieved by fifteen grains of bromide of potassium; but for the giddiness, or actual fainting, I think nothing answers so well as alcoholic stimulation.

For example: A patient, on whom grs. jss cocaine hydrochlorate, in ten per cent. solution, had been used on the Schneiderian mucous membrane, became so faint that he could not sit up, complained of pain about the heart, and passed quickly into a semi-conscious condition. Two drachms of alcohol, diluted with water, were administered by the stomach. Nearly all of the symptoms disappeared within fifteen minutes.

Second. A patient, whose nasal cavity was being anæsthetized, became giddy and soon fainted, when only about one-third the amount necessary to produce anæsthesia had been used. Two drachms of alcohol in water promptly relieved the symptoms. The application o cocaine was then renewed, and the anæsthesia and subsequent operation were completed without further inconvenience.

I think that some of the symptoms attributed to the poisonous influence of cocaine are largely due to fright, but I feel confident that the results of poisoning are better relieved by alcoholics than by other remedies.

I have seen alarming symptoms follow the application of half a grain of cocaine, in solution, to the nasal mucous membrane, but have seen other patients who experienced no inconvenience from the use of five grains in this way. However, one to one and a half grains should not be exceeded when it is possible to obtain anæsthesia with less.

E. Fletcher Ingals.

Chicago, March 22, 1889.

AUTOMATIC AMBULATION.

To the Editor of The Medical News.

Sir: The very interesting case described by Dr. Donaldson under the title "Automatic Ambulation," which he had seen in the clinic of Charcot, is not without a parallel, as the doctor supposes. The condition of the patient, in which, though seemingly rational, he was really suffering from a lapse of consciousness, is one which has been described by several writers upon epilepsy, notably Hughlings Jackson and Gowers. Formerly it was asserted that such a state of double consciousness was always a post-epileptic phenomenon. Now it is believed that it may occur as the psychical equivalent of the epileptic attack.

An interesting case, which illustrates this condition, was observed at my clinic not very long ago. A young man, a carpenter by trade, who had occasionally suffered from epileptic attacks, related the following history: He remembered having come home as usual from work on a Thursday night, and having gone to bed with his brother, with whom he always slept. The next thing which he remembers, is awaking on Friday afternoon at four o'clock, and finding himself in Bellevue Hospital. He had no recollection whatever of how he got there, and it was a surprise to him not to find himself in his own room. He learned, however, subsequently, that he had gotten up, apparently as usual, on Friday morning, after a quiet night, his brother being positive that he could not have had an epileptic attack during the night, and his family having noticed nothing unusual in his appearance or manner. He had gone to his work as usual, and had been sent by the foreman upon an errand, involving a walk of sixteen blocks, which errand he had partly carried out, as he had delivered the package at the required place. His next trace of himself is in a distant part of the city, in the shop of a plumber, with whom, it seems, he had picked a quarrel, and who turned him over to a policeman, who in turn took him to the station-house, whence he was sent to Bellevue Hospital. The police justice sent him to the hospital because he appeared to be bewildered, but not drunk, as he answered questions intelligibly, and could walk perfectly, and yet did not seem well. When he reached the hospital he was put to bed, and soon fell asleep. When the physician came to examine him soon after, he was awakened, and then was in his natural condition, and, appearing to be well, he was discharged, and came home.

There appeared to be no evidence that the boy had had a fit; his tongue was not bitten, he was not fatigued as he had been after other attacks. He was very intelligent, and took an interest in his condition, finding out the facts which have been related. There had, undoubtedly, been a total "lapse of consciousness" from Thursday night until Friday afternoon, yet during this period he had acted as if conscious, and had found his way as usual to his place of work. It seems preferable to speak of such a state as one of double consciousness, rather than as one of lapse of consciousness, though there is certainly a lapse of memory. He has had no subsequent attack to my knowledge, having been treated with bromides as for epilepsy.

A somewhat similar case has recently come under my observation in consultation, but various circumstances subsequently discovered by the attending physician led us both to decide that it was a case of malingering. I have no doubt that others have seen similar cases, though I cannot but believe that they are very rare.

Yours respectfully,

M. Allen Starr.

22 West Forty-eighth Street, New York.

NEWS ITEMS.

Convention for Revising the Pharmacopœia.—Dr. Robert Amory, President of the Convention of 1880, calls upon the several incorporated medical societies, incorporated medical colleges, incorporated colleges of pharmacy, and incorporated pharmaceutical societies throughout the United States of America, The American Medical Association, and The American Pharmaceutical Association, to elect a number of delegates, not exceeding *three*, and upon the Surgeon-General of the Army, Surgeon-General of the Navy, and the Surgeon-General of the Marine-Hospital Service to appoint, each, not exceeding *three* medical officers, to attend a General Convention for the Revision and Publication of the Pharmacopœia, to assemble in Washington, on Wednesday, May 7, 1890, at noon.

The several bodies, as well as the Medical Departments of the Army, Navy, and Marine-Hospital Service, are requested to submit the Pharmacopœia to a careful revision, and to transmit the result of their labors to the Committee of Revision at least three months before the meeting of the General Convention.

The several medical and pharmaceutical bodies are requested to transmit to the President of the Convention of 1880, the names and residences of their respective delegates, as soon as they shall have been appointed; a list of these delegates will be published for the information of the medical public, in the newspapers and medical journals in the month of March, 1890.

If any body other than those admitted in 1880 shall desire a representation in the Convention of 1890, it is suggested that the proof of incorporation, signed by the Secretary of State, of the State which shall have issued the charter, or by properly qualified public officials of the United States, be presented with the credentials of the delegation.

A blank form of certificate of appointment of delegates will be sent upon application by letter to Dr. Robert Amory, care of Dr. Edwin H. Brigham, 19 Boyleston Place, Boston, Mass.

The Philadelphia Polyclinic Course.—Dr. Thomas J. Mays will deliver his third lecture on "Pulmonary Consumption a Neurosis," on Friday evening, April 12, 1889, at

eight o'clock, in the College building of the Philadelphia Polyclinic, Broad and Lombard Streets. The profession is cordially invited.

Medical Journalism—a Protest.—The following communication, signed by several leading members of the profession, addressed to the Presidents of the Branches of the British Medical Association, has been drawn up with the view of eliciting an expression of opinion from the members of the Association:

"It is universally admitted that the *British Medical Journal* is at present ably edited, and that, while it is a great financial success, it is a repertorium of a vast amount of valuable scientific information.

"At the same time, it is believed by many members of the profession that the best interests and the honor of the Association would be greatly promoted by a change in the character of the *Journal*.

"An opinion has for several years been wisely held that the lines on which the *Journal* is now conducted, which are similar to those of proprietary journals, with anonymous articles and reviews and multifarious advertisements, are not suitable for the organ of our Association, for the sayings and doings of which our members individually are responsible.

"It is felt that the *Journal* should be a faithful exponent of the proceedings of the Association in all its departments, while presenting a record of contemporary professional work elsewhere; but that anything beyond this, whether articles, reviews, or annotations, should have the authors' signatures appended, as indicating the actual authority of the communications. The character of the advertisements also should be more carefully controlled than at present, and especially all announcements of secret remedies should be excluded.

"It may be objected that such a change in the *Journal* would involve some pecuniary loss. But our members are now so numerous that the annual subscriptions, together with income from other sources, would cover all current expenses. And it may be remarked, that our individual self-respect is a matter of higher moment than flourishing finances.

"It is proposed, in the first instance, to address the Council of the Association, requesting them to consider this important subject, and, should it be deemed necessary, to summon a special general meeting in London. But, before taking such a step, it seems essential that there should be some guarantee that the proposed reform would be favorably regarded throughout the country. And we venture to ask that you will ascertain, as soon as may be, the feeling of your Branch upon the subject, and communicate the result to the Honorary Secretaries."—*Medical Press*, Feb. 20, 1889.

Six Laparotomies Performed upon One Patient.—The *Gazetta Medica di Torino* records the case of a woman, æt. fifty, who had submitted to laparotomy upon six different occasions at the hands of Professor Franzolini. The operations were performed between June, 1879, and April, 1887. The first was in consequence of fibro-cystic disease of the uterus. A triumph of surgery such as this, we may well believe, is without precedent, and the most satisfactory part of the case is that the patient has, since the last operation, been in the enjoyment of good health. So does she deserve her reward!—*Medical Press*, March 13, 1889.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 19 TO APRIL 1, 1889.

By direction of the Secretary of War, the leave of absence granted RICHARD C. NEWTON, *Captain and Assistant Surgeon*, in S. O. 272, November 21, 1888, is extended to include May 22, 1889.—Par. 17, *S. O. 64, A. G. O., Washington*, March 19, 1889.

The resignation of RICHARD C. NEWTON, *Captain and Assistant Surgeon*, has been accepted by the President, to take effect May 22, 1889.—Par. 18, *S. O. 64, A. G. O., Washington*, March 19, 1889.

Commanding Officer at Los Angeles, California, reports the death of R. H. ALEXANDER, *Lieutenant-Colonel and Surgeon* (U. S. Army) at 11.50 this morning, March 29, 1889. (Telegram.)

BARNETT, RICHARDS, *Assistant Surgeon* (U. S. Army).—Died, March 31, 1889, at Fort Riley, Kansas.

MAUS, LOUIS M., *Captain and Assistant Surgeon* (Fort Schuyler, New York Harbor).—Will proceed to Camp S. B. Luce, Fisher's Island, New York, with Battery "K," Fifth United States Artillery, and report to the camp commander for a tour of rifle practice.—Par. 10, *S. O. 158, Headquarters Division of the Atlantic, Governor's Island, New York City.*

BALL, R. B., *Assistant Surgeon.*—Ordered to Fort Riley, Kansas, for duty.—*S. O. 36, Headquarters Department of the Missouri.*

JOHNSON, R. W., *Assistant Surgeon.*—Reports departure for Whipple Barracks, Arizona Territory, March 25, 1889.

Atlanta Barracks, Georgia, established by *G. O. 28, A. G. O.*, March 21, 1889..

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY, FOR THE TWO WEEKS ENDING MARCH 30, 1889.

FARWELL, W. G., *Surgeon.*—Detached from the Receiving-ship "Franklin," April 1, and ordered to the Naval Hospital, Norfolk, Virginia.

MARMION, R. A., *Surgeon.*—Ordered to the Receiving-ship "Franklin."

FEREBEE, N. McP., *Surgeon.*—Detached from the Naval Hospital, Norfolk, Virginia, and placed on waiting orders.

BERRYHILL, THOMAS A., *Assistant Surgeon.*—Detached from the Naval Academy, Annapolis, Maryland, and ordered to the Naval Hospital, New York.

HEFFENGER, A. C, *Passed Assistant Surgeon.*—Ordered to appear before the Retiring Board, Washington, D. C.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE FIVE WEEKS ENDING MARCH 30, 1889.

MAGRUDER, G. M., *Assistant Surgeon.*—To report to the Supervising Surgeon-General, in person, for temporary duty, March 1 and 23, 1889.

KINYOUN, J. J., *Assistant Surgeon.*—Relieved from duty at Baltimore, Maryland, to rejoin station at New York City, March 18, 1889.

PERRY, J. C., *Assistant Surgeon.*—Commissioned by the President, March 21, 1889. Ordered to the Marine Hospital, Mobile, Alabama, for temporary duty, March 22, 1889.

SMITH, A. C., *Assistant Surgeon.*—Commissioned by the President, March 21, 1889. Ordered to Marine Hospital, Louisville, Kentucky, March 22, 1889, for temporary duty.

BAILHACHE, P. H., *Surgeon.*—Relieved from duty at Philadelphia, Pa., to assume charge of the Service at San Francisco, California, March 28, 1889.

SAWTELLE, H. W., *Surgeon.*—When relieved at San Francisco, Cal., to assume charge of the Service at Portland, Me., March 28, 1889.

BANKS, C. E., *Passed Assistant Surgeon.*—When relieved at Portland, Me., to assume charge of the Service at Vineyard Haven, Mass., March 28, 1889.

AMES, R. P. M., *Passed Assistant Surgeon.*—When relieved at Vineyard Haven, Mass., to assume temporary charge of the Service at Philadelphia, Pa., March 28, 1889.

MAGRUDER, G. M., *Assistant Surgeon.*—When relieved at Louisville, Ky., to proceed to Memphis, Tenn., for temporary duty, March 28, 1889.

STONER, J. B, *Assistant Surgeon.*—To proceed to Pittsburg, Pa., for temporary duty, March 28, 1889.

VOL. LIV. SATURDAY, APRIL 13, 1889. No. 15.

ORIGINAL LECTURES.

ON PHAGOCYTES.

An Address
before the Alumni Association of Bellevue Hospital, New York, delivered April 3, 1889.

BY WILLIAM OSLER, M.D.,
PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA.

THERE are in the body groups of tissues possessing cells, which either normally display amœboid changes, or are capable, under certain conditions, of assuming them. By amœboid properties we mean not only the capability of free movement, but the possession of a power which enables a cell to take foreign particles into its interior. Tissues containing such cells are derived from the mesoderm, the type of which, phylogenetically, is a free wandering cell. (Minot.) In the development of this layer epithelial and non-epithelial portions may be distinguished. For the former Minot has suggested the term mesothelium, and the latter His calls mesenchym. The distinction between the two is, however, largely artificial, as the epithelium may be, and in places is, in development changed into connective tissue. And, thirdly, there are in the mesoderm, at all stages of its development, certain cells which are free and independent—mesamœboids (Minot), and which persist subsequently as leucocytes.

These mesodermic cells in the adult body, which are capable either of free amœboid movements, or of taking up into their protoplasm solid particles of various sorts, are met with:

(1) As the colorless corpuscles of blood and mucus.

(2) The connective-tissue cells, free and fixed, within the connective tissue proper, or forming the supporting framework of the solid organs.

(3) Cells of the spleen, bone, marrow, and lymph glands.

(4) The vascular and lymphatic endothelium.

(5) The alveolar epithelium of the lungs.

All of these cells possess, in a greater or less degree, the power of taking solid particles into their interior, virtually, as we say, of eating them.

On account of the possession of this property, Metschnikoff has suggested for these groups of cells the term *phagocytes*, as expressive of their most distinctive feature, and for the process in general the term phagocytosis.

He regards this function as a property handed down from the primitive unicellular organism, and traces in an interesting manner the evolution of cells possessing it throughout the animal kingdom; attempting to show a genetic relation, physiologically at least, between the free living rhizopods and the cells of the middle germinal layer of the higher animals. Not a little of the attractiveness of Metschnikoff's views is derived from the glamor of evolution thrown over them by thus attributing the retention in certain cells of an atavic property in the highest degree useful to the organism.

I shall consider first the action of these phagocytes as normal physiological factors in the work of the body; and, secondly, take up the theory that these bodies play an essential *rôle* in the protection of the organism from the invasion of specific germs.

And, first, two illustrations from comparative physiology to indicate the important part assigned to phagocytes in certain transformations which animals undergo. In the development of the frog, the removal of the tail of the tadpole, and of the gills, by gradual atrophy, is effected, according to Metschnikoff, by the activity of the amœboid cells. At a time when the hind legs begin to bud, the leucocytes migrate into the tail, and by their phagocytic action remove the tissue, fragments of which, as muscle, bits of nerve fibres, etc., may be seen in the interior of their protoplasm. The gills are absorbed by an identical process. In the transformation of the larva into the fly, Kowalewsky[1] has shown that the large masses of muscle tissues, so abundant in the larva, and other parts unnecessary in the matured condition, are removed by the activity of the phagocytes.

It has long been known that foreign bodies, such as ligatures, portions of dead bone, and other substances, may be completely removed by leucocytes. Interesting as is this, and bearing directly upon the question, I propose to limit myself entirely to the consideration of the two aspects above referred to.

Nowhere in the body do we have such a facility for studying the action of phagocytes as in the organs of respiration, in which, with the cilia of the bronchial mucosa, they share in the work of cleansing the air-passages; and of these two important agencies it is hard to say which plays the more important part in the expulsion of those particles of foreign matter which, in cities at least, we constantly inhale. There are several groups of cells engaged in this work: The ordinary mucus corpuscles; the alveolar epithelium; the connective tissue elements of the pulmonary stroma, and the leucocytes of the lymph tissue in the bronchial, tracheal, mediastinal glands.

The mucus corpuscles, which in health are derived largely from the muciparous glands, and in inflammatory states from the general bronchial mucosa, are actively concerned in attacking the dust which reaches, in ordinary inspiration, as far at least as the medium-sized tubes.

The examination of the morning sputa of a cigarette-smoker, or of a person who has been exposed to a dusty atmosphere, shows very clearly that no small proportion of the carbon grains is included within protoplasm. The free granules are abundant, but almost every leucocyte has its little load which it has picked up on its road from the finer tubes to the trachea. I have always thought this represented a neat bit of economy of labor, as there

[1] Zeitschrift für wissenschaftliche Zoölogie, Bd. 45.

can be no question that it is easier for the cilia to sweep half a dozen angular particles, when enclosed in a cell, than to work at the same when free. In all probability, the finer particles which fall upon the tracheal or the bronchial membranes are gotten rid of almost entirely by cells and cilia. There does not appear to be, to any great extent, penetration of pigment granules between the ciliated epithelium. It is unusual to see beneath the tracheal mucosa any collection of carbon grains. We do meet with it in the submucous bronchial tissue, but the active vibratile lining seems to afford a tolerably sure protection. The lymph vessels open on the surface in the pseudo-stomata, and in the experimental work of Arnold[1] and others, leucocytes carrying black grains have been seen in the submucous lymph vessels; yet the process does not seem to go on to any great degree.

The particles which reach the air cells find no active current to sweep them from the spots on which they fall. It is possible to conceive, under certain conditions, of the air cells gradually filling, were it not for the activity of phagocytes, derived largely from the alveolar epithelium, which stands, as it were, at the gateway of the lymphatic circulation.

The cells lining the air cells, seen, for instance by scraping gently the cut surface of an œdematous lung, look as flattened, desiccated, and lifeless as do the scales of the scarf skin. But appearances are deceptive in this case, and the protoplasm of these cells is not only active but probably varies much in shape with the distention or contraction of the alveoli. When in contact with liquids and in pathological conditions, they change so much in form that I find it often a difficult lesson to teach students familiar with normal histology only, to recognize in the large, swollen ovoid cells so common in sputa, alveolar epithelium. Moreover, from the rapid way in which they may be desquamated, there must be ample provision for their rapid restitution. How far in a normal state these cells take part in the work of cleansing the lungs, is not yet definitely settled. In the young, they do not often appear in the sputa, except when there are indications of catarrhal changes, but, in the adult, their presence is very common. It is rare to see one in the sputa of a hospital patient, which has not brought with it a load of carbon, all of which may not have been derived from the air cells, as these bodies can undergo amœboid changes, and, like the leucocytes, are probably not above picking up a grain or two in their course toward the larynx. In cases of bronchial catarrh, and in phthisis, these pigmented cells of the alveoli may be very abundant, producing the blackish streaks which may be seen with the naked eye. When these cells have undergone the myelin degeneration they seem no longer capable of performing scavenger work.

In coal-miners, or even in stokers and coal-heavers, these pigment-laden cells may be extraordinarily abundant. It is not only when the patient comes direct from the mines, or from the coal-yards, but the old *poitrinaires* which haunt in such numbers our city hospitals, expectorate for months, or even longer, sputa containing the pigment-laden alveolar cells, staining the entire expectoration. So persistent may this be that the process may be regarded, not simply as an extrusion of the daily dole of carbon, but as a definite excretion, if we may so use the term, of particles which have been stored up in pulmonary parenchyma.

A certain proportion of the inhaled dust particles escapes the mucus cells and the alveolar epithelium and penetrates the substance of the lung, entering at the *kitt-substanz* between the cells, or through the pseudo-stomata existing in the alveolar wall. The particles of coal-dust have such sharp angles that we may suppose them capable of mechanically lacerating the delicate alveolar cells.

In dwellers in the country, as well as in wild animals, breathing an air comparatively pure, the cilia and the phagocytes in the air-passages appear quite able to prevent access of the carbon grains to the lung tissue; whereas in the dwellers in the cities, and in animals kept in confinement, the impurities in the air are so abundant that these agents are insufficient, and sooner or later the grains penetrate the air cells, aided, no doubt by the movements of inspiration and expiration; and we have the well-known marbled or carbonized organs which we see every day upon the post-mortem table.

When the particles reach the lymph spaces, the fixed and free connective tissue cells of the stroma join actively in the work. On section we see in the alveolar septa large numbers of round protoplasmic bodies, two or three times the size of colorless blood-corpuscles, which are usually packed full of dark grains. A certain proportion is seen within the ordinary connective tissue corpuscles, and, in addition, there are, in variable numbers, ordinary leucocytes. But even these forces are insufficient to meet the constantly advancing stream of dust particles. The destiny of those which escape the phagocytes in the alveolar stroma has been accurately followed in the investigations of Arnold and others.[1] Entering the lymph stream they are carried first into the lymph nodules, which, in the lungs surround the bronchi and bloodvessels, and a large number becomes fixed in the cells of the follicular cords or are permanently embedded in the stroma.

As they pass along the lymph channels into the interlobular septa beneath the pleura, a still further number lodge, and become permanently enclosed in the stroma cells, and, finally, the remnant pass into the larger lymph channels and ultimately lodge in the bronchial and tracheal glands. Here the lymph and stroma cells of the follicular cords dispose of them permanently. That this is effected in great part by the phagocytes is, I think, unquestioned. A scraping from any moderately pigmented lymph gland shows that the chief part of its carbon load is warehoused (so to speak) in protoplasm, the granules lie for the most part imbedded free in a connective tissue matrix. Here the struggle is practically over, and though not a victory, yet the compromise which has been made is the best which could possibly be effected. The sharp irritating particles have been placed in position in which they could do the least harm, and, though not expelled, have been safely imprisoned.

Once in the lymph glands of the bronchi, it is thought they never reach the general circulation, but it has been shown of late years, that under certain circumstances the carbon particles may pass the bronchial filters and spread far and wide throughout the system. Soyka's remark-

[1] Untersuchungen über Staubinhalation und Staubmetastase. Leipzig, 1885.

[1] Vide recent work of Fleiner. Virchow's Archiv, Bd. cxii.

able case in which undoubted coal particles were found in the tissue of the spleen and of the liver illustrates what really may occur. Weigert[1] in particular has called attention to the frequency with which in the spleen and in the liver carbonization of the connective tissue occurs. He states that it results whenever densely pigmented bronchial glands form close adhesion to the pulmonary veins, through the walls of which the carbon particles pass and so reach the general circulation. I would not call the condition common, but I have seen at least three instances at the Philadelphia Hospital in which the irregularly distributed pigment in the spleen and in the liver (in the latter chiefly along the portal canals) was undoubtedly of extraneous, not of hæmic origin.

The steps in this process described may be followed in the lungs of any town dweller, but to see in perfection the remarkable activity of the pulmonary phagocytes, one must study the early stages of anthracosis, particularly in those exceptional cases which we see occasionally when a miner has been killed by accident or dies of acute disease. It is not, I think, too much to say that the larger part of the pigment contained in lungs almost, if not quite, black, is enclosed in protoplasmic cells. Here too the invading particles are more formidable and not so readily dealt with; yet one frequently finds long irregular bits completely encircled by a film of protoplasm which the phagocyte has stretched to the utmost, just as we may see an amœba extend along the whole length of one of the short rod-like diatoms.

I know of nothing which illustrates better the remarkable amœboid properties of human protoplasm than a slide prepared from the scraping of such a lung, or of the black juice pressed therefrom. Scarcely a leucocyte can be seen which has not been at work, and many of the larger cells have the protoplasm stuffed to the full with carbon grains. Only in the work of the pond amœbæ preying amongst desmids, diatoms, and algæ can we see such better illustrations of active work. There is, of course, this difference, that the amœba eats to live, and so far as I know never loads its protoplasm with useless stuff. The body phagocytes take anything, never exercising selective powers. The particles which gain entrance to the lungs may be far too large for a single phagocyte to attack successfully. I have sketches showing rod-like particles, the ends of which appear enclosed in protoplasm of a dumb-bell shape; while in one instance not only were the ends enclosed, but the central portion was completely enveloped by the third leucocyte.

A physiological process in which phagocytes play a leading *rôle*, is the removal and digintegration of the red blood-corpuscles which have lived their life and are no longer fit for work. The cells containing the red blood-corpuscles, which are found in the bone marrow and in the spleen, however much opinion may differ as to their mode of origin, cannot, I think, be regarded in any other light than as phagocytic elements with this definite function. They exist normally in the red marrow, and in the spleen, and we may recognize (1) cells which appear to be, from their size and shape, elements of the pulp and (2) cells which belong to, or are derived from the endothelium of the capillaries, and (3) the cells of the stroma. The gradual production of the pigment in this way has been so often described, and is so well known that I need not now dwell upon it. In certain morbid conditions we see this process widely extended, and we find cells containing red blood-corpuscles in the liver, in the lymph-glands, even in the blood itself; and particularly is this the case in those states associated with rapid blood deterioration and destruction, as in acute fevers, when these bodies may be enormously increased. In certain forms of anæmia so abundant are they in the bone marrow and in the spleen that they have been regarded as directly concerned in the widespread hæmophthisis.

The observations of Quincke[1] and his pupils have shown that the liver is the chief seat of blood destruction in pernicious anæmia, but the totally different appearance presented by this organ, even in long-standing cases, to that met with in malaria, shows a radical difference in the nature, possibly in the seat of the hæmolytic action. In the former case, the pigment is chiefly in the liver cells; in the latter, in the stroma and about the blood-vessels. We cannot from this regard pernicious anæmia as an hepatic disorder. The liver, probably, makes the best disposal it can of an abnormally large amount of coloring matter, which is, I should suppose, not brought to it in the same form as in malaria, but rather in a form similar to the raw material of the bile pigment, which would account for the active participation of the liver cells. The deep beefy-red color of the muscles in pernicious anæmia also tells of an abnormally large quantity of coloring matter at the disposal of the tissues.

In chronic emphysema, in mitral obstruction, and in all affections in which the circulation within the lungs is permanently embarrassed, the condition of brown induration which ensues affords a very beautiful illustration of the same process. The blood corpuscles by diapedesis reach the stroma of the air cells, where they are seized upon, just as are coal particles, by the connective-tissue cells, and are gradually converted into a pigment which retains for a long time its brownish tint, but which may ultimately become black.

Neumann, in a recent paper,[2] doubts whether the brown induration of the lungs is really the result of the ingestion of the red blood-corpuscles by the stroma cells. He holds that in many instances, at least, structures within the corpuscles, which resemble so closely the red blood-disks, are in reality only pigment forms having the size and color of the red blood-cells. We certainly see structures within the cells which cannot possibly be mistaken for anything but red blood-corpuscles, and, I think, the expert eye can usually discriminate between such and the round aggregations of pigment, however deceptive may be their form and color.

Phagocytosis has been studied in the process associated with absorption of extravasated blood. Langhans was the first to show that blood effused into the tissue did not simply disintegrate and disappear, but that the connective tissue elements were actively at work, and that no small proportion of the colored corpuscles was ultimately taken into the interior of their protoplasm. This has been amply confirmed, and I think there can be no question as to the fact; but observers are by no means unanimous, however, whether the phagocytes are essen-

[1] Fortschritte der Medicin, Bd. i.

[1] Deutsches Archiv f. klin. Med., Bds. xxv., xxvii., xxxii., xxxiii.

[2] Virchow's Archiv, Bd. 110.

tial in the process. Probably in large extravasations only the peripheral parts are dealt with in this way. The fixed connective-tissue cells with migrated leucocytes all share, I believe, in the process. It must not be forgotten, as Neumann has pointed out, that pigment granules in the interior of the cells may resemble blood corpuscles very closely. However this may be, there can be no doubt that the cells are concerned in the transformation of the hæmoglobin, whether they take it up with the corpuscles or after it is diffused from them.

Remarkable differences exist in the final transformation of the hæmoglobin, resulting in the formation of two pigments, hæmatoidin, which develops chiefly in the central parts of the extravasation, and an albuminate of iron, hæmosiderin (Neumann), which is formed at the boundaries of the clot and wherever the coloring matter comes in contact with the tissues. That this difference is related in some way to the influence of the cells, is in the highest degree probable, though Neumann is not inclined, from his observations, to attribute an important action in this respect to either the fixed or wandering connective tissue elements. The question is one to which a few years ago I gave some study in connection with development of cells containing red blood-corpuscles, and I was much impressed with the truth of Langhans' statement as to the frequency and numbers of these structures in the vicinity of extravasations of all kinds.

In the intestinal canal the leucocytes assist, to some extent at least, in the absorption of fat. Schaefer's observations upon this point[1] show very clearly that during digestion the amœboid cells of the mucous coat become filled with fat globules. How these are obtained we do not as yet know clearly. Whether the fat penetrates between the epithelial cells, or whether the leucocytes pass up between the cells reaching to the surface and here secure the fat, has not been definitely determined; though from the presence of an occasional cell, or even a nest of cells between the cylinders, the latter view is probably the correct one. The leucocytes pass to the central lymph vessels, where they disintegrate, and discharge their load of fat granules which has, meanwhile, in the protoplasm of the cell, been broken up into finer particles, which form the so-called molecular base of the chyle. Possibly, too, the leucocytes may take up other ingredients. It is interesting to note that in many of the lower animals the amœboid cells of the endoderm possess an active digestive function. The observations of Parker and Lankester appear to confirm fully the researches of Metschnikoff on the phenomena of intercellular digestion in invertebrates.

So far, we have been dealing exclusively with the action of phagocytes under normal conditions. And it is clear that these mesodermic cells have important functions throughout the life-history of the organism. Not only in the early steps in the development of the blastoderm do we see them actively at work, but in various stages of development, particularly in that of the bone, their action is of the first importance. In the mature body we have seen that in the lungs, in the intestines, and in the blood-making organs, the phagocytes have most essential functions; but the question of chief interest to-day relates, not so much to this normal process about which there has never been much doubt, as to the supposed part which these cells take in protecting the body against the invasion of parasites.

(To be concluded.)

ACUTE MANIA AND MELANCHOLIA AS SEQUELÆ OF GYNECOLOGICAL OPERATIONS.[1]

BY T. GAILLARD THOMAS, M.D.

THE object of this paper is to place on record what I think must be a rather remarkable experience as to the occurrence of acute mania and melancholia as sequelæ of gynecological operations.

Before proceeding with my subject, I desire to call attention to the fact that I do not announce these peculiar and alarming states as complications, or necessarily as results, of operative procedure, but merely as sequels which may or may not be dependent upon it. Further, in this connection I would disclaim the position that the operations performed for the relief of diseases peculiar to women are especially liable to such sequences; but all the surgery which I do being of this character, I am forced, as I limit myself to my personal experience, to confine myself to this field.

Let me clearly and distinctly define my idea of the conditions entitled acute mania and acute melancholia. The former is a sudden, decided, and violent aberration of the intellect, usually following a preëxisting melancholia of slight character, and marked by mental exaltation, violent and frequent ebullitions of emotional nature, rapid and irregular muscular efforts, and which is usually unattended by a tendency to inflict injury upon the patient herself or her attendants. The eyes are bright and piercing in their glance; the tongue red at the edges and furred at the centre; the pulse rapid, and the temperature somewhat, though, in the early stages of the affection, not much elevated. The patient speaks with a sharp, metallic, unsympathetic voice, pitched high, and talks rapidly and incoherently.

Acute melancholia is a rapidly developed aberration of the intellect, marked by depression of the mind instead of exaltation. The patient is less excited and less turbulent; sadder, quieter, and more depressed in her bearing. She looks gloomy, and often declares that her death will certainly occur very soon. At times she becomes calm; at others she weeps and bemoans the fact that she is pursued by a Nemesis, in consequence of some crime which she has either committed, or of which she is falsely accused.

I shall relate to-night six illustrative cases. Out

[1] Read before the New York Academy of Medicine, April 4, 1889.

of these, four were violent, and showed great mental exaltation throughout; two were melancholic in their development, but they were acutely, violently melancholic, bustled about wringing their hands in their busy distress, and after a short illness they died, as did two of the four who presented symptoms of pure exaltation.

Case I.—Mary M., aged twenty-one, single, by occupation a cook, had, during the year before I saw her, noticed an abdominal enlargement which had steadily and rapidly increased. During this time she had emaciated very rapidly, was at the time that she came under my care extremely weak and low-spirited, and now felt that, unless relieved very soon, she would die from exhaustion. Physical exploration revealed a large accumulation of fluid in the peritoneum, and, in addition, a round tumor occupying the whole of the left side of the abdomen.

Although the case was not looked upon as a favorable one for operation, it was determined that, since extirpation of the tumor offered the only chance for the saving of life, it should be resorted to. Accordingly I undertook the operation. The patient rallied well after it. She was kept upon beef-tea, milk, and gruels, and quieted by the administration of opium. Her pulse kept up to about 100, respiration was normal, and nothing existed to excite alarm, except the extreme nervous depression of the patient. She asserted that she would certainly die, and really seemed convinced that such would be the case. With the exception of this symptom, she appeared to be progressing favorably until the seventh night. Then she seemed more than usually nervous and excitable, and desired to see the priest, who was accordingly sent for.

On visiting her early on the morning of the eighth day, I found that a great change had come over her during the night. Her eyes were wild and haggard, her face maniacal, her tongue red and dry, and she constantly talked in an incoherent and violent manner, as is so often found to be the case in puerperal mania. As I entered the room she covered her face with the bedclothes, and screamed out that I had leagued with the priest to murder her. Nothing would pacify her, or dissuade her from this view. After soothing her for some time, I succeeded in getting near enough to her to find that the pulse was beating at 160 to the minute. She remained in the maniacal state which I have described till evening, when she sank into coma and died. No post-mortem could be obtained.

At the time of this patient's death, now exactly twenty years ago, I regarded the condition which destroyed her life as one of acute septicæmia, a pathological factor which was only then coming into notice, and one of which we knew almost nothing. That I was in error, I am now convinced by long and melancholy familiarity with septicæmia, and my conviction will, I think, be shared by all in this assembly.

This case was by far the most rapid that I have ever met with. Its acute stage could not have lasted more than thirty-six or forty hours. Its prodromic, or melancholic, stage had existed ever since the operation. It was in all probability that mental state which made the patient constantly persist in the asseveration that her death was certain.

An examination of the membranes of the brain would have been most interesting in this case, but the patient's family, who were very ignorant people, would not yield to any solicitations in reference to the matter.

Case II.—Mrs. X., a wealthy and fashionable lady, came under my care on account of very severe suffering at her menstrual periods. She was thirty-five years of age, the mother of four children, and a stout, well-made, and very handsome woman. Her health was perfectly good except in this respect; as her menstrual periods approached—that is, about five or six days before them—she would begin to suffer such intolerable neuralgic pain in the regions of the ovaries that her life was rendered wretched. She was seen with me in consultation by two of the most eminent general practitioners of this city, and sustained by their concurrence, and encouraged by the wishes of her family, I removed the ovaries.

She recovered rapidly, but at the end of three weeks a low grade of melancholia developed, which soon took on the form of violent acute mania, marked by tendency to strike her attendants. So violent did she become that I removed her to one of the best lunatic asylums near this city. Here she remained for four or five months, entirely insane. Then she recovered and returned home, and although six or eight years have now elapsed she is perfectly well; free, of course, from menstrual troubles, and the ornament and stay of a charming family circle. I have seen her within the past month, and no one would suspect that the well-poised and quiet woman of to-day was ever a lunatic in the wards of an asylum for the insane.

Case III.—A Jewess, multipara, aged thirty-five years, entered my service in the Woman's Hospital and was submitted to the operation of perineorrhaphy. There was nothing peculiar in this operation as to severity, or any other feature, and after it she did perfectly well until the ninth day, when the sutures were removed. At that time she became violently maniacal, talking constantly, jumping out of bed, throwing her arms about, and berating her attendants in strong, though not absolutely improper, language. It proved so utterly impossible to control her that a straight jacket had to be applied. The patient raved violently for four days, and then fell into a comatose condition and died.

Case IV.—Mrs. R., a multipara, forty-two years of age, who had for years suffered from retroflexion of the uterus which was marked by profuse menstruation, came to me from Liverpool, England, for the repair of a badly lacerated cervix uteri. The operation was performed at my private hospital, and presented no peculiar features. Five or six days after this Dr. Chambers, my associate in the hospital, told me that the patient's manner struck him

as very peculiar, and asked me to observe it closely. But I could detect nothing until some time after removal of the sutures, which took place on the ninth day. Then she told me that in a few days she wanted to have a private conversation with me about a terrible crime which she had committed some years ago, and the memory of which had ever since produced the greatest remorse in her mind. Two weeks after operation the patient went to the home of some of her friends in this city, rather odd in her manner and inclined to allude to the mysterious circumstance of which I have just made mention, but still sane in the general acceptation of the term.

After remaining away for two weeks, she returned to my hospital, suffering from acute melancholia. She was constantly depressed on account of remorse for a supposed crime; would sit silent for hours; then get up and pace the room slowly and solemnly, wringing her hands, weeping, and bemoaning her sad lot. She continued in this state, gradually growing weaker, for ten days, when she became comatose and died. Uncontrollable insomnia was one of the most marked features of the case.

CASE V.—Mrs. C., a multipara, sixty-five years old, was submitted by me in my private hospital to amputation of the breast. Even before operation she seemed to be a flighty and eccentric person, but after it all her symptoms were intensified. On the ninth day the sutures were removed, and from this date the patient became greatly depressed, was sure that she could not recover, and wept almost constantly. She suffered during the earlier part of her illness from insomnia, and continued to do so until the symptoms of coma began to show themselves. As the state of acute melancholia advanced she would cry bitterly by the hour, refusing to speak, and even to answer questions by nodding the head. She refused all nourishment, and for a time was sustained entirely by rectal alimentation. Feeding by the stomach pump was thought of, but rejected, because in the patient's weak condition the overcoming of the resistance necessary for passing a tube down the œsophagus would have produced a dangerous result. This patient lived for about two weeks after the breaking out of the attack, and then slowly passed into coma, and died. Toward the close of the case the urine became albuminous, and presented hyaline casts, but not earlier.

CASE VI.—Mrs. M., a widow over sixty years of age, who had in early life borne several children, entered my private hospital to have a cancerous breast removed. Even before the operation, her manner struck both Dr. Chambers and myself as being queer, but the thought that she suffered from any real mental aberration was far from our minds. About a week after the operation she began to grow noisy and irritable, and by the ninth day, when the sutures were removed, she was at times, during the night chiefly, absolutely maniacal. Then periods of perfect calm and lucidity of intellect would occur and last for hours.

At the end of three weeks from the time of operation, partly in consequence of her earnest desire, partly because we thought that a change of scene and surrounding would benefit her, she was allowed to return home. Here, in a few days, violent mania developed, and at the time of the present writing the patient is still insane.

What her exact condition now is I cannot say, for I have to rely merely upon non-professional reports.

There is very little literature extant upon this subject, which until very recently has appeared to attract no attention. For obtaining what little there is I am indebted to two of my friends, Dr. Paul F. Mundé and Dr. Andrew J. McCosh, who have kindly looked it up for me. Prior to the year 1887 there is nothing. During that year Dr. Edward J. Ill, of Newark, N. J., published a very interesting little pamphlet, embodying his own experience and that of some of our German colleagues, entitled "Acute Psychoses following Gynecological Operations."

Dr. Ill collected the records of ten cases, in which acute mental aberration followed gynecological operations. Of these, three occurred in his own practice; one, a case of acute mania, and another, a case of melancholia, followed ovariotomy; and the third, a case of melancholia, resulted from the performance of a minor operation upon the bladder. All recovered.

Reports of the seven cases which follow were all drawn forth by the discussion excited by a paper read by Graube before the Berlin Gynecological Society in 1887. One case reported by Graube occurred after perineorrhaphy, performed by Paul Ruge, and is entitled by the reporter a case of hypochondriasis. The second case was reported by Duerelius as following amputation of the cervix. Czempin reported five cases of acute insanity which occurred at Dr. A. Martin's hospital. Of these, two followed excision of the rectum for carcinoma; one an operation for prolapse of the uterus; one an excision of hemorrhoids, and one followed ovariotomy, which ended fatally on the tenth day, the mania being the cause of death.

In the same year Guanck reported a case of severe melancholia following simple perineorrhaphy.

In 1888 Werth, of Kiel, read a paper on this subject before the German Gynecological Society at Halle, in which he stated that in three hundred operations on the female genital tract he had in six instances observed psychical disturbances, due to the operation. In two cases the operation was total extirpation of the uterus; in two removal of the ovaries, and in two ovariotomy. One patient was violently excited before the operation. In five cases the mental disturbance took the form of melancholia and in one of mania. In one case the psychosis appeared five days after the operation; in one eight days after; in one two weeks after; in another three weeks after, and in the two remaining cases it developed after the patients had been discharged. Of

the six cases three recovered; one after fifteen days, one after four months, and one after eight months. In two of the remaining cases there was no improvement, and the third patient committed suicide three months and a half after the operation. The phenomenon could not be referred to iodoform poisoning, as the drug was used sparingly or not at all.

Sänger, in discussing this paper, said that he recalled several cases in which cerebral symptoms had developed after gynecological operations. In two instances these were clearly referable to iodoform, though little was used on the dressings. In spite of the facts stated, however, he believed that patients with pelvic troubles having a tendency to psychoses should be treated in the same manner as other women.

In an article by Fillebrown, of Hamburg, published in the *American Journal of Obstetrics* for January, 1889, the author mentions three cases of mental disturbance following gynecological operations, observed by Prochowick, of that place. In one case there was removal of the uterus; in one, cystocele and perineorrhaphy, with amputation of the cervix; and in the third, ovariotomy. In one case intense melancholia came on in four months after operation, and when the report was made, nearly three years after, although the patient had improved very decidedly, there were still periods when she showed signs of excitement. In the second case melancholia appeared three months after operation, and one year after, at the time of his writing, the patient still had attacks at intervals, though she was improving steadily. In the third case violent mania developed three months after operation, from which the patient entirely recovered.

In four out of my six cases there was evidence of eccentricity even before operation; and in two of these four cases it was quite marked at times. In all my cases except one there were distinct prodromic symptoms following operation and antedating by some days the formal outburst.

In none of my cases could I discover evidences of hereditary tendency to insanity.

Out of my six cases, four died, one completely recovered, and one case is still in progress.

In all my cases except one the renal secretion was carefully watched and examined; and in none did the kidneys appear to be factors in the mental state.

In four out of my six cases not a particle of iodoform was used at any time; so these are out of consideration in reference to iodoform poisoning as a factor. In the two remaining cases iodoform was used, as I always use it, very cautiously and entirely on the line of cutaneous union, where absorption would have been next to impossible.

Should the suspicion enter the mind of anyone that one or more of my violently maniacal cases may have been instances of sudden and severe septicæmia marked by delirium, I can merely point to my very large experience with septicæmia in its various forms, and reply that I feel very confident that the suspicion is unfounded.

It will be seen that, my cases being added to those recorded by others, twenty-six instances of acute mental aberration following upon the performance of gynecological operations are now placed upon record.

Before concluding, permit me to propound to this learned body certain questions which in this connection have suggested themselves to my own mind.

1st. Were these twenty-six cases of mania and melancholia really due to the operations which immediately antedated them, or did they follow as mere coincident states, *post hoc sed non propter hoc?*

2d. Any great mental strain may be followed by mania. Is it at all remarkable that in the vast number of gynecological operations which have been performed during the last quarter of a century in America and Germany, twenty-six cases of this malady should have occurred?

3d. If the mania which followed operative procedures in these twenty-six cases was a consequence of them, how in the future is a tendency to the accident to be avoided?

4th. Are the operations of gynecology any more likely than other surgical procedures to disturb the condition of the mind?

It has been said that an ignorant man may ask in a moment questions which a philosopher cannot answer in an age. In the present connection I willingly assume the former of these positions. May there be those present to-night who feel prepared to assume the latter, and may their efforts belie the aphorism which I have just quoted.

AN IMPROVED FORM OF SUSPENSION IN THE TREATMENT OF ATAXIA, ETC.

By S. WEIR MITCHELL, M.D.,
SENIOR PHYSICIAN TO THE INFIRMARY FOR NERVOUS DISEASES, PHILADELPHIA.

Suspension in various ways has been so much used in the Infirmary for Nervous Diseases that the novel treatment of ataxia by it has created with us little surprise. A large number of patients are at present using this means, and before long I shall report results; they are so far encouraging.

It has seemed to me, however, that suspension by the armpits is but a stupid plan; for most people it is so painful as to cause the real limit to the time of suspension, which otherwise might be experimentally prolonged.

In watching the application of the Russian apparatus, I recalled the ease with which a child may be lifted from the elbows. Out of this thought came the apparatus figured. It has these advantages: It

bruises no nerves; does not arrest the circulation; is painless, and can be borne a long time, if we need to use it long, and so makes it possible to learn the value of more prolonged suspension. It will be seen that a separate pulley and cord govern the amount of pull on the head. The lift is made from the elbows, and then the head is drawn upon as may be required.

The apparatus is simply two leather slings for the elbows; a band confines the arms to the waist. (See illustration.) The relative comfort of this means of suspension is really remarkable.

By the use of this device we have been able to suspend a person over twenty minutes in perfect ease. To distribute the pressure upon the arms and trunk the vertical straps are widened under each elbow to about four or five inches and reinforced with leather. Sweeping round from the front to the back upright is a wide band which comes against the outer aspect of the upper arm, yet leaving the point of the elbow free from contact. From one elbow leather to the other and securely riveted to each, both across the front and back, pass stout straps adjusted each by a buckle. Again, across the upper part of the chest another strap encircling the trunk gives additional support—not very essential, but well for nervous folk who fear they may fall.

The adjustment of the head was a vexatious problem, but we have solved that now to our satisfaction by one of two ways. By the second pulley, described above, or by a simple mechanism thus: To the ring of each cheek-piece is attached a stout cord which passes over a hook dependent from the large metal cross-bar and thence by a strap inserted in a buckle made fast to the rear elbow leather one on each side. These hooks are about fourteen inches apart. With either of these mechanisms we can raise a patient from the ground by his elbows, and then proceed to adjust the amount of pull needed for his head.

LOBULAR EMBOLIC PNEUMONIA.[1]

BY THOMAS E. SATTERTHWAITE, M.D.,
PROFESSOR OF PATHOLOGY AND GENERAL MEDICINE IN THE NEW YORK POST-GRADUATE SCHOOL AND HOSPITAL.

EMBOLIC pneumonia, though recognized and described by Laennec[2] in the early part of this century, was not understood by him. It was then classed as "pulmonary apoplexy." But the earlier experimental researches of Virchow[3] continued by Cohnheim[4] and Litten,[5] and pathologists of even later date have portrayed this subject in a clear and satisfactory manner.

It is proper to state, at this point, that embolism of the lung, as here related to pneumonia, is a matter quite distinct from the so-called pulmonary embolism or its ally cardiac thrombosis. They are associated in our mind with occlusion of the whole pulmonary artery or its larger branches, and the attacks are very acute. Embolic pneumonia is an insidious affection, subacute or chronic in its course; manifesting comparatively few symptoms, and therefore deserving to be classed among the *latent* pneumonias.

In examining a lung that has been the seat of embolic pneumonia, we detect at a glance that it contains one or more nodules of spherical, conical, or pyramidal shape. They have a more or less firm or resistant feel and stand out prominently from the adjacent lung tissue, and vary in color from a dull red to a gray or grayish-yellow; these several tints representing the successive stages of pneumonia, and corresponding in a chronological sense with the stages of engorgement, red and gray hepatization, and resolution or suppuration; such as are characteristic of all true parenchymatous pneumonias. Besides, there is seen roundabout each of these areas a zone of œdema, in which the bloodvessels are more or less filled with stagnating or slowly moving blood, while the alveoli and interstitial tissues are permeated with bloody serum, together with the altered solid constituents of these several parts. Now, though this process may be called lobular, since it is confined to single lobules or groups of them, it differs both from broncho-pneumonia whether in the immature or mature lung, in that the origin of the disease may be traced to the arterial supply, and not

[1] Read at the meeting of the New York State Medical Society, February 6, 1889.

[5] Litten, Untersuch. ueber den haem. infarct., Berlin, 1879; Zeigler.

to the bronchial tubes. And, in fact, embolic pneumonia often exhibits the characteristic hemorrhagic infarction, due primarily to plugging of an arterial branch. For in the human lung infarctions from emboli are produced with comparative ease, as we shall presently see.

Indeed, it may be stated that pulmonary infarction from embolism is the rule, in certain forms of cardio-vascular disease and in pyæmia; while the exceptions can be explained in a simple manner. In other words, clots in the veins or in the heart, or any form of endocardial inflammation, and pyæmia, tend directly to embolism of the smaller pulmonary arteries, and hence to infarction and pneumonia; for pneumonia is the natural and regular sequence of pulmonary infarction (from the lodgement of an embolus), even though clinical signs do not betray the inflammation to us.

Since then, such pneumonias are both lobular and embolic it is eminently proper that their characteristics should appear in the nomenclature of pneumonia, and the term *lobular embolic pneumonia* has a claim to recognition.

And further, it may be said of embolic pneumonia, as of broncho-pneumonia, that it can never become lobar unless by a union of the areas of lobular consolidation. I have never seen such an occurrence and am inclined to question whether it ever has been seen. The nearest approach to lobar implication I ever saw was in a case of so-called malignant endocarditis where a portion of the right middle lobe was the seat of an abscess 3 × 1½ inches in diameter. Suppuration in this case was, of course, a sequel to the pneumonia, rather than an integral part of the disease proper.

Now though it is proper to admit here, that the pneumonia called embolic can exist without the presence of an embolus that can be demonstrated at a post-mortem examination, and, on the other hand, that embolism can occur without infarction, still I am prepared to maintain that embolism is competent to produce (as I have already said), each and every example of the disease here designated.

To demonstrate the views of those who recognize embolic pneumonia as a separate form of lung inflammation, it will be necessary to refer to certain antecedent pathological conditions governing embolism. The first to be considered is *thrombosis*, which may be briefly described as the clotting of blood anywhere within the blood-vascular system, whether in veins, arteries, capillaries, or in the heart itself. On the other hand, *embolism* means the plugging of a vessel anywhere, by means of a solid body driven into it. Embolism occurs within the arterial or portal systems, where the current flows with such rapidity that it can force a solid body into a branch or twig and hold it there impacted. The obstructing body is the *embolus* or *plug*. In thrombosis the clot is called a *thrombus*. But a clot or thrombus may be carried to the heart by the venous current and then enter the arterial. The moment it lodges, so as to plug the vessel, it becomes an embolus. Hence, thrombi originating within the domain of the portal system will become emboli so soon as they have been carried by the portal blood to the viscera it supplies, and have effected a lodgement. But a further consideration of this subject is apart from the matter in hand.

We first need to know the causes of blood-coagulation (thrombosis), and without going into wearisome physiological details it is sufficient, for the purposes of this paper, that we recognize its chief determining causes. In so doing we must accept the dicta of physiologists, who tell us that it is chiefly due to the contact of white corpuscles with abnormal vascular tissue. This explanation is suited best to explain coagulation in the moving currents of blood; and has been definitely established by microscopic research.

But coagulation will also occur in any vessel, whether sound or unsound, if only the blood current be arrested. In this latter instance the red thrombus is formed, and from the blood as a whole; in the former instance, the white or mixed thrombus is developed, the one being constituted almost wholly of white blood-corpuscles; the latter from the white with an occasional (often accidental) admixture of the red. These last-mentioned thrombi, the white and the mixed, are slowly but regularly converted into fibrinoid masses, by the alteration of their protoplasmic contents.

Hence, it is apparent that thrombi are chiefly due to alteration in the walls of vessels, or to stagnation of their contents; but as the blood is seldom at rest, and then only for a very brief period, and in comparatively few morbid conditions, while injury or disease of vessels is a matter that is liable to occur frequently during the life of any individual, it follows that the white or mixed thrombi are the most common sorts of thrombi that are to be met with. When red thrombi are formed, it is chiefly in the larger veins, generally of the lower extremities; or in the chambers of the heart.

In the first instance, they find a favorite place for formation behind the valves of the veins, and growing by successive accessions of solid matter from the blood, they extend upward until another valve is reached, where they remain until the vessel is dilated to its utmost capacity, and again extend upward to still another valve. In this way the veins become "corded," the nodular expansions (that can be felt through the skin) indicating the situations of the valves.

Or red thrombi may occur within the heart cavities, whether ventricular or auricular. Their formation presupposes a dilated heart. Now it is the right heart

that is most subject to this affection, caused chiefly, in my experience, by mitral disease. Owing to its weakened action, clots form in and about the columnæ carneæ, or in the crypts of the dilated right auricle. But thrombi may also be formed in any cavity of the heart. Often they form about or on points of endocardial disease, and so at the cardiac valves, or on ulcerated chordæ tendineæ.

These two factors of coagulation may, however, be associated, as after parturition, where clots in the uterine sinuses may be due both to an enfeebled circulation and to the mechanical laceration of veins following the detachment of the placenta.

The separation of clots in such cases may be extensive, and the thrombi may gradually work their way to the heart, probably obtaining accessions as they proceed; and then passing through the heart, lodge in the main trunk of the pulmonary artery, or in one of its important branches. These accidents (as they may be called) are of an acute and very dangerous character, causing sudden death; or, at any rate, symptoms of violent angina. But a consideration of them does not form a part of the purpose of this paper. We have to do merely, as I have already said, with such smaller thrombi as occlude arteries of moderate calibre, leading to subacute or chronic pneumonias.

Again, it not infrequently happens that a morbid growth impinges on the lumen of a vein or artery, and either the progress of the disease or some mechanical injury causes the separation of a fragment that thus enters the venous current and is carried to the right side of the heart. In a case of carcinoma of the rectum that came under my observation in hospital experience, I think it not unlikely that a portion of the diseased mass was dislodged by the operation of mechanically divulsing the strictured part.[1] Pulmonary embolism with pneumonia followed, due very probably to the entrance of a carcinomatous nodule into the upward blood-stream.

It is not so easy to understand how embolic pneumonia may be produced by solid particles carried from the left heart or arch of the aorta. But there is no reason to suppose that the disease *may not* so originate, though the chances of lung implication are comparatively small; because the possible area for the origin of the disease is so limited, and because the solid particles must be comparatively minute. For in this case the bronchial arteries have to carry the disease.

They, however, are distributed to the septa of the lung, and, so far as we know, are not terminal arteries; but it is manifest that embolism can occur in them as well as in branches of the pulmonary artery, though there is no reason that it should be followed by a hemorrhagic infarction.

[1] This case is not included in my Table of 18 cases.

With this brief setting forth of thrombosis and its supposed causes, in the light of modern physiological research, we are prepared to consider embolism in its most important particulars and sequences.

I may premise, by saying that embolism is often, or usually, a trivial matter; that is, in so far as relates to the system at large, because in most organs of the body a collateral circulation is soon and satisfactorily established; the only damage resulting being that the lumen of the vessel between the lodgement of the embolus and the next distal branch is obliterated; provided, of course, the plugging be complete and the plug suffer no disintegration.

But embolism takes on a different aspect so soon as it occurs in an organ provided only or chiefly with *terminal vessels*. Now, as these are the main source of supply in the brain, lungs, and kidneys, it is there that we find typical examples of embolism with infarction. In accepting the conclusions of Cohnheim and Litten on the production of an infarction, the subject is rendered intelligible.

Cohnheim was the first to clear away the main difficulties to an understanding of the process. He did it by experiments on the tongue of a frog. Plugging a nutrient branch, he observed that anæmia of the district supplied was the first important result; but it was soon followed by a backward motion of the venous current, which not only filled the veins but also the capillaries and arterial twigs, behind the plug; the result being *primarily* that wedge-shaped or pyramidal portions of lung tissue were developed, having a dull red color and soft consistency. This was the true hemorrhagic infarction. Reasoning from analogy, it was therefore presumed that a pulmonary infarction was produced in a similar manner.

The explanation offered was that when the pressure was taken off from the plugged pulmonary branch, (the venous pressure remaining constant), a motion of the venous blood took place in the direction of least resistance; which was backward toward the capillaries and thence into the empty arterial twigs. This explanation left out of consideration the arterial pressure in the bronchial arteries, which, though comparatively slight, Litten appears to have found was of decided consequence—and, indeed, was necessary. Hence, we may conclude that the first stage of an infarction is dependent not only upon venous pressure, but to some extent on arterial. But we have to go a step further. Not only are the vessels in the infarct distended with blood, but there is a transudation from them of their liquid contents, and a diapedesis of corpuscles, with naturally some proliferation of the normal solid elements of the part, as the result of vascular engorgement. Thus an infarction is produced, and now we stand on the threshold of a pneumonic inflammation.

For the fact that these infarctions are soon sur-

rounded by a zone of inflammatory œdema, and that the consolidated areas undergo all the successive changes of alveolar inflammation, *shows* that we are in the presence of an inflammatory process—in other words, a true pneumonia; even if the clinical phenomena are often obscure, and even appear to be absent. These remarks are apposite in their place, because it is not every clinician who is willing to recognize the embolic process as the source of true pneumonia.

Embolism does not, however, always produce a hemorrhagic infarction, and, so far as I know, the reason has been sought in the following facts: 1. That the bronchial arteries liberally supply the septa about an embolus; or, 2. That pulmonary capillaries are unusually capacious. Admitting, however, the truth of these allegations, about which there seems to be no doubt, it appears to me that they are merely *in the direction* of the truth; for two important conditions of the adult lung have never, I think, thus far been considered, both of which would operate toward preventing infarction. These are: 1. The retention by the lung of its fœtal state; and, 2. The effects of antecedent inflammatory conditions.

If any one will take the trouble to examine a number of lungs, he will find that there is much difference between these as to the completeness of their development. In some lungs the lobules, especially of the periphery, are so distinct that they can easily be pulled out and separated from each other like the leaves of a tree. In other cases they are more or less completely amalgamated together, so that they can be parted with difficulty; or the amount of fibrous tissue may be so great as to remind one of the immature lung as it is seen prior to the fifth year of life. Again, from a variety of reasons, there may be some interstitial thickening of the lung, as in phthisis, but it is particularly noticeable in the chronic interstitial pneumonia of heart disease. Consequently, in cardiac disease, we may have two processes going on hand in hand: 1. An interstitial thickening, due to chronic venous congestion; 2. Embolism.

Now, in all these conditions, whether congenital or acquired, where the lung is provided with an unusual amount of fibrous tissue, we have increased vascularity, and hence a collateral circulation is easily produced. And, therefore, embolism in cardiac disease does not necessarily tend to hemorrhagic infarction, because nature has guarded against it in several ways. In fact, in any lung, circumstances *must* favor to admit of its development. Near the root of the bronchial tree it seldom—perhaps never—forms, because the capillary circulation is too active. But let an embolus get lodged near the edge of a lobe or in some prolongations of lung tissue (such as we often see, owing to the abnormalities of the lung, especially of the right); then the conditions are favorable to an infarction, and, as a matter of fact, there we find it in all its completeness.

Hence we see that pulmonary infarction is not easily produced in the normal adult lung, and even in a crippled lung, if the cardiac and respiratory movements are healthful, the danger is comparatively slight, because these capillaries are active, and they often and generally can prevent it.

Now, just as capillaries will tend to prevent an infarction, so they will diminish its area after it has been developed, and the original size and shape of the obstructed area will be modified largely, in proportion to their activity. Consequently, an infarction tends to diminish in size, and may, in part at least, be removed while it is going through the successive stages of pneumonia. This statement is sustained by the fact that an infarction is always smaller than the area of the nutrient supply—*i. e.*, in an uncomplicated case, as in the later stages of nonvirulent infarctions. This pathological fact bears upon the prognosis.

But we have not considered the topic of infective emboli, a subject that has only recently been cleared up, to the extent of our understanding its main features. Infective embolism may be due to thrombi, bits of diseased tissue, or bacterial organisms. A study of these processes leads us to a consideration of the so-called malignant endocarditis and pyæmia. Let us review some of their main characteristics. Suppose, for example, that a thrombus has formed at some focus of infection. Disintegration of the clot or dissolution of some morbid product takes place, and the scattered fragments are carried upward to the right side of the heart, and so on to the lungs. In their progress they may be arrested at some point, possibly at a valve in the veins; perhaps at a rough spot in the vessels; perhaps in some nook or cranny of the right heart. A secondary thrombosis is now set up; if in a vein, occlusion of the vessel may occur. Then phlebitis follows, and it is of a suppurative character.

From this new point of departure the infective matter is prepared to start forward with enlarged proportions. Supposing that some of the débris is detained upon a roughened valve, further augmentation takes place, and a truly malignant endocarditis may ensue. But even the smallest amount of débris, starting from a diseased centre, if only it contains active bacterial organisms, can originate pneumonia by their lodgement in the termination of an arterial twig. And the multiplication of these bodies is so rapid that they will soon form veritable colonies, capable of occluding vessels of considerable size. Supposing, however, that they do not find lodgement until the lung capillaries are reached, we shall still have a pneumonia set up, and just as if

there had been an infection; and it can be called embolic, since the vessel is plugged, though it be only a capillary. Hence, an infarction is not positively essential to the production of embolic pneumonia.

It is not necessary to suppose that in such cases there is a microörganism of definite size and shape; any microörganisms may act in this way. Indeed, it is possible that they act simply as carriers of the poison, while at the same time they are constantly generating it. If they lodge in the capillaries, rupture may readily occur and hemorrhage; and we may call the process pulmonary apoplexy, but the term is misleading. For an understanding of these processes we have to depend upon a substratum of facts derived from animal experimentation, a study of the human lung in its course of development, the teachings of morbid anatomy, general pathology, and processes of reasoning based upon all. In no other way can the matter of embolism be made intelligible.

(To be concluded.)

REPORT OF A CASE IN WHICH A LARGE-HEADED BRASS SHAWL-PIN REMAINED IN THE TRACHEA FOR TEN DAYS, AND WAS REMOVED SEVEN HOURS AFTER TRACHEOTOMY.

Profuse Hemorrhage from the Trachea and Expulsion of a Large Number of Fibrinous Casts.[1]

BY H. R. WHARTON, M.D.,

SURGEON TO THE CHILDREN'S HOSPITAL; ASSISTANT SURGEON TO THE UNIVERSITY HOSPITAL; INSTRUCTOR IN CLINICAL SURGERY, UNIVERSITY OF PENNSYLVANIA.

ANNIE R., aged four years, was admitted to the Children's Hospital January 5, 1889, with symptoms of dyspnœa, which were supposed to be due to the presence of a foreign body in the larynx or trachea, her friends stating that ten days previously she had been playing with a large-headed brass shawl-pin, which she acknowledged that she had swallowed. She had also been under the care of her family physician, Dr. Longenecker, and Dr. T. A. Downs; the latter stated that he had seen the pin in the larynx.

Examination of the patient at the time of her admission to the hospital showed that she presented symptoms of dyspnœa, but not of an urgent character. Auscultation of the lungs revealed the presence of moist râles over their posterior surfaces, most upon the right side, and the patient also had marked paroxysmal cough.

As the case was admitted late in the evening, and as the dyspnœa was not urgent, and the patient was in the hospital under careful observation, Prof. Ashhurst decided to postpone any attempt to search for or remove the foreign body until the following day. Accordingly, on the following day, after an unsuccessful attempt to make a laryngoscopic examination, it was deemed best to perform tracheotomy and to attempt to remove the foreign body. Prof. Ashhurst, under whose care the patient was, exposed the trachea below the isthmus of the thyroid gland and opened it at this point. When the trachea was opened there was profuse bleeding, large quantities of blood escaping from the tracheal wound. A tracheal dilator was hurriedly introduced and the trachea was rapidly cleaned of blood with sponges and feathers, and it was with the greatest difficulty that the trachea could be kept sufficiently free from blood to permit of the child getting a sufficient quantity of air.

It was also observed at this time that there were expelled from the trachea with the blood shreds and masses of fibrinous material, closely resembling those seen in cases of diphtheritic croup in which the trachea has been opened. The amount of this fibrinous material which was expelled and removed with forceps and a feather was so large that we were almost inclined to think that the dyspnœa from which the child had suffered was due to its presence, and that the foreign body had possibly not entered the air-passages. As the hemorrhage had ceased, the dilator was removed and a tracheotomy tube was inserted, and as the child was suffering markedly from the loss of blood, and was breathing comfortably through the tracheotomy tube, it was deemed best to postpone any further attempts to search for and remove the foreign body until she had thoroughly reacted.

The patient was put in her bed and was given carbonate of ammonium freely. Care was also taken to see that the tube was kept free from blood and shreds of membrane, and when I saw her a few hours later I found she had reacted fairly well and was breathing comfortably. Seven hours after the trachea had been opened she began to cough and eject blood from the tracheotomy tube, and I was summoned to see her, in the absence of Prof. Ashhurst.

When I saw her I found she had lost a considerable quantity of blood, and was suffering markedly from dyspnœa. Her color was bad, and she was getting very little air through the tracheotomy tube. I placed her upon the operating-table in a good light and removed the tracheotomy tube and introduced Golding-Bird's tracheal dilator, and upon cleansing the trachea of blood I discovered a large fibrinous cast (see Fig. 1) in the trachea just below

FIG. 1.

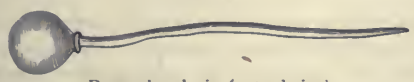
Fibrinous cast from trachea (actual size).

[1] Read before the Philadelphia County Medical Society, February 20, 1889.

the lower border of the tracheal wound, which I removed with forceps. This evidently had occluded the lower orifice of the tracheotomy tube and had been the cause of her dyspnœa, for upon its removal her breathing became good and her color improved.

I took the opportunity at this time to explore the larynx, both from the wound and from the mouth, for the presence of the foreign body, but with a negative result. I now introduced the tracheal tube and she breathed comfortably until after taking something to drink she was attacked by a severe cough, and she soon presented very urgent symptoms of dyspnœa. I again removed the tracheotomy tube and introduced the dilator, and after hurriedly cleansing the trachea of blood and membrane I saw lying close to the posterior wall of the trachea the point of the pin; this I seized with forceps, and with some little difficulty removed it. This proved to be a brass shawl-pin, about two inches in length, with a large head (see Fig. 2); and from its length and the position

Fig. 2.



Brass shawl-pin (actual size).

which it occupied in the trachea, I think its head must have been impacted in the right bronchus. After removing the foreign body the tracheal tube was again introduced, and as her breathing was quiet and regular she was placed in her bed, and soon fell into a sound sleep.

In this case I thought it advisable to introduce the tracheotomy tube after removal of the foreign body, as it had by its presence set up so much tracheal irritation, as evidenced by the membrane and hemorrhage, although I think in uncomplicated cases it is better not to introduce any tube if the foreign body has remained only a short time in the trachea.

The child for the next few days continued to expel from the tube some bloodstained mucus and small particles of the fibrinous matter before referred to, and at the end of six days the character of the expectoration from the tube had changed and consisted simply of glairy tracheal mucus. The tracheotomy tube was now removed and the wound allowed to heal by granulation, and the child was discharged from the hospital with the wound healed on January 21st.

The above case presents some points of clinical interest which I myself have never seen in cases of foreign body in the air-passages, and which I am not aware have been pointed out by other observers.

I refer to the profuse hemorrhage which occurred from the trachea after it had been opened, and to the presence of the large quantity of fibrinous material which was expelled from the wound at the time of operation, and which was removed subsequently. The source of the hemorrhage is, in my mind, uncertain, either arising from the congested and inflamed mucous membrane of the trachea, as the result of the separation of the fibrinous casts or from injury to the mucous membrane by the foreign body, and I am rather inclined to attribute its source to the former cause.

The fibrinous casts which were expelled and removed from the trachea, which so closely resembled the membrane which is seen in cases of croup, is a feature of special interest, for in a number of foreign body cases which I have seen, and in which the trachea was opened after the offending body had remained in it for some time, I have never seen a similar condition obtain. Although in one of these cases, in which a foreign body, a portion of a grain of Indian corn, had been in the trachea for two weeks, there was such marked swelling of the mucous membrane of the trachea that its calibre was almost occluded. In this case the casts seemed to be due to the deposit of lymph from the irritation produced by the presence of the foreign body.

The prognosis in cases of foreign bodies lodged in the air-passages is always grave, for although there are many recorded cases in which such bodies have occupied this situation for months, or even years, without causing alarming symptoms, and recovery has taken place upon their expulsion or removal by operative means.

On the other hand, there must be taken into consideration the danger which constantly threatens the life of the patient from the foreign body changing its position, and suddenly occluding the chink of the glottis, or of the body increasing in size, if its composition be of such a nature as to admit of this from the absorption of moisture from the secretions of the respiratory passages, rendering its expulsion through the glottis less likely.

We must also take into consideration the inflammatory changes which the presence of a foreign body in the larynx, trachea, or bronchus may set up if it has occupied either of these positions for any considerable time, and which of themselves have led to a fatal issue after its expulsion or removal.

The treatment of cases of foreign bodies in the air passages depends somewhat upon the position which they occupy, upon the individual peculiarities of the case, and upon the urgency of the symptoms arising from their presence.

When the foreign body occupies the larynx, if the dyspnœa is not extremely urgent, it may be located by a laryngoscopic examination and its removal by laryngeal forceps is a safe and efficient procedure in skilful hands, but I think in the vast majority of cases this procedure will not be satisfactorily accomplished, for the reason that most patients, especially children, require a certain amount of training before the ordinary laryngoscopic manipulations can be made with satisfaction.

The employment of emetics in the treatment of foreign bodies in the air-passages, while not entirely free from danger, has proved of little service in effecting their removal.

Inversion of the body as a method of treatment of cases of foreign bodies in the air-passages is now generally regarded as a dangerous procedure from the risk of the body becoming impacted in the chink of the glottis, unless there has previously been made an opening into the trachea, or unless the surgeon is prepared to perform an immediate tracheotomy if dangerous symptoms arise.

When the foreign body has passed through the larynx and entered the trachea or bronchus, I think the chances of its spontaneous expulsion are very much diminished; and I think then, a laryngotomy, from the ease and rapidity of its performance, if the dyspnœa is very urgent, will be the best operation to select. On the other hand, if the danger is not so imminent, I think a tracheotomy, and preferably one below the isthmus of the thyroid gland, will be found to be the most satisfactory operation to employ, as by this procedure, if care is taken to make the tracheal wound sufficiently large, thus favoring the expulsion of the foreign body, if it be movable; or, on the other hand, allowing the surgeon through it to make a satisfactory exploration of the trachea and bronchi below or of the trachea and larynx above. A tracheal dilator should then be introduced, and the self-retaining dilator of Golding-Bird will be found to be a most useful instrument; or blunt hooks may be used to hold the edges of the wound apart, and when the position of the foreign body has been ascertained it can generally be easily removed with forceps.

MEDICAL PROGRESS.

Phenacetin in the Treatment of Whooping-cough.—DR. R. HEIMANN, of Landau, preports in the *Münch. med. Wochenschrift* of March 19, 1889, some of the successes which he has obtained with phenacetin in the treatment of whooping-cough. Failing to obtain any satisfactory action from antipyrin, he resorted to phenacetin, the action of which proved to be most satisfactory. The paroxysms of coughing which, before its administration were as many as from ten to fifteen, were, after the drug had been taken, reduced to three, and after several days they disappeared altogether, returning only at night, the drug being then withheld.

To a three-year-old boy the author administered 6 grains in four doses of 1½ grains each, to a two-year-old girl 4½ grains in three doses, and to a nursling 3 grains in four doses of ¾ grain each; after-effects were never observed, 1½ grains of the drug sufficing to keep the paroxysms in check for three hours.

To assure himself of the efficacy of this drug, the author omitted its administration in some cases for a day, which resulted in a return of the number and severity of the paroxysms.

Creasote in Lung Affections of Children.—With a few exceptions almost all observers speak well of the value of creasote in tuberculosis, and agree in saying that even if recovery is not to be hoped for, marked improvement of the chief symptoms follows its employment. All the communications hitherto published relate to adults, and PROF. SOLTMANN, of Breslau, is the first to record his experience of the remedy in children. We have, he says, given creasote in chronic lung diseases with little or advanced destruction without considering the presence or absence of bacilli. After all due allowance is made for care in hospital, suitable nourishment, baths, good air, etc., considerable advantage is evidently derived from the administration of creasote, since cases which were not doing well began to improve unmistakably under increasing doses of creasote. He gives two to seven drops of creasote a day—*i. e.*, from one to six grains, while adults were ordered from four to eight, or even twelve grains daily by Sommerbrodt.

Soltmann's prescription is this:

R.—Creasote	guttæ 4–14.
Sp. æther.	vj–xij.
Aq. dest.	℥j ℥vj.
Sacch. alb.	℥iiss.

A teaspoonful every two hours.

It merits especial mention that the creasote was well borne by all the children. Stomach-ache, nausea, vomiting, diarrhœa, inconveniences which often render treatment by creasote impossible in adults, never occurred. Even in high fever, which by all authors is spoken of as a contraindication, the creasote was taken without disadvantage. That the large doses helped to give the good results is probable from Guttmann's experiments on the antiseptic power of creasote on many microörganisms. Very remarkable in many cases was the increase of appetite and gain in body-weight, the diminution of cough and expectoration, and the gradual disappearance of pathological lung-symptoms. He concludes that creasote exerts in chronic lung-disease with suspicion of tuberculosis a markedly favorable influence, especially in cases where there is not much destruction of lung or other severe complication, and where there is not too high fever, the general strength being relatively good.—*London Medical Recorder*, March 20, 1889.

Antipyrin in the Treatment of Whooping-cough.—DR. DUBOUSQUET-LABORDERIE, at a meeting of the Society of Therapeutics of Paris, held February 27, 1889, stated that for the last two years he had used antipyrin in the treatment of whooping-cough. His object at first in using this drug was to overcome the nervous symptoms, but he was soon convinced that it also influenced the catarrh as well as the specific cause of the disease. In 94 cases he obtained improvement in 71; the duration and the intensity of the disease, as well as the number of paroxysms of coughing, were diminished. Unfavorable symptoms were never observed; in no case did the drug affect the urinary function; in two patients he observed a passing cutaneous eruption; only rarely did gastric symptoms oblige the suspension of the treatment, and when they did occur, the impurity of the drug was found to be the cause. For children between the ages of one and three years, the dose administered was from five to fifteen grains, and above that age, from thirty to sixty grains. Dissolved in Vichy or some other mineral water and some syrup added, the drug is easily taken by little patients.—*Gazette Hebdomadaire*, March 15, 1889.

Paracentesis Pericardii.—In the course of an article upon pericarditis (*L'Union Méd.*, No. 31), M. Paul Chéron cites Fevrier's conclusions respecting the indications for surgical interference, and the best method of puncturing the pericardial sac. Such interference, he says, is called for when the effusion by its quantity threatens to arrest the action of the heart; that in such a case the presence of a concomitant pleural effusion must not be overlooked, and, if existing, should be dealt with first. A second ground for intervention is when the effusion is of long standing, and consequently liable to induce change in the cardiac muscles. A third indication is the fact of the effusion being purulent. Fevrier does not refrain from recommending tapping in tubercular pericarditis, in spite of the fact that out of twenty-two cases of this form of pericarditis so treated twenty patients died at various intervals (from eight hours to seven months) after the operation.

Fairly good results have been obtained in hemorrhagic cases, five out of nine having recovered after tapping. In serous effusions simple puncture suffices, but in purulent cases the pericardium must be incised. Out of fifteen cases of purulent pericarditis treated by incision, eleven died. He warns against delaying the operation too long, and attributes to that circumstance an instance where sudden death followed washing out of the sac, the heart being probably degenerate. The site selected for puncture by the aspirator should be the fourth or fifth interspace to the left of the sternum.

For free incision it is recommended to select the fifth interspace, and to incise the tissues layer by layer for a distance of three or four centimetres, taking care to avoid the internal mammary artery, which may need to be drawn inward; then, having exposed the pericardium, it may be carefully incised with a guarded bistoury, the portion of the membrane being drawn forward by forceps. Great care should be exercised in irrigation, if this be employed.—*Lancet*, March 23, 1889.

Sulphonal in Night-sweats.—Dr. Böttnich, of Hagen, reports in the *Therap. Monatshefte* for March, 1889, the following remarkable action of sulphonal. He administered to a lady, eighty years of age, who had passed many sleepless nights, fifteen grains of sulphonal as a hypnotic. The lady suffered so profusely from night-sweats that she was frequently compelled to change her night-dress twice during one night. After the administration of the first dose of sulphonal, she asked the author whether he had given her anything to prevent the sweating, so rapid was the effect.

Further investigations proved that in most cases night-sweats could be overcome by taking thirty grains of sulphonal before retiring. The author compares the action of sulphonal to that of atropin, the former, though, possessing none of the unpleasant after-effects of the latter. Although the remedy was omitted every second night, the sweating in most cases was still quite perceptibly diminished.

Hypodermatic Injections of Quinine in Malaria.—Dr. J. A. Correa de Carvalho, of Extremoz (Portugal), has recently recorded (*Coimbra Medica*, February 1, 1889) a case of malaria which he succeeded in curing by hypodermatic injections of quinine. The patient was a woman aged thirty-five, in whom the disease had reached the cachectic stage. The skin and mucous membranes were discolored, and the spleen, which was very tender on pressure, reached down to the left iliac fossa, and extended toward the right to within one to one and a half inches of the middle line. The stomach was dilated, and the patient suffered much from dyspepsia. The temperature varied from 102.2° F. in the morning to 100.4° in the evening. Sulphate of quinine was given internally in capsules and in pills, but only with the effect of aggravating the gastric disorder. On November 18th hypodermatic injections of neutral hydrochlorate of quinine were commenced, at first in doses of six grains and afterward eight grains. The temperature soon began to fall even in the morning, and by the middle of December it was normal, never exceeding 98.6° in the evening, and being sometimes below 98° in the morning. On January 13th the patient was discharged cured, the spleen being much reduced in size and not at all tender, and the discoloration of the skin and mucous membranes having almost entirely disappeared. Her dyspepsia had also ceased to trouble her. The injections, which were all made under the skin of the forearm, caused a little irritation. A few small abscesses formed around some of the points of puncture, and had to be opened, but gave no further trouble.

The following is the formula of the solution used for injection:

℞.—Basic hydrochlorate of quinine .	gr. xv.
Pure hydrochloric acid . .	♏j.
Distilled water	℥ss.

These ingredients should be placed in a test-tube and exposed to the action of gentle heat. A clear solution will be obtained, each sixteen minims of which will contain eight grains of neutral hydrochlorate of quinine. The solution should be injected warm. Dr. A. Rocha (*Coimbra Medica*, November 15 and 16, 1888) first recommended this method, which he had employed successfully in a patient suffering from malaria, to whom it was found impossible to give quinine in any other way. Drs. Buermann and Villejean had independently described a somewhat similar method a short time before. —*British Medical Journal*, March 16, 1889.

Treatment of Variola and Varioloid with Cocaine.—Dr. E. Ory gives, in an exhaustive article in the *Revue gén. de Clin. et de Thér.*, No. 9, his results obtained with cocaine in the treatment of variola and varioloid. They are as follows: In an extremely severe case of confluent varioloid immediate improvement and arrest of evolution of the papules were observed after the patient had taken somewhat over ten pastilles containing each $\frac{1}{32}$ of a grain of cocaine. Further treatment consisted in the administration of ten drops of a five per cent. muriate of cocaine solution, which dose was repeated four times daily; in less than ten days the patient was cured. In a second case of varioloid a cure was effected by the same method of treatment five days after the eruption first made its appearance. A third case of severe hemorrhagic varioloid healed without scars after five days' treatment. Also, in two cases occurring in children, a cure was effected after five and six days respectively. As already stated, the author administers to adults ten drops of a five per cent. solution four times daily, while

to children were given, four times daily, eight drops of a one per cent. solution. It is often difficult to make a positive distinction between cases of variola and varioloid, as the pustules dry up immediately after the application of the cocaine. The fact that cocaine is capable of neutralizing the variola-virus in the infected body has led the author to believe that it can prevent infection of the healthy organism, and that it should be used as a preventive remedy in the immediate surroundings of the sick chamber.—*Wiener med. Presse*, March 17, 1889.

Antiseptic and Analgesic Cotton for the Dressing of Wounds.—DR. ELLER (*Revue gén. de Clin. et de Thérap.*, March 7, 1889) recommends the following as an analgesic and antiseptic mixture:

R.—Cocaine hydrochlorate	3	parts.
Water	60	"
Boric acid	6	"
Glycerine	8	"
Carbolic acid	2	" —M.

Dissolve the cocaine in the water, and the boric acid in the glycerine; then mix these together and add the carbolic acid.

This preparation serves to render antiseptic as many ounces of cotton as ounces of water have been used. The cotton thus obtained serves as a dressing for burns.

What Medicines may be Given to Nursing Mothers.—FEHLING has opened an important field of inquiry, by a series of experiments to determine what drugs may be safely given to nursing mothers. He found that salicylate of sodium was dangerous to the infant when given to the nurse in doses as large as forty-five grains daily. Iodide of potassium may be given in doses of three grains daily. Iodoform enters the system of the infant more readily through the nurse than when given to the child. Even when the wounds of the mother were dressed with iodoform, iodine was found in the child's urine. He found that mercurial salts given to the mother affect the child very slightly, if at all, and that twenty-five drops of tincture of opium (German Pharmac.) and one-tenth to three-tenths of a grain of morphia could be safely given to the mother. Chloral may be given in doses of twenty-three grains to forty-five grains. Atropine affects the child very quickly, even in small doses. He denies that salads and acids have an injurious effect on the child.—*Medical Press*, March 20, 1889.

Eczema of the Nails.—DR. DE LA HARPE, *privat-docent* in the University of Geneva, mentions in the *Revue Médicale de la Suisse Romande* a somewhat rare case of eczema of the nails, which came under his notice while he was acting as medical officer at the well-known baths of Louèche, or Leuk. The patient was a man of sixty, who had been sent to Louèche by Prof. Hardy. There was no history of gout or other hereditary disease, and up to two years previously the nails had been in excellent condition. The first sign of anything wrong that was noticed was a slight redness about the ungual furrow of the ring finger of the right hand, which was at first supposed to be panaris, but instead of going on to suppuration it was followed by morbid changes in the nail itself, which soon became thickened and friable, with a roughened surface. The nails of the other fingers on both hands subsequently became affected, as shown in figures appended to the paper. When seen by Dr. de la Harpe, the affected nails were swollen, bent transversely, and marked with longitudinal striæ or grooves. Two apparently healthy nails showed fine depressed points.

Regarding the cause of these appearances, which are the first signs of the commencement of the affection in otherwise normal nails, Dr. de la Harpe remarks that he has seen a case of chronic eczema of the hand in which there were a number of longitudinal grooves on the nails, some of them interrupted—that is to say, in sections. The punctate marks on the nails in the case in question may possibly be analogous to the interruptions noticed in this latter case. As to the treatment by means of the Louèche waters, it appears to have effected marked improvement.—*Lancet*, March 23, 1889.

A Cause of Biliary Calculi in Women.—MARCHAND finds women's stays a frequent cause of the formation of gall-stones. The pressure exerted by these articles of dress on the liver is transferred to the gall-bladder and its ducts. This pressure is not uniform; it is more constant by day, but decreases at night, or is exerted only when the form of the thorax is already altered by pressure. This pressure causes the retention of the bile in the gall-bladder. During the daytime the bladder tends to empty itself; in the intervals of digestion, and during the night, there is a tendency to refill itself. If the daily evacuation of this organ is prevented, or only imperfectly effected, there is a recurrence of stagnation of bile and consequent disposition to the formation of gall-stones.—*Medical Press*, March 20, 1889.

A Simplified Method of the Cold Water Treatment of Fever.—DR. PLACZEK (*Virch. Arch.*, CXV) has of late taken up this treatment, at first advocated by Preyer and Flasher, in 1884, and by Hiller in 1886, the latter having successfully used it in treating soldiers suffering from sunstroke. This treatment consists in spraying the entire body surface with water until a fall of temperature is obtained.

In an animal with high temperature, Dr. Placzek succeeded in reducing the same two degrees by spraying the body with one and a half pints of water of from 53° to 59° F. and immediately after with three ounces of 95° F. The after-spraying with water of a higher temperature dilates the capillaries and this induces a consequent loss of considerable body-heat.

Thus in a tuberculous subject whose evening temperature would at times reach 104° the author reduced the same to normal by using somewhat over one pint of water of from 59° to 66° F. The temperature was with ease kept for four hours at this standpoint and then gradually allowed to rise, but not allowed to reach its former high standing.

Compared to the ordinary method of bathing, this treatment has the advantages of simplicity and comfort, factors not to be disregarded in private practice. The patient simply remains in bed, coverings and shirt are removed, a rubber or wax-cloth laid under him, and the *modus operandi* proceeded with. As each application does not require more than twenty-five minutes, it can be repeated several times daily.—*Prager med. Wochenschrift*, March 20, 1889.

CATGUT RINGS AS A SUBSTITUTE FOR BONE PLATES IN LATERAL ANASTOMOSIS OF THE INTESTINES.

IN the *New York Medical Journal* of March 23d, Dr. ROBERT ABBE has reported another case (in addition to the four already reported by Senn) which illustrates admirably the value of lateral anastomosis of the intestines, and suggests what we think will prove an important addition to our means of effecting it.

The case was one of carcinomatous obstruction in which, under cocaine anæsthesia, Abbe opened the abdomen and found the colon distended to eight or ten inches in diameter. A temporary artificial anus was established, giving escape, according to the author's "moderate estimate," to twenty-five or thirty pounds of feces, including in it fish-bones, cherry-stones, grape and melon seeds, large fragments of bone the size of the finger-nail, together with scraps of oakum, yarn, and wood-shavings. In six weeks after this relief, an operation was done to overcome the stricture. This was effected in the ordinary way by the use of Senn's decalcified bone plates, the seat of the stricture, which proved to be cancer, being in the ascending colon.

The most important point, however, in Abbe's paper, is his suggestion of the substitution of catgut rings for Senn's plates. These plates are admirably made, and can be obtained from Milwaukee, but if one desires to make them for one's self, it involves a number of days and considerable labor. Unless, therefore, the operator has them always on hand, or the case can wait, serious embarrassment might arise. Abbe's suggestion is that the heaviest catgut, softened by hot water, shall be wound four times around the ends of three or four fingers, according to the size of ring desired, and then wound over and over again with the same sized gut to hold the primary strands together. Four to six threads are then simply tied around the ring or passed through by a needle. The wall of the bowel is to be penetrated, and the two openings secured in apposition by these threads. They should be used, we think, single, and not double, as shown in Abbe's cut. The advantages of such rings are that they can be made extemporaneously in a few minutes; they are elastic and present a larger opening than Senn's plates, a point of some importance, for the opening in the latter has sometimes been found in practice to become blocked.

But a few days ago Abbe carried out his suggestion in an operation upon a case of fecal fistula not yet published, and the rings were used efficiently. The result of the operation at the end of ten days was admirable, and the rings bid fair to be an excellent substitute for the bone plates. In addition to the threads attached to the rings passed through the wall of the bowel, as advised by Senn, a few Lembert sutures should be applied in the interspaces, perfect approximation being secured in this manner.

Abbe has also suggested in his paper that the two ends of the gut should not be laid side by side with the ends together, but with the ends pointing in opposite directions. The peristalsis then would be in the same direction for both parts, and the current of the feces would be simply switched, as it were, to a parallel side track, thus avoiding considerable contortion of the gut, which Abbe found in one of his experiments on dogs.

In the *Lancet* of March 16th is a striking confirmation of the value of lateral anastomosis furnished in a paper by JESSETT and HORSLEY. They reprint a large number of experiments and give the results as follows: The operation, as at present practised by the Czerny-Lembert suture, gives a mortality of 86.6 per cent., as against 24.99 per cent. of enterorrhaphy by Senn's invagination method, and only 7.69 per cent. by the method of approximation plates. The time required by the Czerny-Lembert method, which necessitates fifty to sixty sutures, was an hour and a half; the method by Senn's plates required only twenty minutes and

needed but four to six sutures. It is with no little pride that we can point to this increased improvement as an American achievement.

FIRST HELP ON RAILWAY TRAINS.

IT is a humane foresight which, upon all large ocean-going vessels, makes ample provision for the relief of accident and sickness among both passengers and crew. This provision might be imitated upon railways so far as to furnish some of the simpler forms of surgical appliances for the first treatment of wounds and hemorrhage, in cases of accident. It will often happen that casualties occur at points distant from cities and the succor of the surgeon, and there will often be a dearth of any kind of dressings or of hemostatics. It would not be a difficult matter to provide all trains with packages containing a tourniquet, lint, and aseptic or styptic applications, having their method of use plainly described upon the wrappers. The employés of railroads are commonly of an intelligent and teachable class, and they—or a portion of them—could, without difficulty, be instructed in the utility of these dressings.

The humane aspect of this proposition is not the only argument for it; it appeals also to the self-interest of the companies, since the damages that are meted out to them in the courts, in consequence of railway accidents, are liable to be laid in heavier sums if the injuries for which they have to pay assume an aggravated form in consequence of delayed treatment. The interests of the trainmen are also involved, since a greater proportion of the injuries that occur happen to them than to the passenger class, and it cannot fail to lighten the anxieties of many of them to know that they will not be absolutely wanting in the means of self-help in emergencies, and all the more so if some one of their own number shall have been taught how to use those means.

A NUMBER of the strongest State medical societies or associations will hold their conventions within the next sixty days: that of Alabama, "the model organization of the South," opened on the 9th inst., at Mobile; Georgia opens on the 17th inst., at Macon; Texas, on the 23d inst., at San Antonio; Michigan, May 9th, at Kalamazoo; Illinois, May 21st, at Jacksonville; and Ohio, May 22d, at Youngstown. The National Association of Railway Surgeons will hold its annual meeting at St. Louis, beginning May 2d; its officers announce that this will probably be "one of the largest gatherings of medical men ever held in this country."

THE Health Commissioners of New York adopted the following resolution last week: "That Drs. T. M. Prudden, H. M. Biggs, and H. P. Loomis, the pathologists of this department, be and are hereby requested to formulate a brief and comprehensive statement regarding the contagiousness of tuberculosis in man, stating therein the evidence of the same, and recommending in the briefest possible manner the simplest means of protection from its influence."

THE Medical and Chirurgical Faculty of Maryland will hold its ninety-first annual session at Baltimore, April 23 to 26, 1889, under the presidency of Dr. John Morris, of Baltimore. Prof. William Osler, of the Johns Hopkins University, will deliver the annual address, on "The License to Practise," with special reference to State Boards.

DR. CRAIK, Emeritus Professor of Chemistry, has been appointed Dean of the McGill Medical Faculty, in place of the late Dr. Howard, and Dr. George Ross, Vice-Dean. Dr. Ross has also been transferred from the Chair of Clinical Medicine to that of Practice of Medicine. Dr. Richard MacDonnell becomes Professor of Clinical Medicine.

AT recent commencements the degree of Doctor of Medicine was conferred as follows: University of Maryland, 110; University of Buffalo, 46; Atlanta Medical College, 43; Southern Medical College, Atlanta, 35; Medico-Chirurgical College, Philadelphia, 30; Beaumont Hospital Medical College, St. Louis, 22; St. Louis Medical College, 15.

THE following changes have occurred in the corps of teachers of Bellevue Hospital Medical College: Dr. E. L. Keyes has resigned the Chair of Genito-urinary Surgery, Syphilography, and Dermatology, and Dr. Samuel Alexander, of the Class of 1882, has been appointed to fill that chair. Dr. Carlos F. Mac Donald, Superintendent of the State Asylum for Insane Criminals, at Auburn, of the Class of 1869, has been appointed Professor of Mental Diseases.

THE Governor of the State of New York has nominated Dr. Allan McLane Hamilton to be Health Officer of the Port of New York. It is reported that the policy of "hanging-up" the nomination will be

followed in the State Senate so as to prevent the removal of Dr. W. M. Smith, the present incumbent.

It is stated that nearly one hundred and fifty Americans have been attending medical lectures at Vienna during the past winter.

It is proposed to raise an endowment fund of $100,000, to be called the "C. R. Agnew Memorial Fund," the income of which shall be applied to the running expenses of the Manhattan Eye and Ear Hospital. It is believed that there are many friends of the late Dr. C. R. Agnew who will gladly contribute to this fund to mark their sense of his own generous nature, and to aid an institution which he founded and cherished with self-denying care.

The *Brooklyn Medical Journal* for March points with satisfaction to the financial failure of a patent medicine known as the "Scotch Oats Essence." The effects of the company were recently sold out in New York City, under the hammer of the sheriff, sixty-three gross of the nostrum selling for four cents per bottle, the price of which at retail had been one dollar formerly. The downfall of this dangerous and extensively advertised patent medicine was brought about primarily by an analysis by Dr. Eccles, of Brooklyn, by which it was made known that morphia was its efficient ingredient. The unassisted efforts of a private practitioner were thus the means of a palpable victory over quackery. It would be well if a prize fund could be established for the recognition of such life-saving action.

The Clinical Institute of Professor Ziemssen, at Munich, is a noteworthy feature among the educational institutions of that city. It forms a wing to the medical side of the hospital, and is sufficiently spacious to accommodate an out-door clinic and an elaborate provision for exhaustive clinical research. It was built six years ago, according to plans devised by Ziemssen himself, his object being not so much to give additional means for study to the average student as to promote original clinical work. It is sustained by an annual grant of three thousand dollars. It has a suitable lecture-room, with laboratories for medical chemistry, microscopy, bacteriology, and electrical experimentation of every kind. It also contains an ample reference library. Herr Ziemssen is autocrat, and with the aid of one regularly appointed assistant, gives direction to the scientific investigation of the medical cases.

Dr. J. H. Kidder, of the Smithsonian Institution, and formerly of the Navy, died in Washington, last Monday, of pneumonia, aged fifty years. Dr. Kidder was a native of Maryland. He graduated at Harvard, and then entered the Navy as an Assistant Surgeon, continuing in the service until about six years ago, when he resigned. During the latter part of his connection with the Navy he was detailed for duty on the Fish Commission under Prof. Baird, where he remained until the death of the latter. Since then he has been Director of the International exchanges in the Smithsonian Institution. Dr. Kidder was a chemist of high rank, and in that field did some excellent work at the Institution.

Dr. Charles J. B. Williams, Physician-Extraordinary to the Queen, died at Cannes on March 24th, in the eighty-fifth year of his age. For nearly thirty years prior to his retirement from active professional work in 1875, Dr. Williams held a leading place among the London consultants. He was the first President of the London Pathological Society, of the New Sydenham Society, and in 1873 he was elected President of the Royal Medical and Chirurgical Society. He was the author of well-known works on the *Diseases of the Chest*, on the *Principles of Medicine*, and on *Pulmonary Consumption*. He also took an active part in the formation of the Hospital for Consumptives, at Brompton.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, April 4, 1889.

The President, Alfred L. Loomis, M.D., in the Chair.

Dr. T. Gaillard Thomas read a paper on

ACUTE MANIA AND MELANCHOLIA AS SEQUELÆ OF GYNECOLOGICAL OPERATIONS.

(See page 396.)

Dr. James B. Hunter said he was personally cognizant of several cases, including two or three of the more remarkable ones reported by Dr. Thomas, and he could say that the author had underrated rather than overrated the peculiarities of the cases. He thought Dr. Thomas was correct in supposing that gynecological surgery was not more liable to the accident than other surgery. He was present a few nights before at a meeting where the relation of cases of this kind had taken place, and all the surgeons present had some cases to relate. He thought the cases might be classified. The first class, and he thought the smallest, included those in which the psychosis was due entirely to the operation. The

second class included patients in whom there was a predisposition to the development of some nervous trouble, and in whom the operation served to light up the disease. The third class included those in whom the disease developing at the time of an operation was a mere coincidence, and with or without the operation the mental trouble would have progressed. Such cases could not be easily discriminated beforehand. He had one case in which the mania developed a year after removal of an ovarian tumor. He was unable to say whether there was any connection between the operation and the insanity.

There was still another class of cases, alluded to by Dr. Thomas when he spoke of the possibility of iodoform poisoning. This class included all those cases in which the mental symptoms were dependent upon some drug used during the operation, as iodoform, bichloride, carbolic acid, etc. A small quantity of iodoform would develop acute mania in some patients. He also thought that in some patients predisposed to insanity ether might bring on an attack. His impression was that the psychological condition should not interfere with operating. Then there were severe nervous diseases, as epilepsy, which were sometimes cured by an operation. He thought there was some connection between the mental disturbance and the amount of surface exposed during the operation. In operations on the breast and peritoneum, there was greater liability to such disturbances.

DR. NICHOLS, President of the Bloomingdale Asylum for the Insane, said that during his term of service, eleven years, there had been but two cases of insanity following gynecological operations in the institution, one being a case operated upon by Dr. Thomas (according to the statement of the patient's friends), the other a case operated upon recently for removal of one ovary. The latter was suffering from a grave type of suicidal melancholia, the former from paranoia or primary delusional insanity. In both an abdominal fistula had remained, which, however, caused no material pain or drain. He thought the whole number of cases reported, twenty-six, was quite small in proportion to the number of gynecological operations. He saw only one or two possible reasons for insanity following gynecological operations, one being prolonged anxiety from contemplating the operation, and the other the exposure of a considerable surface during the operation, as in removal of tumors of the breast and in laparotomies, which caused more shock than where small surface was exposed.

DR. PAUL F. MUNDÉ had first had his attention called to this subject by Dr. Ill's paper. At that time he thought he had seen no cases of the kind, but he was now convinced that one operated upon by him seven or eight years ago belonged to this class. Twenty-four hours after the operation it was necessary to apply the strait-jacket, but the patient recovered. No iodoform was used.

The past winter his attention had been called to the subject again by a case of Dr. Townsend's, and he had had two himself. One was in a woman on whom he operated for an ovarian tumor with a twisted pedicle; she was of rather melancholic disposition, and after the operation she refused to speak for three or four days. The temperature and pulse were normal. The other case was in a patient on whom he performed Alexander's operation and a plastic operation on the walls of the vagina for prolapsus of the uterus. Some hours after the operation the woman became maniacal, requiring the strait-jacket. There was some fever, the pulse was rapid, but there was no sepsis. The patient recovered after remaining maniacal at least a week.

While considering these cases he had been disposed to think that such mental disturbance was more likely to follow removal of the ovaries than other operations. The natural menopause often caused a marked change in the patient's conduct. Might not also the menopause brought on prematurely produce a marked influence? Since the occurrence of his second case, however, he had thought removal of the ovaries had nothing in particular to do with it. It seemed to him that gynecological operations were no more likely to be followed by mania than other operations. He did believe that long meditation and anxiety regarding the operation might have considerable to do with it. Also, that prolonged anæsthesia had an influence. He did not, however, believe that iodoform was a cause, for iodoform was often used in large quantities without producing any maniacal symptoms.

DR. WILLIAM M. POLK said he found himself taking a position somewhat at variance with that of the gentlemen who had spoken. He considered women more predisposed to maniacal disturbance subsequent to operations than men, especially operations upon the genital organs. It had been his experience that they were more emotional, and all must have observed that certain functions of the genital organs in women were associated with a great many mental disturbances. In fact, if he found that a woman presented any abnormal mental action, he preferred not to operate upon her. He said he had been led to this view of the subject from having had three of these unfortunate cases, each one of which ended fatally. They were cases of pure mania, not of drug poisoning. There were several facts which had been advanced in explanation of the development of mania after operations. One was the use of an anæsthetic, but he thought it had not been proven that the anæsthesia had any tendency to cause mania in other subjects, and why should it, then, in gynecological patients? Some had thought the nervous disturbance due to the exquisite sensitiveness of the perineum in the female, while others thought it due in some way to disturbance of menstruation. He was prepared to admit that a patient who had a long time in which to contemplate the knife might be thrown off her mental balance, but he did not think this would entirely account for the terrible picture shown to-night.

One of his three patients had been subjected to Alexander's operation. The autopsy showed nothing in the brain or at the seat of the operation to account for the mania and death. The second case was one of suprapubic hysterectomy in a patient whose mind was much worked upon by jealousy. There was no sepsis. She had a sister who was a little queer. The third case was in a patient whose mind was decidedly affected when operated upon, and she went on to develop violent mania, requiring the strait-jacket.

DR. W. GILL WYLIE could not say that his personal experience would permit him to give very positive evidence on this subject one way or the other. He certainly was not positive that gynecological operations

caused insanity more than other operations. But there were several things which he thought should be taken into consideration. One of the first was that many gynecological operations were performed upon women who were imperfectly developed, and that imperfect development had its influence in predisposing to mental troubles. Perhaps it was a mere coincidence that those who had an imperfectly developed uterus often had an imperfectly developed brain.

He could say this, that he had operated upon quite a number of women who were insane at the time of the operation. One case was of sufficient interest to relate, being that of a woman who showed insane symptoms after the birth of a child. She was transferred to an asylum, was there six months, and was considered incurable. Her husband brought her to New York, and Dr. Wylie treated her for subinvolution of the uterus and erosion of the cervix. After the treatment of the uterine troubles she recovered and returned home sane. During the menstrual periods, however, she showed slight return of the mental symptoms. She had another child, and somewhat similar insane symptoms developed afterward, but he did not see her for twenty months. On reaching New York she became violently insane. He found disease of the tubes and ovaries and removed them, and the patient returned home much improved mentally.

The only case of acute insanity following any of his operations was in a patient who had had a severe form of epilepsy for some years. Whenever he found any evidence of disease about the genital organs he was perfectly willing to operate upon them. He had formerly thought removal of the tubes and ovaries had a tendency to depress the patient mentally, but later observation had about changed that opinion.

One fact which deserved mention was that all forms of chronic uterine trouble were generally attended by disease of the rectum, if not of both rectum and colon, and he had found that treatment of these latter difficulties went far toward correcting nervous disturbances. He recited one marked case of the kind. He did not wish his remarks to be considered final on this subject, he might in the future change the views which he had expressed to-night.

Dr. Townsend, of Albany, related a case seen by him the past winter, one in which he performed salpingo-oöphorectomy on an hydræmic patient. She went along nicely for four days, when the flow commonly following the operation came on, and with it the patient showed marked mental depression. The wound healed by first intention, the bowels moved regularly, the appetite was good, but there was a rapid pulse both before and after the operation. On the evening of the seventh day the patient became hysterical, the next day became melancholic, and in the evening was maniacal, and had to be placed in the strait-jacket. She died in the night in coma, apparently due to exhaustion. He thought the melancholia which first existed might be due to the hydræmia and illy nourished condition of the brain, while the mania might be due to hyperæmia following vasomotor paralysis.

Dr. Landon Carter Gray thought that Dr. Thomas deserved the credit of having described a new genus of insanity, having related six cases and referred to twenty others. Of the six, three were of the type of mania, three of the type of melancholia; but not one of the three of mania was like any of the recognized forms of mania.

There is an idiopathic form of acute mania in which the patient becomes quite violent, but not uncontrollable, and there is an acute form of mania which has been described under the name delirium grave, really in all probability a cerebritis. The cases described by Dr. Thomas were like those of delirium grave. This seemed to show that there was a general underlying condition following the gynecological operation which led to the insanity. In Dr. Thomas's cases the insanity came on a certain period after the operation, which would point to some general symptom appertaining to the disease, as drug poisoning or micro-chemical product in the blood, rather than to reflex action. It seemed to him this belonged to what had been called post-febrile insanity, some cases of which were of mania, some of melancholia. In all the cases heretofore described of post-febrile insanity there had been great lucidity of the delusions throughout, and a good prognosis. But four of Dr. Thomas's cases had died, which would be likely to occur in none of the other forms of insanity mentioned, excepting delirium grave. In the latter, nearly all patients had died. He would call the form of post-febrile insanity, described by Dr. Thomas, not mania or melancholia following gynecological operations, but post-operative insanity, which demarcated it from ordinary post-febrile insanity.

The President mentioned the case of a patient of his on whom Dr. Lange operated and removed one kidney. She remained perfectly sane up to ten days after the operation, then developed acute mania, remaining insane three weeks, then recovered, and was now in perfect health.

Dr. Thomas, in closing the discussion, said he was exceedingly obliged to the gentlemen for the kindly way in which they had discussed his paper, and he had really but little to say in reply. Regarding iodoform, he felt that the advantages attending its use hardly justified its employment if it was capable of producing such grave results as had been described to-night. While he employed very little of it, and that dusted along the line of the abdominal sutures which closely coaptated the edges of the external wound, yet he was not able to deny Dr. Hunter's position that even under those circumstances iodoform might produce poisoning. He had had three or four cases of iodoform poisoning in which the patient was of insane mind a few days, but he had not included them in the paper.

With regard to ether being a factor in these cases, he did not think it possible, for in all his experience with it he had not known it to produce insanity. But, if he were permitted to digress a little from the subject, he would say that he had seen such bad results from ether in the way of prolonged vomiting and general discomfort, that he was strongly inclined to believe we ought to give it up in laparotomies, and try chloroform again, as European surgeons were doing.

Regarding Dr. Nichols's remarks as to the seeming rarity of this accident compared with the number of gynecological operations, Dr. Thomas thought the discussion had shown that it was not very rare, for twelve cases had been narrated during the evening in addition to those mentioned in his paper, and one of the twelve was a case operated upon by him, as stated by Dr.

Nichols, and this was the first time he had heard of it. He had been much impressed by the remark made by Dr. Nichols regarding the influence of long anticipation of the operation. It was on account of such evil influence on the mind of the patient that he advised his students always to remove tumors from the female breast, of whatever size and whatever nature. After removal, the microscope would tell the story. Dr. Townsend's case had interested him very much, as it closely resembled two of his own.

He felt like repeating the questions with which he had closed his paper, and expressed the hope that other cases would be reported as they occurred, and that the subject would be investigated more thoroughly.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Stated Meeting, February 6, 1889.

THE PRESIDENT, D. HAYES AGNEW, M.D., IN THE CHAIR.

DR. WHARTON SINKLER communicated the following

CASE OF POTT'S DISEASE FROM INJURY, FOLLOWED BY COMPLETE PARAPLEGIA. TREATED SUCCESSFULLY BY SUSPENSION.

John T., aged eighteen, native of Ohio, was admitted to the Orthopædic Hospital and Infirmary for Nervous Diseases, February 16, 1888. Father and mother both living and healthy. He is the eldest of three children; others are healthy; there is no history of consumption in the family; has never had any of the diseases of childhood; always healthy and strong. In September, 1886, some of his school-fellows "bumped" him against a tree. Acute pain in the spine was produced by this at the time, and afterward, in either sitting or standing, pain was remarked; but when lying on his back he was comparatively easy and free from pain. The pain was first greatest in the epigastrium and radiated thence into the back, down into the legs, and up into the shoulders. About three weeks after the injury, he accidentally discovered a lump in the dorsal region of the spine. Soon after observing this, the lump became very painful and was sensitive to the touch. He continued to sit up and walk, but progressively became weaker, and after the second week in January, 1887, was unable to walk at all. About three months after the injury, he began to lose sensation in the legs; the knees began to get stiff in the spring of 1887. He has been unable to sit up, but was comparatively comfortable in bed.

Condition on admission: Angular curvature at seventh dorsal vertebra; can sit up with the aid of a leather corset which he has worn for some months. He is unable to move the legs at all; knees and ankles generally in a state of rigidity; knee-jerk grossly exaggerated; patellar clonus present; ankle clonus very marked on both sides; toe reflex present (this is very striking on both sides). The condition known as *spinal epilepsy* readily induced; plantar reflex exaggerated; no cremasteric or abdominal reflex can be elicited; sensation is impaired, but is not lost. He can localize and distinguish touch anywhere on legs or feet; no interference with the functions of bladder or rectum. There is no pain in the spine. There is a bedsore the size of a ten-cent piece over the sacrum. The circulation in the legs is poor; the feet are constantly cold. His temperature is above normal morning and evening; varying from 100° to 102° F. in the evening; in the morning, 99° to 100° F.

He was ordered massage, and the cautery was used on either side of the angular curvature. He was also ordered cod-liver oil and milk-punch. A plaster jacket was applied soon after his admission, but as he fainted before the plaster could set, it had to be removed, and in two days a second jacket was applied. This could only be borne for three or four days, on account of interference with respiration; and it was removed on the second day. A third jacket was applied at the end of another week, and in this he was comfortable. The bedsore, however, continued to increase in size and depth.

On March 18th he was suspended by means of a padded leather chin and occipital piece from a bar of iron projecting over the head of his bed. This was placed high enough above the bed to allow him to sit upright upon the bed. He was able to bear the extension for nearly five minutes on the first day. On each subsequent day the time was extended, until he was able to bear the extension for half an hour twice a day. On April 17th, the plaster jacket having been removed on March 29th, ice and hot water were applied to the spine over the region of the curvature, for ten minutes four times each day—the ice and hot water being applied alternately; first the cold, followed by the heat.

May 14, he was placed in a chair, and extension made from a rod attached to the back of the chair and bent over the head. About this time he began to have slight power of motion of the toes; this was followed by power to flex the feet, and to flex the thighs.

June 25, fluid extract of ergot, twenty drops three times a day, was added to the treatment; and this was continued until July 31st.

July 23, the following note was made: Condition much improved; complains of no pain; can move legs, drawing up the knees lying on his back in bed; sensation is improved, but is not perfect; clonus is less, but still marked; knee-jerk still exaggerated; toe reflex still present. The application of heat and cold to the spine was continued until October 18th.

In August he was able to lift the feet from the floor as he sat on the chair. One of Kolbe's spinal apparatuses was applied on July 31st, and he has continued to wear this when sitting up ever since; it is removed when he is in bed.

In the middle of August he could walk a few steps in the wheel-crutch.

In October he began to walk about with crutches. He has continued progressively gaining strength in the legs, and is now able to walk about at pleasure, but has not yet been allowed to dispense with his crutches, although quite strong enough to do so.

He has gained in weight. There is no tenderness over the curvature, but there is no material change in its shape. The reflexes are all still exaggerated, but to a moderate extent; and the tremor of the legs is no longer excited by moving them vigorously.

MONTREAL MEDICO-CHIRURGICAL SOCIETY.

Stated Meeting, March 21, 1889.

THE PRESIDENT, WILLIAM GARDNER, M.D., IN THE CHAIR.

DR. SHEPHERD exhibited a patient on whom he had operated a year ago for the

RADICAL CURE OF HERNIA.

The man, a blacksmith by trade, was forty-five years of age, of intemperate habits and very stout. He had had a swelling in the left groin since boyhood, which always disappeared on lying down. It gradually increased in size and entered the scrotum. It now could only with difficulty be reduced. Two years before had received a severe blow on the scrotum with a bar of iron, from this time the tumor rapidly increased in size and became irreducible. Latterly the tumor has become so large and troublesome that he could not do his work, and with difficulty could wear large-sized trousers. The tumor in the scrotum was larger than a good-sized football. He was sent into hospital and kept in bed some time. Operation for the radical cure of the hernia was advised, and, the man having consented, the operation was performed on April 26, 1888.

An incision some eight inches long was made over the tumor and the sac reached. The sac was found to be very thin, and was with difficulty partially dissected out. Failing to reduce the hernia, the sac was opened. The sac contained all the large intestines with the exception of the cæcum and sections, and nearly all the small, besides a large mass of omentum. Several pounds of omentum were removed after ligature, and then an endeavor made to return the bowels. This was not easily accomplished, the abdominal cavity appearing too small to contain them. After manipulating the intestines for a considerable time without making much impression on the quantity outside the abdomen, the man was suspended by the feet. This enabled Dr. Shepherd to reduce the small intestines first, then the large. The whole time occupied was nearly two hours.

It was found that in reducing the large intestines, pushing them in a certain direction failed to diminish the quantity, but as soon as they were pushed in the opposite direction, they slipped in easily. When all the intestines were returned, the abdomen was as tight as a drum, and it seemed as if it would not have been possible to introduce an inch more of bowel. Having taken so much time in reducing the hernia, Dr. Shepherd decided that it was better to sacrifice the testicle of that side, and so complete the operation as soon as possible. The sac was cut off and the ends of the ligature passed through the abdominal walls, as suggested by Mr. Barker, of London, one through each pillar of the internal ring and then tied together; the canal, which, of course, was of large size, was then closed by two silk sutures which were passed through the conjoined tendon and Poupart's ligament, and the external wound closed with continuous silk suture.

The patient was in fairly good condition after the operation and quickly rallied. Next day there was some pain and tympanites. Small doses of salts were given frequently, and the bowels freely moved. The recovery of the patient was uninterrupted and without special incident. He remained in bed some six weeks after operation, when he was discharged with a sinus still unhealed at the point of drainage. After a few weeks more he returned to his work, at which he has been constantly engaged ever since. There has not been the slightest return of the hernia, but the fistulous opening has never completely closed, and some few days ago Dr. Shepherd removed one of the silk sutures from it.

Dr. Shepherd stated that he brought this case before the Society because of the special interest taken at the present time in this subject. The operation performed was a formidable one, and relieved the man from a very disagreeable tumor which had seemingly interfered with his occupation. The sacrifice of the testicle he did not regret, as he was convinced that in these large herniæ cure could be more readily accomplished if the spermatic cord were cut; the stump helped to close the internal opening. The fistulous opening, he thought, was no doubt due to the silk sutures; one had already come away, and when the other was discharged he had no doubt the fistula would heal.

Dr. Sutherland exhibited a patient on whom he had performed

LIGATURE OF THE COMMON CAROTID FOR ARTERIO-VENOUS ANEURISM.

The patient, a girl, aged twenty-four, was brought to the General Hospital on September 3, 1888, having been accidentally shot in the neck by an ordinary parlor rifle carrying a bullet the size of a pea. The bullet entered the neck midway between the symphysis and angle of the lower jaw on the left side, passed across the neck and was found under the skin two inches below the right mastoid process behind the sterno-mastoid. The right side of the neck was swollen and a distinct pulsation and thrill were felt in placing the hand over the upper carotid triangle. With the stethoscope a distinct bruit could be heard. The thrill and pulsation of the tumor gave one the idea that the affection was an arterio-venous aneurism. The pulsation was arrested by compressing the common carotid in the neck. The patient was kept quiet for a few days, and the tumor and pulsations increasing it was decided to throw a ligature around the right common carotid and then search for the wounded vessel. This was done, but failing to find the vessel, which appeared to be deep (probably the internal carotid), Dr. Sutherland determined temporarily to occlude the carotid by ligating it over a piece of drainage tube after the manner suggested by Mr. Treves, of London, and await results.

The patient did well for several days, but the ligature loosening, the pulsation in the aneurism returned, so the patient was again placed under ether and the carotid was tightened in its continuity above the omo-hyoid. The patient did well, the wound healing by first intention except at the point where the bone drain had been. After three weeks she was discharged from hospital with the swelling in her neck much decreased and with the aneurism cured. The fistulous opening remained until January 12th, when the ligature came away and then the opening rapidly closed.

The patient is at present perfectly well. Dr. Sutherland stated that with regard to the tying of the ligature over the rubber tube outside, it was a practice he would not repeat. Although it had the advantage of accustoming the brain to a lessened supply of blood, yet he considered that the retarded flow of blood in the main vessel might lead to a thrombus being formed in some of its anastomotic branches and so interfere afterward with the nutrition of the part. He preferred ligature of the carotid to temporary compression, as the former was much more certain and not more dangerous.

ESBACH'S METHOD OF DETERMINING PROTEIDS IN THE URINE.

DR. RUTTAN exhibited and explained Esbach's method of determining proteids in urine, and showed how it might easily be applied to ascertain the relative proportion of serum-albumin and serum-globulin in urine. He expressed surprise that this method, though over two years old, was not used more by physicians, as it was extremely easy of application and occupied little or no time. It was time that the unscientific and misleading statements which appear in the journals, regarding the qualitative relation of albumin in urine, were replaced by more accurate and reliable observations. Such statements as thirty or forty per cent. by volume of albumin conveyed no information whatever, as to the actual quantity of proteids, nor even of the relative proportion from one observation to the next.

Dr. Ruttan said that it was obvious that the volume of precipitated albumin depended on whether precipitated in flakes or in granules, and this again depends on the time it is boiled and the amount and nature of acid used; again, the specific gravity of the urine, the time elapsing before the observation is made, etc., all should be constant and should be stated, before it is possible by the old method to convey even an approximate idea of the actual amount of albumin in the sample of urine. Esbach's method, though not absolutely accurate, is more nearly so than any other clinical method and has the advantage of giving the actual proportion of albumin by weight in any given sample of urine. Dr. Ruttan also referred to Dr. Grainger Stewart's observations on the significance of the relative proportion of serum albumin and globulin in urine. These observations, though few in number, go to show that the globulin, if in excess or present alone, is significant of functional albuminuria.

NEW YORK NEUROLOGICAL SOCIETY.

Meeting of March 5, 1889.

THE PRESIDENT, GEORGE W. JACOBY, M.D., IN THE CHAIR.

DR. CHARLES L. DANA reported two cases of

FOCAL LESIONS OF THE TEMPORO-SPHENOIDAL LOBE, WITH SYMPTOMS OF FORCED MOVEMENTS.

The first was a case of abscess of the right temporal lobe occurring in a woman of thirty-two years. It resulted from a fall on the head and developed slowly in the course of two years. The notable symptom, aside from headache and a hysterical mental state, was sudden forced movements causing the patient to fall back and to the right. She was continually falling out of bed on the right side, and would sometimes perform *manege* movements. She died suddenly. Autopsy showed an old circumscribed abscess of the third and fourth right temporal convolutions with a recent hemorrhage into the cavity, bursting into the lateral ventricle.

The second case was one of focal meningo-encephalitis causing deep and extensive softening of the second and third right temporal convolutions. The patient, a man of forty, was brought into the hospital in a condition of delirium. A history was obtained of an apoplectic stroke one year before. Since then he had had frequent attacks of dizziness and muscular twitchings during which he would fall always forward and to the right.

A third case of abscess of the right temporal lobe, recently reported in the *Provincial Medical Journal*, was cited, in which the patient frequently staggered to the right.

Physiologists found a number of parts of the brain, irritation of which caused forced movements—*e.g.*, the cortex cerebri, the basal ganglia, the cerebellar peduncles, etc. Pathologists had found in cases of forced movements, lesions chiefly in the cerebellar peduncle, especially the middle; but there were a few observations showing such disturbances from lesions of the parietal lobes. It was suggested that the temporal lobes contained representation of our sense of space and appreciation of changes in bodily position. It might be that the right lobe was especially concerned. There was some *à priori* probability that the vestibular or space-sense root of the eighth nerve and the cochlear or auditory root were connected with neighboring areas in the brain cortex. Anatomically it was known also that the temporo-occipital lobe was connected by a bundle of fibres with the pons nuclei and the cerebellum.

DR. GRAY said it was true that the auditory nerve subserved the senses of hearing and space, and it was quite true that deaf-mutes are never sea-sick, yet lesions of the temporal lobe thus far have produced only word-deafness. These were lesions of the first and second convolutions. We now know that the auditory nerve has connections with the cerebellum. Such profound disturbances as existed in Dr. Dana's cases are generally due to disease of the cerebellar peduncles or semicircular canals. Autopsies seem to have excluded cerebellar lesion, but no mention was made of any examination of the internal ear to see if the canals were normal. He referred to a case of his own with lesion of the temporal lobe with neither word-deafness nor loss of equilibrium. If Mr. Dana's conclusions were correct he had opened up a new field in brain pathology.

DR. FISHER described some of his recent experiments on dogs. Injury to the parietal or temporal lobes he had found to cause rotation to the side of the lesion quite as much as if the cerebellum were involved. These movements would last for several days. His researches therefore in an experimental direction would tend to corroborate Dr. Dana's clinical deductions. His operations were excision of the cortex in places, with more or less laceration.

DR. SACHS thought the most important fact that Dr. Dana had sought to establish was the termination of the vestibular branch of the nerve in the fourth and fifth temporal convolutions, whereas other authors had located all auditory terminations within the first and second temporal convolutions.

DR. DANA, in closing, stated that he had made a gross examination of the internal ear, but had found no sign of inflammatory change. The cortical area for the cochlear branch would remain the same, but the district for the vestibular branch he believed to lie lower down in the temporal lobe.

CORRESPONDENCE.

THE TREATMENT OF SPASMODIC CROUP.

To the Editor of The Medical News,

Sir: In perusing the very interesting article by Dr. Arthur V. Meigs, in your issue of March 23d, upon the subject of the "Treatment of Spasmodic Croup with Opium," it occurs to me to submit to you and your readers my own view of the treatment of this ubiquitous affection. I esteem the emetic as an indispensable introduction to the treatment of *all* cases. Almost invariably the last meal taken is found to be cast up undigested, and oftentimes food that has been taken twelve hours or more before the administration of the emetic. I regard this condition of the stomach as bearing a causative relation, by reflex action, to the laryngismus, and hence administer the emetic *at once*, whether or no the dyspnœa be urgent. Ipecac, I think, is the best emetic for this purpose. It is reliable and mild in its action. When emesis has ceased, I give from two to four grains of quinine, and as large a dose of the *fluid extract of gelsemium* as the age of the child will justify, generally from five to ten drops. The following morning I have the patient take a dose of castor-oil to open the bowels freely, and continue small doses of the gelsemium throughout the day—two drops every two hours. Another full dose of gelsemium and quinine on the second night at bedtime will be effectual in preventing any further paroxysm.

I find imperfect bowel action so commonly preceding these cases, and digestive incompetence or perversion accompanying them, that complete evacuation of the *primæ viæ* seems to me always to be rationally indicated. The administration of opium, as recommended by Dr. Meigs, may subdue the laryngismus by reducing the perceptive power of the nerve centres to morbid irritation, but at the same time the overloaded alimentary canal is rendered *more* inactive, and the digestive disturbance is ignored. These conditions of functional inactivity and perversion are my main points of attack. I regard the laryngismus as their reflex expression or effect upon the sensitive nervous system of the child, and find gelsemium and quinine adequate to allay it.

Yours truly, J. P. Reynolds.

March 30, 1889.

A BONY FALX CEREBRI.

To the Editor of The Medical News,

Sir: In perusing The News of March 23, 1889, I noticed the report of a very interesting case by Dr. Sneve of an osseous growth in the falx cerebri; which reminds me of, and causes me to report in brief, a similar and more interesting case, also one of acute ulcerative endocarditis, which came under my observation very recently.

Case I.—A negro, aged forty years, weight about one hundred and thirty pounds, not emaciated, a laborer, of temperate habits, came into the City Hospital, February 12, 1889, suffering from rheumatism of syphilitic origin as determined from the history of the case, cicatrices on glans penis, and enlargement of the epitrochlear and post-cervical lymphatic glands; pulse 120, temperature 101° F., complained of pain in left side and severe headache; he would lie on his back, eyes widely opened and pupils dilated, and head very much extended—his tongue was coated with a white fur. He was put on 10 gr. doses of iodide of potassium, three times a day; on the second day he manifested spasmodic action of the voluntary muscles, and on the third day he had decided convulsions at short intervals, and on the eve of the third day had stertorous breathing, frequent convulsions, coma and death.

Necropsy: Bones of cranium very thick—dura mater not adherent to the calvarium; the anterior two-thirds of the falx cerebri was ossified and thickened, the plate of bone resembling a scythe-blade, about four inches in length, one inch wide and one-half inch thick at the anterior extremity, and one-half inch wide and one-quarter inch thick at the posterior extremity; the superior border was thin and attached to the cerebral meninges, and the inferior border thin and free in the longitudinal fissure. The surfaces of this plate of bone were rough, presenting elevations and depressions and covered by a very thin layer of modified dura mater. The pia mater seemed thickened by an increase of new cells, or hyperplasia, and was closely adherent to the surface of the cerebrum, which was very hyperæmic and ill-developed; the third and lateral ventricles were partly filled with an amber-colored fluid. Liver and lungs very much congested; the spleen seemed smaller than normal—no microscopical examination of any of the parenchymatous organs was made. I ascribe the death of this man to syphilitic hyperplasia of the pia mater and not to the pressure of this bony falx.

Case II.—A negro, aged thirty-seven, average stature, a laborer, entered the Hospital, suffering from dyspnœa; his extremities and eyelids were œdematous; appetite good; pulse slow, forty per minute—full and compressible; no bruit could be heard on auscultation; temperature, 101° F. He was put on tr. digitalis, tr. iron, and phosphoric acid (dilute), and on the evening of the first day had a marked chill with rigors, followed by temperature of 104½° F.; on the morning of the second day he became delirious—urine was suppressed for thirty-six hours, the last passed contained no albumin or sugar; on the evening of the second day he became comatose and died.

Autopsy: Brain normal; liver and lungs very much congested; kidneys small and seemed contracted, but on section the medullary and cortical portions seemed normal to the naked eye—no microscopical examination was made; spleen considerably congested and pressed upon the superior surface of the left kidney and produced a marked flattening of that portion of the gland. The heart was dilated and hypertrophied; the endocardium and valve on the right side presented no signs of disease, but the endocardium of the superior and posterior portion of the right auricle presented an ulcer, circular in shape, and about one-half an inch in diameter; my finger was easily thrust through the auricular wall at this point. Beside this ulcer there were two other smaller ones near the left side of the auricle—the endocardium of the left ventricle showed no signs of disease; the ulcerative tissues were not examined microscopically for bacteria, nor was the blood.

Finding no other lesions than the above named, sufficient to cause death, and recalling the chills, rapid sinking, and these ulcers on the endocardium, I concluded that the patient died of acute ulcerative endocarditis, occurring not as a secondary disease to some other infectious one, but as a primary disease.

W. R. Jackson, M.D.,
City Hospital, Mobile, Ala.

March 23, 1889.

SUPERNUMERARY DIGITS.

To the Editor of THE MEDICAL NEWS,

SIR: In THE MEDICAL NEWS of March 16, 1889, Dr. W. A. De Wolf Smith, of New Westminster, B.C., reports a case of supernumerary digits in which the variation seems to have originated with the female. He reports this case "in the hope that it may give some assistance in clearing up the question raised by Dr. T. Wesley Mills, in *The Canada Medical and Surgical Journal*, for May 1887." Prof. Mills there states that, according to Prof. Brooks, variations originate with the male, but himself gives a case which is, at least, an exception to the rule, and, as he says, is much against the theory. I beg leave to report the following cases of supernumerary digits which go further to prove that Prof. Brooks' theory does not always hold good.

CASE I.—In the spring of 1888 I was called to see a female negro baby, three weeks old, which had on either hand, opposite the metacarpo-phalangeal articulation, a supplementary finger attached by a pedicle of flesh and skin. The second and third phalanges and the nails of these *extra* fingers were fairly well developed. I removed, with a pair of blunt-pointed scissors, these appendages without any trouble. The parents of this child, who knew the histories of their families as far back as the grandparents, told me that there had been no other case of the kind in either family.

CASE II.—I had a friend who at birth had on each hand six fingers, and on each foot six toes. The supernumerary fingers were removed, but the toes were allowed to remain. These supplementary toes were thoroughly developed, having each a nail, three phalanges, a metatarsal bone and perfect articulations. He was the only member of his family, the history of which both on the paternal and the maternal side, was well known as far back as the grandparents, who had either supernumerary fingers or supernumerary toes. He had five sons, all of whom had normal hands and feet. In fact, he was the only member of this entire family who had an abnormity of any kind.

WILLIAM F. DREWRY, M.D.,
CENTRAL LUNATIC ASYLUM, PETERSBURG, VA.

AUTOMATIC AMBULATION.

IN THE NEWS of March 23d, a letter on the above subject was printed, from Dr. F. Donaldson, Jr., describing intelligibly that remarkable case of M. Charcot. A recent issue of the *London Medical Press* treats of this case and enters a caution that is worthy of quotation: "Extraordinary as it may seem, we have not to go far to find in ourselves the parallel [of this muscular automatism] for under the influence of a dominating train of thought, or strong emotion, perception is practically suspended, although there may be no outward evidence of its temporary abrogation. One is justified in preserving a certain scepticism in these matters short of scientific demonstration, as otherwise one might involuntarily connive at the spread of a pseudo-malady to which Parisian *changeurs* seem peculiarly subject, the principal symptom of which is a liability to take the train to Belgium without being conscious of the risk that their sudden disappearance, with the funds intrusted to their care, may be misinterpreted. Automatons of this kind are likely to prove very troublesome members of society, and unless they are enabled to foretell the advent of the attacks by the aura, it would be well to place them *nolens volens* under a suitable restraint."

The above admonition can, without much straining, be adapted to this country and climate by substituting Canada for Belgium and "boodlers" for the Parisian defaulters of whom the editor writes. It can hardly be expected that every automatic ambulator will fall into the hands of so keen an observer as Charcot and from him receive a certificate as a measure of safe-conduct, but it is desirable, at least, that whenever they may be discovered that each case of the kind shall be refused passport and, if practicable, be labelled "not to go out of the country," pending a thorough medical examination. W.

VERMONT AND SOUTH CAROLINA IN 1827.

To the Editor of THE MEDICAL NEWS,

SIR: I chanced this morning to take down a bound volume of pamphlets, pertaining to medical education, from one of which I wish to quote briefly. It is a tract of twelve pages, called "Proceedings of a Convention of Medical Delegates held at Northampton, in the State of Massachusetts, on the 20th day of June, 1827." The convention was the result of an effort on the part of the State Medical Society of Vermont to improve the status of medical education in the northern States; it laid the foundation of "an Association of Medical Societies and Institutions;" it made a code of rules calling for a high standard of qualifications; it was, in essence, a premature budding of the American Medical Association, limited to the north-eastern States—inclusive of New York—because of the then limited means of transportation; the American Medical Association came into being about nine years later, at a time when great relative improvements in travel had been acquired. I quote:

"It would have been highly gratifying if this convention could have been composed of delegates from all the States in the Union. But the blessings of our extended territory are not without inconveniences. It would seem nearly impossible that persons from such distances should be brought together with any convenience and continue in session long enough to consider all the local customs and circumstances which ought to influence the regulations to be adopted in such a case; nor would it be easy in any way to reconcile all the different habits and practices of the people of such distant territories as those which are occupied by our nation. Meanwhile we doubt not that the zeal in the cause of medical education is as great in the other States of the Union as in those which we represent. The Medical Institution of Charleston, S. C., has very honorably manifested its desire to elevate the profession in the only proper way, by making it more learned and more useful."

Among the eleven names of delegates who sign the report appear those of some of the veterans in the New England schools, such as R. D. Mussey, James Jackson, H. H. Childs, and Usher Parsons.

Thus it will be seen that while Vermont takes the initiative in the good cause in the north-eastern States, she is not able to steal the march on the "institutions" of the South; this word *institutions* was then used throughout New England in regard to colleges of medicine, and had no reference to associations or societies. No State other than South Carolina is mentioned by

name, in this report of proceedings, as being in earnest for the advancement of medical education; it unfortunately omits to specify what particular action, taken by the South Carolinian College, it was that won for the latter this honorable mention.

The convention ordered the printing of an edition of five thousand copies of these *Proceedings*. This was done at Boston, in 1827, under the eye of a committee of which Drs. Warren and Jackson were members. This pamphlet is sufficiently rare to have escaped inclusion in the Library of the Surgeon-General—at least, the volumes of the *Index-Catalogue*, at my command, have not yielded it to my search. Yours, with respect,

ALBEMARLE.

OBITUARY.

ROBERT PALMER HOWARD, M.D.

DR. ROBERT PALMER HOWARD, Prof. of Medicine and Dean of the Medical Faculty in McGill University, whose death was noticed in our last issue, was born in Montreal, January 12, 1823. He graduated in medicine at Montreal in 1848, and then studied in Dublin, London, Edinburgh, and Paris. In Dublin, he had the advantage of a prolonged course of instruction under Drs. Graves and Stokes, from whom he probably acquired that enthusiasm in the study of clinical medicine which distinguished him throughout his long career. He returned to Montreal in the latter part of 1849, and at once entered upon practice. In the early part of his career he was, for several years, connected with the St. Lawrence School of Medicine, an institution which had but a short existence. In 1852, he became one of the Demonstrators of Anatomy; in 1854, Prof. of Medical Jurisprudence; in 1856, Prof. of Clinical Medicine; in 1860, Prof. of Medicine in the University.

In 1882, on the death of Dr. Campbell, he became Dean of the Medical Faculty. For twenty-four years he was physician to the Montreal General Hospital, and served as Secretary to the Corporation. He held very many positions of honor and trust in the profession and in the community. For nearly thirty years he was one of the Governors of the College of Physicians and Surgeons of the Province of Quebec, and had been President of the same. He was President of the Canada Medical Association and of the Medico-Chirurgical Society of Montreal.

His contributions to medical literature were very numerous, and are to be found, chiefly, in the *British-American Journal*, in the *Montreal Medical Chronicle*, in the *Canada Medical and Surgical Journal*, and in *The American Journal of the Medical Sciences*. His writings upon phthisis have been numerous and valuable, and he was among those who upheld the unity of this disease at a time when Niemeyer's views were universally prevalent. His paper upon pernicious anæmia, read before the International Medical Congress at Philadelphia in 1876, was one of the earliest and most valuable contributions on this subject. His latest communications were upon hepatic cirrhosis in children and ophthalmoplegia externa.

As a teacher of medicine for thirty-three years, Dr. Howard enjoyed a unique reputation in his own country. To him was due, in great part, the development of that admirable and systematic plan of clinical instruction which has prevailed for so long in the Montreal General Hospital. Painstaking, logical, systematic, thoroughly versed in morbid anatomy, he was not only a model instructor, but he had that earnestness which at once commands the respect of, and affords the greatest stimulus to, the student. His work in connection with the development of higher medical education in Canada was consistent and progressive. For years he labored to introduce into the Dominion a medical bill which should require a minimum standard for practitioners in all the Provinces. This was found to be impracticable, and, of late years, his energies have been directed to the strengthening and advancement of the Medical Board of the Province of Quebec.

His fatal illness overtook him in the full tide of professional and college work. On Saturday evening, March 16th, he was taken with a heavy chill consequent upon exposure; on Tuesday, the 19th, signs of pneumonia developed, which increased rapidly and proved fatal on Thursday morning, March 28th.

NEWS ITEMS.

An International Congress of Therapeutics and Materia Medica will be held at Paris from August 1 to 5, 1889, in the hall of the Sociétés savantes, No. 28, Rue Serpente. All physicians, pharmacists and veterinary surgeons, sending in their names and paying the assessment of ten francs (two dollars) will be permitted to take part. The Congress will be divided into two sections: one on therapeutics and the other on materia medica.

The committee of organization is composed as follows: Drs. Moutard-Martin, president; Dujardin-Beaumetz, vice-president; Constantine Paul, secretary-general; P. G. Bardet, assistant secretary-general; Labbé, secretary of the section of therapeutics; R. Blondel, secretary of the section of materia medica.

The following subjects will be discussed:

1. The antithermic analysis. M. Dujardin-Beaumetz, reporter.
2. The antiseptics proper for each species of pathogenic microbe. M. Constantin Paul, reporter.
3. Heart tonics. M. Bucquoy, reporter.
4. The new drugs of vegetable origin recently introduced in therapeutics. M. Planchon, reporter.
5. Unification of weights and measures used in formulas; the advantages of an international pharmacopœia. M. Shaer, of Zurich, reporter.

An exhibition of drugs will be held during the session of the Congress in the same building and under the direction of Drs. Adrian and Blondel.

All communications should be addressed to Dr. Bardet, Assistant Secretary-General of the Committee of Organization, No. 119 bis, Rue Nôtre-Dame-des-Champs, Paris, France.

The Royal Victoria Hospital, Montreal.—The drawings for the new Royal Victoria Hospital, Montreal, Canada, have been received trom London. The central, or main, building consists of four blocks, the front one, on either side of the entrance hall, being devoted to the nurses' apartments, and those of the lady superintendent and matron, together with the general offices. The block

behind this consists of a building, the shape of a Latin cross, devoted to the clinical department, with a separate entrance for the students. Behind this again are two other blocks, containing three theatres and the mortuary, and at the rear of these, but perfectly isolated from them, is the ice house. The wing on the left hand, or western side, consists of three blocks, each four stories high, with, between them, small buildings containing the staircases, each ward communicating therewith by means of covered galleries. The accommodation to be provided is—surgical patients, about 90 beds; medical patients, about 180; private paying patients, about 20; total, 290 beds. Infectious hospital, about 35; total, 348.

At the rear of the buildings is the infectious hospital, conducted upon the hut system. The whole building will cost about half a million dollars.—*Boston Med. and Surg. Journal*, April 4, 1889.

The Operating-room at the Hotel Dieu, in Lyons.—The new operating-room at the Hôtel Dieu, in Lyons, which has recently been opened for use, would appear from a lecture delivered by Prof. A. Poncet, who has charge of the teaching in operative surgery, to be one of the most completely aseptic operating-rooms to be found. M. Poncet has had it constructed according to designs of his own, elaborated after a visit to many of the hospitals in England, France, Germany, Austria, and Switzerland.

The two objects he set before himself were the prevention of infection by means of air or through contact. It is about thirty feet in length by twenty feet in breadth, the height being about twenty-four feet. As its situation beneath the wards rendered a skylight impossible, the light is admitted by one immense window, the eight panes of which are made to open. Artificial light, when required, is obtained from a Wenham gas-lamp, which can be lowered to within about seven feet of the ground. The walls are covered to the height of five feet with glass, forming a dado; above that with perfectly smooth stucco of a rose-gray tint. All the angles are rounded. To the walls are fixed nickelled brackets supporting shelves of plate glass, which, however, do not come within half an inch of the wall; on these shelves stand vessels containing antiseptic solutions, and ingeniously constructed metal receptacles for dressings. The ceiling is in the form of a dome, and the floor, which is of cement, slopes slightly to an aperture in the centre leading to a carefully constructed drain. The surface is channelled, and is washed down daily, also once a week with carbolized water.

The few chairs and benches are made of bronzed iron; the tables are made with glass tops and metal frames, and are provided with casters. The operating-table is entirely free from the complicated mechanism frequently seen, and the top, which is of glass, is, like the floor, made to slope toward the centre, where there is an aperture communicating with a drainage-tube. The mattress is covered with mackintosh, and is perforated so as to allow of drainage. When the patient requires to be propped up, pillows and cushions covered with mackintosh are used, to the entire exclusion of mechanism. Ingenious arrangements are made for the reception of the anæsthetist's and the surgeon's appliances, and a second table is provided for operations requiring the operator to stand between the patient's thighs.

The instruments, whose handles are specially made with a view to prevent any difficulty in cleaning, are all washed in glycerine at the temperature of 120° C., and then kept in carbolic solution.—*Lancet*, March 23, 1889.

In Memoriam.—At a meeting of the Medical Staff of the Philadelphia Hospital, held April 1, 1889, the following was adopted:

WHEREAS another vacancy on our Staff has been created by death;

Resolved: That by the death of DR. EDWARD T. BRUEN, who was an indefatigable worker, a clear thinker, and an able writer, the interests of scientific medicine have suffered severe loss.

Resolved: That while this loss will be felt by every medical practitioner, it is but slight compared with that experienced by numerous personal friends, to whom he had endeared himself by many amiable qualities.

Resolved: That the sincerest sympathy of the Staff of this hospital be tendered to the family of their late colleague.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 2 TO APRIL 8, 1889.

ALDEN, CHARLES H., *Lieutenant-Colonel and Surgeon* (U. S. Army).—Detailed as a member of the Army Medical Board, to meet in New York City, May 1, 1889.—Par. 5, *S. O. 74, A. G. O.*, March 30, 1889.

MCELDERNEY, HENRY, *Major and Surgeon* (U. S. Army).—Detailed as a member of the Army Medical Board, to meet in New York City, May 1, 1889.—Par. 5, *S. O. 74, A. G. O.*, March 30, 1889.

MATTHEWS, WASHINGTON, *Captain and Assistant Surgeon* (U. S. Army).—Detailed as a member of the Army Medical Board, to meet in New York City, May 1, 1889.—Par. 5, *S. O 74, A. G. O.*, March 30, 1889.

MERRILL, JAMES C., *Captain and Assistant Surgeon* (U. S. Army).—Detailed as a member of the Army Medical Board, to meet in New York City, May 1, 1889.—Par. 5, *S. O. 74, A. G. O.*, March 30, 1889.

By direction of the Secretary of War, JOSEPH R. GIBSON, *Major and Surgeon*, is relieved from duty at Fort Lyon, Colorado, and ordered to Fort Sheridan, Illinois.—Par. 11, *S. O. 77, A. G. O., Washington*, April 3, 1889.

By direction of the Secretary of War, A. H. APPEL, *Captain and Assistant Surgeon*, is relieved from duty at Fort Sheridan, Illinois, and ordered to duty at Fort D. A. Russell, Wyoming Territory.—Par. 11, *S. O. 77, A. G. O., Washington*, April 3, 1889.

By direction of the Secretary of War, GEORGE H. TORNEY, *Captain and Assistant Surgeon*, is relieved from duty at Fort Monroe, Virginia, and ordered for duty to Fort Brown, Texas.—Par. 11, *S. O. 77, A. G. O., Washington*, April 3, 1889.

By direction of the Secretary of War, SAMUEL Q. ROBINSON, *Captain and Assistant Surgeon*, is relieved from duty at Fort Brown, Texas, and ordered to Fort Hamilton, New York, for duty.—Par. 11, *S. O. 77, A. G. O., Washington*, April 3, 1889.

By direction of the Secretary of War, leave of absence for six months is granted to CHARLES S. BLACK, *Captain and Assistant Surgeon*, to take effect after the arrival of Acting Assistant Surgeon Robert P. Finley at Fort Sidney, Nebraska.—Par. 14, *S. O. 18, A G. O, Washington*, April 4, 1889.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY, FOR THE WEEK ENDING APRIL 6, 1889.

MARSTELLER, E. H., *Passed Assistant Surgeon.*—Ordered to the U. S. S. "Adams."

STITT, E. H. (of South Carolina).—Commissioned Assistant Surgeon, U. S. Navy.

GATES, M. F. (of Pennsylvania).—Commissioned Assistant Surgeon, U. S. Navy.

BOYD, J. C., *Surgeon.*—Detached from the Bureau of Medicine and Surgery, Navy Department, and ordered to the "Yorktown."

GATES, M. F., *Assistant Surgeon.*—Ordered to the Navy Yard, Philadelphia.

ON PHAGOCYTES.

An Address
before the Alumni Association of Bellevue Hospital, New York, delivered April 3, 1889.

BY WILLIAM OSLER, M.D.,
PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA.

(Concluded from page 396.)

THE theory elaborated by Metschnikoff had been hinted at by many previous observers, but to him is undoubtedly due the credit of bringing it into prominence, and of doing in connection with it a very large amount of interesting work. It must be allowed that he came to his task well prepared. Many of us can look back with pleasure to his brilliant investigations upon the intracellular digestion in the Planariæ and in Sponges, carried on largely at the Naples Marine Station; investigations the truth of which, so far as I know, has not been controverted. Following these studies, directly in the same line, was his interesting research into the method of the absorption of the tail of the tadpole, already referred to, in which he appears to have demonstrated that the atrophy of this organ results in reality from the active removal of the fragments of the tissue by leucocytes.

So far the work was biological, and had no direct bearing upon the phenomena of disease further than that, in the latter illustration, it bore out the well-known fact of the absorption by leucocytes of foreign bodies placed within the tissues. In 1884, in the 96th vol. of Virchow's *Archiv*, he published a paper[1] which arrested the immediate attention of students in parasitology. It is now too old a story to narrate at length; it will be sufficient to remark that in the daphnia, the common water-flea of the aquarium, he had studied the relation of the leucocytes to a fungus with which these insects are prone to be infected. The phagocytes attack the fungi which enter the body cavity from the intestines, and practically eat them, enclosing them in protoplasm. Where one cell is insufficient, several combine to enclose the spores in large plasmodia-like aggregations—giant-cells. If the invasion was in such large numbers, and the activity of the fungus so great that conidia were formed, the resisting forces were insufficient, victory remained with the enemy, which meant the death of the daphnia. Of 100 insects studied, 73 became infected, of which 59 recovered and 14 died.

Following this line, Metschnikoff proceeded to study the relation of leucocytes to anthrax bacilli, to the micro-organisms of erysipelas, and to various other affections. He likened specific inflammation to a warfare in which the invading army is represented by microörganisms, and the resisting forces by the leucocytes. Even in details the analogy was maintained. Notice of the arrival of the invaders was telegraphed, so to speak, by the vaso-motor nerves; the line of communication, the avenues of mobilization, were represented by the bloodvessels. The aim of the invader is to secure the territory, to multiply rapidly, to live at the expense of his host, and to manufacture and circulate substances injurious to him. The aim of the resisting forces is to encircle the enemy, inclose him, digest him, and render him inert in battle. Many phagocytes die in the process, and, if in large numbers, the heaps of the slain represent pus; an abscess is a battleground densely packed with dead bodies. If victory remains with the invaders the organisms pervade the affected part, multiply, and induce conditions incompatible with the life of the part, or perhaps with the life of the entire organism. If the battle is with the host, the parasites are destroyed, perhaps not without loss, but the normal state is gradually restored. Practically, on this theory each organism is regarded as possessing a standing army composed of mesoblastic cells, capable of rapid reproduction and rapid concentration, one important function of which is to protect the organism against destructive agencies invading it from without. Certainly a most attractive theory, fully deserving the attention which it has aroused. On the one hand widely accepted, on the other bitterly assailed, the question is as yet far from settled, and to the position in which it stands I propose briefly to refer, and then to offer some results of my own observations upon a disease in which special facilities exist for the study of the problem.

Metschnikoff has studied a number of diseases, erysipelas, anthrax, relapsing fever, and tuberculosis, with a view of finding facts in support of this theory, and his communications within the past four years have been numerous and elaborate.[1] They have been so widely abstracted and so often referred to that I shall not occupy your time by entering into details, but will briefly indicate the chief points upon which he lays special stress in these different affections, and note certain of the observations which have been made by other workers.

In erysipelas the cocci are attacked first by the leucocytes filling the lymph spaces, which rapidly proliferate and actively eat the microörganisms. Not alone do the colorless corpuscles act as phagocytes, but the fixed connective tissue cells assist in an important manner. In cases of recovery he found that behind the advancing cocci the leucocytes were crowded with parasites which showed evidences of digestion and destruction. The connective-tissue cells do not appear to attack the cocci, but are chiefly concerned with the absorption of the inflammatory exudate, even taking up the leucocytes which have died. In fatal cases there was enormous development of micrococci, the majority of which lay free in the tissues not enclosed in the phagocytes. Inoc-

[1] Ueber eine Sposspilzkrankheit der Daphnien.

[1] Published chiefly in Virchow's Archiv.

ulations with erysipelas cocci in white rats confirm these observations made in man. The leucocytes attack the parasites, which undergo rapid degeneration in the protoplasm. The larger connective tissue cells, macrophages, did not attack the cocci. Metschnikoff recommends experiments upon these animals with the erysipelas cocci as an especially favorable field in which to study the struggle between the cells and bacteria.

In anthrax Metschnikoff has studied the relation of the phagocytes to bacilli introduced into frogs, which, as is well known, possess immunity at the ordinary temperature, but succumb when the temperature is raised. A graft of a piece of anthrax tissue under the skin of a frog is within from fifteen to twenty hours surrounded by leucocytes, which take up many bacilli. According to Koch, they may grow inside the cells and even burst them, but Metschnikoff holds that the anthrax filaments do not develop within the cell, but are gradually destroyed by them, and that this is the reason why the frog at an ordinary temperature recovers. In the heated frog the bacilli rapidly develop and the efforts of the leucocytes proving insufficient, the animal dies; not, it is asserted, from any inactivity on the part of the leucocytes but because the bacilli secrete a liquid which protects them from attack.

In Baumgarten's criticism[1] he relates some experiments with the anthrax bacilli which directly antagonize these observations. Pigeons do not die when inoculated with anthrax, and he found that the bacilli injected degenerate in precisely the same way in these creatures as when in distilled water; only here and there did the leucocytes contain the rods.

He found that in frogs, though the bacilli are eaten by the leucocytes inversely to the degree of heat to which the animal is exposed, there is never total destruction of the bacilli by the phagocytes.

Hess[2] has performed experiments which bear directly upon these points. Anthrax cultures in Zeigler's glass chamber, inserted beneath the skin in animals not very susceptible to the disease, as dogs and birds, showed active migration of the leucocytes into the chamber which appear to attack the bacilli and to destroy them. These very striking experiments certainly indicate what, of course, is well known, a high degree of activity on the part of the leucocytes, finding their way, as they do, into the chamber closed at all points except one narrow orifice. But, as Hess says, it is a question whether the disintegration in the cells necessarily means destruction by the cells.

In relapsing fever Metschnikoff states that the spirilli are not attacked by the leucocytes in the blood but are destroyed only in the spleen. In the artificially produced disease in monkeys, he finds abundant inclusion of the spirilli in the phagocytes of the spleen during the period of the rise in temperature before the crisis. This, however, may simply mean that the spirilli, most of which gradually disappear from the blood at the crisis, have lived their life and are about to die, and in this state are taken up by the normal splenic phagocytes, just as are the effete red blood-corpuscles. He explains the recurrence of the second, or even of the third, attack of the fever by supposing that certain spirilli remain alive after the crisis and start afresh a new generation, which is not retarded in its growth, as the phagocytes are too busy in digesting the spirilli which they had eaten during the former attack.

An interesting study of phagocycosis has been made by Laehr, a pupil of Ribbert,[1] who has studied the effect of injection into the lungs of rabbits, through the trachea, of staphylococcus pyogenes aureus. Within a few hours the cocci are almost all to be seen within the alveolar epithelium, and in the leucocytes, which latter, in the course of a few days, disappear from the alveoli and pass into the bronchi. Meanwhile, the alveolar epithelium proliferates, causing a catarrhal inflammation. Within the first week the cells contain many cocci, which gradually become less numerous, and in the second week entirely disappear. He looks upon this as a confirmation of Metschnikoff's views.

In a second investigation, Hess[2] has studied, in rabbits and in cats, the relation of the leucocytes to the staphylococcus aureus inoculated in the cornea. At first there is marked increase, which leads to an acute inflammatory process in the neighborhood of the cocci. The leucocytes increase rapidly, and within two or three days almost all of the cocci are within cells. In cases which recover, by the sixth day no cocci are found. When the process does not result in healing, the phagocytosis is slight.

Baumgarten states[3] that experiments made in his laboratory do not confirm these results of Hess.

Ribbert, in his study on the destruction of pathogenic bacteria in the body, supports Metschnikoff's[4] views. He found, after injection of the spores of Aspergillus and Mucor, that they collected in the organs of the experimental animals, particularly in the liver and lungs, and that within a few hours after injection they were surrounded by leucocytes, which either completely prevented or restricted the growth of the germs. Injections in very large quantities might not be sufficient to hinder the growth of the parasites, and the animal died. In the lungs and in the liver the phagocytes are much more active than in the kidneys. Precisely similar occurrences were found where the spores were injected into the anterior chamber, and it is worthy of note that he found on the anterior surface of the iris, in the neighborhood of the pupil, the phagocytes much more active and the disintegration of the spores much more marked than in the posterior part of the iris in contact with the lens. Ribbert holds that the destructive influence of the leucocytes is exercised chiefly by their preventing access of nourishment to the spores (particularly of oxygen), and in favoring, also, an accumulation about them of destructive metabolic products. He regards the fixed connective-tissue cells of the liver, and the giant cells which develop in the liver and in the lungs, as the most important agents in the final destruction of the spores.

As we might suppose, the views of Metschnikoff have met with sharp criticism in many quarters, and from no one more ably and at greater length than from Baumgarten.[5] While not denying that the leucocytes eat the

[5] Loc. cit.

bacteria, he claims that the process is by no means universal, and is carried on so unequally, that we can scarcely speak of an active warfare waged against the parasites.

As a specially weak point, he alludes to the powerlessness of the phagocytes in the Daphnia disease so soon as the conidia are formed from the spores.

In relapsing fever, the freedom from attack which the spirilli enjoy in the blood is urged strongly against the phagocytic theory. The fact that spirilli are found in a number of cells of the spleen toward the crisis simply means that the phagocytes of this organ behave to them as to other foreign bodies. Probably, too, the spirilli begin at this time to lose their vitality, as is shown by their less active movements, and are then readily taken up by the splenic leucocytes in a manner precisely similar to effete blood corpuscles.

In erysipelas, Baumgarten criticises the position in which Metschnikoff finds the parasites, namely, in the second zone, behind the advancing cocci, as conclusively showing that they are not fighters of the battle—not, as he expresses it, "the heroes of the day, but the hyenas of the field."

The observations of Christmas-Derkinck-Holmfeld[1] are also directly opposed to the theory of phagocytosis. He finds in anthrax experiments that very few of the bacilli are taken up by the leucocytes. In rats they degenerate within two or three days after inoculation, and for the most part outside of the cells. He holds that pus formation is a conservative reaction against the penetration of the bacterial germs, but that the neutralization of the action of microörganisms depends much more on the chemico-biological relations of the tissues than on any property of the cells to destroy them by inclusion. His view, in fact, approaches that of Ribbert already referred to, in ascribing the limitation of bacterial growth to nutritive changes, particularly to the restriction of oxygen, rather than to any phagocytic action of the cells.

In Flügge's laboratory, observations have been made by Bitter and by Nuttall,[2] of San Francisco, which directly contradict those of Metschnikoff. Nuttall's elaborate experiments appear to show conclusively that the destruction of the bacilli in the living body is not effected by the phagocytic action alone.

And, lastly, in tuberculosis, the question of the relation of the cells to the bacilli is being carefully studied. In his recent paper on the subject,[3] Metschnikoff claims that the degeneration of the bacilli, which has long been known to occur within the giant cells, results directly from their phagocytic action, and is not a natural decay. Baumgarten, on the other hand, regards the relation of the giant cells to the bacilli as one of the strongest evidences against the theory of phagocytosis.

With the relations of phagocytes to bacteria, I have had so little practical experience that I hesitate to express any positive conviction on the question, but I have, for nearly three years, been working at a problem identical in all its relations, but in which the parasitic bodies belong to a higher class of organisms. I refer to malaria, and to the hæmatozoa which occur in the blood of this disease. A sceptical attitude in these days of hasty observation and of still hastier conclusions is peculiarly appropriate. I complain of no one who, without ample opportunities for personal study, claims the right to question the full significance of Laveran's important discoveries. Perhaps better than any one else, I am in a position to extend sympathy to the sceptic, as, until ample material came to hand in 1886, I was among those who looked upon the work of Laveran with extreme incredulity. The corroboration in almost every detail which his studies have received during the past three years is in all respects remarkable. Working as he did, alone in Algiers, under circumstances the reverse of favorable, without proper laboratory equipment, without the stimulus to be found in the association of men in large cities, it is not only in the highest degree creditable, but most encouraging, that an army surgeon, actively engaged in the duties pertaining to his battalion, could accomplish so thorough a piece of work, requiring but little subsequent correction, and receiving at all hands ample confirmation.

Richard, in France; Marchiafava and Celli, Golgi and his pupils, in Italy; Sternberg, Councilman, James, Shattuck, and myself, in this country; and Vandyke Carter, in India, working far apart, have all practically confirmed, with minor modifications and amplifications, Laveran's observations.

While the invariable association of these parasites with malaria would appear to be settled, their precise morphological relations are still a matter of discussion. I have urged, from their resemblance to other hæmatozoa, that they should be classed with the genus of Hæmatomonas (Metrophanow), which includes all forms of monads parasitic in the blood, of which a considerable number is known among the lower animals. Briefly, to refresh your memory, I may refer to the forms which occur in ordinary malaria. In the acute cases there exist in the red blood-corpuscles hyaline and pigmented bodies which undergo amœboid changes, and which gradually destroy the corpuscles, converting the hæmoglobin into a black pigment. Under certain circumstances, more particularly during the paroxysms, these bodies increase in size, and undergo segmentation, breaking up into a number of small free spherical bodies. In smaller numbers in the blood, but more constantly in the spleen, are the remarkable flagellate organisms. Lastly, in more chronic cases there are the still more extraordinary crescentic forms. Practically, the unanimity which exists in the statements of the observers above named regarding these bodies, places the question of their existence in malaria (and I may say, based upon the number of negative observations, in malaria only) beyond any reasonable doubt.

That they truly constitute the actual germ of the disease is, however, a point upon which opinions may differ. The constancy of their presence, their absence in other individuals in malarial regions, their abundance in the graver forms of disease, the destructive influence they exert upon the blood-corpuscles, are urged by Lavaran in evidence of their pathogenic nature.

However this may be, the question which here concerns us relates to the relation between the phagocytes and these bodies. Surely one might suppose that here, if anywhere, the theory of phagocytosis might receive

[1] Fortschritte der Medicin, 1887.

[2] Archiv für Hygiene, Bd. iv. I would particularly recommend the summary of Bitter's to those wishing further details, and for a striking series of experiments, the paper of Nuttall's.

confirmation or rebuttal. What but phagocytes are the amœboid forms of these parasites which exist in the red blood-corpuscles, gradually destroying the stroma and the hæmoglobin until nothing but a shell remains? Here, indeed, are foemen worthy of the steel, or, rather, of the plasma, of the leucocytes. What, then, are the facts? How far can we say that in the blood in malaria, the seat most assuredly of the chief pathological changes, in acute cases, that there are evidences of a struggle between the phagocytes and the hæmatozoa. It has long been known that the leucocytes in this disease (particularly in chronic cases) contain pigment granules. There is no other affection in which melanæmia is so constant a feature, though it is now and then met with in other conditions. The leucocytes obtain the pigment either in the blood itself, or in the liver, spleen, or marrow, where the red corpuscles undergo their final destructive changes. In an examination of nearly one hundred and fifty cases of all forms of malarial affections, I have looked carefully at this point with a view of determining the exact mode in which the leucocytes obtain their pigment, and in my observations of the past two years the question of their relation to the various forms of the hæmatozoa has engaged my special attention. It may be remarked, in the first place, that there is certainly an increase in the number of white blood-corpuscles, an increase not associated, so far as I know, with any special change in the character of these bodies.

The result of my work in this direction may be stated in a few words. In the blood, at least, there is very slight evidence of the existence of phagocytosis. Here and there, it is true, we meet with leucocytes which have included the amœboid forms of the parasite, either free or still surrounded with the shell of a red blood-corpuscle. I have but three or four sketches in a whole series illustrating this fact. Occasionally a crescent may be seen within the white blood-corpuscle, more frequently the smaller free bodies which result from the segmentation. I have in my paper on this subject, given a sketch of a leucocyte which was watched for an hour and one-half and had included one pigment body, and was about to take a second, behaving identically though more deliberately than its great prototype, the pond amœboid. I confess myself disappointed in this respect. It may be urged that in a blood drop after withdrawal, the conditions are not favorable for study. But the absence of any great number of leucocytes containing parasites in a comparatively unaltered state, shows that certainly in the circulating blood the leucocytes do not actively attack and eat the parasites. More probably, I think, they pick up the pigment granule after the disintegration of the parasite, or in such regions of the circulation as the spleen or the bone marrow where the conditions are more favorable to phagocytic action. Even on the warm stage with the leucocytes displaying for hours amœboid movements, and in specimens which contained "foes" innumerable, it was exceptional to see evidence of active warfare.

It is, of course, more difficult to obtain evidence of the relation of the supposed contestants in the spleen, liver, and marrow, the organs in which regressive and progressive blood changes are constantly going on. I have not myself practised puncture of the spleen in these cases, as has been done extensively by Councilman. Fatal cases of malaria are not now very common. I have only had opportunities of examining two, both of chronic paludal cachexia, the result of prolonged exposure in Panama. One, an old man, admitted under my colleague, Dr. Musser, whose blood presented many of the characteristic forms; the other, a profoundly anæmic man, with a greatly enlarged spleen, but in whose blood very few of the parasites were found. In both instances the liver, spleen, and bone marrow showed charrcteristic melanotic changes. In the spleen the pigment in various shades, from brown to deep black, was chiefly in the thickened trabecular tissues and about the vessels. Teased portions showed:

(1) Large numbers of leucocytes containing brownish-black pigment grains. A few of the leucocytes contained the small amœboid forms which had been noticed to be very abundant during life.

(2) Larger cells, containing red blood-corpuscles in all stages of degeneration. These cells were of various sizes, and contained a variable number of corpuscles, from eight to ten, or even more. Some of the red corpuscles contained amœboid parasites, but by far the larger portion of them presented the usual appearance met with in cells of this character in the spleen.

(3) Large, irregular, flattened cells, probably derived from the epithelium of the spleen capillaries, which contained granular black pigment, and occasionally red blood-corpuscles.

(4) Spindle or branch cells of the reticular tissue enclosing brownish or black pigment grains.

(5) Free pigment.

Practically the condition was similar, though more extensive in degree, to that met with in this organ and in other febrile states associated with extensive blood destruction. I really could not say that the splenic phagocytes exercised any selective power in picking out for attack those corpuscles which contained parasites or crescentic forms, which in one of these cases existed in considerable numbers. The bone marrow in both cases presented microscopic changes characteristic of the lymphoid tissue, and had a grayish-brown color, due to excess of pigment. There were in it in large numbers marrow cells and ordinary leucocytes containing irregular pigment, and occasionally free amœboid forms of the parasites. The cells containing red blood-corpuscles were very abundant, but here, as in the spleen, it was particularly noted that the red corpuscles not containing the parasites were as frequently, or even more frequently, enclosed in the cells. In the liver the pigment existed in three elements.

(1) In leucocytes, which seemed numerous in the lobular capillaries, particularly at the periphery.

(2) In the walls of the capillaries, in all probability in the endothelial cells.

(3) In the stroma cells, particularly of the interlobular tissue about the portal canals, where in places it was sufficiently abundant to cause ordinary diffuse pigmentation, a part of which was due to grains lying free in the interstices of the tissue.

Metschnikoff states that in malaria the parasites are attacked chiefly in the spleen and the liver by the larger phagocytes existing in these organs, and to a much less extent by the leucocytes in the circulating blood.

We see, then, in malaria very little evidence in the blood favoring a theory of phagocytosis; certainly no such campaigning on the part of the leucocytes as might

be expected from the presence, in such numbers, of foes so destructive to the red corpuscles. In the spleen, bone marrow, and liver, the organs in which the dead or dying blood-disks are normally cremated, to use Weigert's expression, we have, as might be expected, an activity proportionate to the increased amount of material to be consumed, but scarcely such heightened phagocytic action as would indicate, on the part of the leucocytes, an aggressive warfare.

Into the interesting theory that to the action of phagocytes is due the immunity against certain diseases or against a second attack, I cannot now enter. In the present unsettled state of our knowledge it would be premature.

To conclude: While phagocytosis is a widespread and important physiological process throughout the animal kingdom, and while it undoubtedly plays a most important part in many pathological conditions, the question of an active destructive warfare waged by the body cells against the microörganisms of disease must still be considered an open one.

THE EFFICACY OF FILTERS AND OTHER MEANS EMPLOYED TO PURIFY DRINKING-WATER.

A Bacteriological Study.[1]

By CHARLES G. CURRIER, M.D.,
of New York.

Water, even after having been exposed to various chances of contamination, is very generally drunk as it is received from lakes or rivers, wells or springs, tanks or hydrants; and, despite the most disinterested warnings, people are not ready enough to believe that clear, sparkling water may at times be the most harmful of beverages; that it can carry with it, and introduce into the systems of a portion at least of those who drink it, the immediate causes of various impairments of health. Polluted water may be agreeable to the taste and have no visible sediment, yet cause many deaths. Such water the unskilled are slow to suspect, and but for the advance in sanitary science and the warnings conveyed by those familiar with hygienic studies, pure supplies of drinking-water in cities would be much more of a rarity than they are.

At the Hygienic Congress in Vienna, in 1887, M. Brouardel stated that he knew of over sixty epidemics of typhoid fever which had been induced by the drinking of infected water.[2] From typhoid fever thousands of deaths occur every year; and, although scientific physicians are constantly urging these facts, it seems to be necessary that the danger present itself in the form of an epidemic before the people fully realize the immense harm which may result from impure drinking water. The epidemic which ravaged Plymouth,[1] in Pennsylvania, four years ago, attracted great attention at the time, but the history of several similar "visitations" since then would indicate that the full value of this severe lesson has not been properly appreciated.

Water may be very highly colored, and yet, if freshly collected near its source, show no very large number of bacteria. Such is the case with the best of the peaty "juniper" water which I have examined in various parts of the Dismal Swamp of Carolina and Virginia. Although having a large proportion of organic matter, this water is reputed eminently wholesome, and an inquiry among a portion of those drinking this exclusively, appears to show an unusual degree of immunity from the manifestations of diseases which might be attributed to the effects of improper drinking-water.[2] On the other hand, the turbidity which is common at this season of the year in the streams furnishing the water supply of many of our cities, is almost always accompanied by a large number of bacteria, as in these bottles of water which you see here from the Mississippi and from some of the rivers flowing into the Atlantic. The melting snow and the rain, which wash into the streams an increased amount of organic matter, introduce with it other germs (perhaps pernicious), and bring more nutriment than usual to the microorganisms already in the water, thus increasing their vitality and numbers.

It is believed that, like most of the varieties of bacteria found in water, the still larger forms of animal and vegetable life, ordinarily existing in lakes and rivers, are not prejudicial to health. It is through the products of the decomposition of many of these, when their life has ceased, that they may become harmful.

Chemistry has long furnished a means of recognizing polluted water, even when it yielded no sediment visible to the unaided eye, and the presence of considerable quantities of chlorides, nitrites, and

[1] Read before the Section on Public Health of the New York Academy of Medicine, April 5, 1889.

[2] Dr. A. Ollivier: Rapport au Conseil d'Hygiène Publique (etc.), Paris, 26 mars, 1886. A valuable monograph on typhoid fever by a scientific practitioner. As different parts of Paris receive water from rivers of very different quality, the careful health reports from garrisons and institutions, which vary only in the purity of the water supplied, are very instructive.

From the abundant evidence as to the influence of polluted water in inducing typhoid, may be cited the report of the Zurich Water Commission of 1885.

[1] Biggs and Breneman: N. Y. Med. Journal, vol. xli. (1885), May 23 and June 6. French and Shakespeare: ibid., June 13. L. H. Taylor: The Medical News, vol. xlvi. (1885), May 16 and June 20.

[2] If harmful bacteria be introduced into it, such water favors their increase, while they would not be so apt to multiply in a very pure water having much less organic matter. Despite the good reputation which this water has had, and its wholesomeness near Lake Drummond, one who has seen the whole length of the canal down to the lower end, from which the supply for vessels is taken, can realize that the water may undergo considerable contamination before it reaches that part. I am sure that the present use (in our navy) of distilled water, kept in proper receptacles, is safer than the employment of the swamp water.

ammonias, determined by the chemical tests, has shown that many a water had more organic impurity than was permissible; and, when far below the accepted standard in this respect, such a water is very justly condemned. Yet it seems as though enough of the infective element of cholera or typhoid to diffuse an epidemic throughout a community can be added to a drinking-water and not be detectable by chemical tests. A perusal of the very complete and instructive paper by Professor J. W. Mallet (in the report of the National Board of Health for 1882) shows how widely such determinations may vary and how unreliable chemical standards may be.

The known disease-producing bacteria, however, do not appear to increase in water[1] in which there is not more organic matter than the proportion that chemists of constant and large experience regard as permissible in waters which they pronounce to be of fair quality, although these harmful bacteria, if once introduced there, may long retain their vitality and remain dangerous.[2]

Since, as yet, chemistry, when called upon to aid in solving the question of the purity of a water, can at its best only approximately estimate the amount of organic matter present and its state of oxidation, while it fails to inform us whether infective matter be present or not in a given water, it has been hoped that a sure means of recognizing whether a water be in any degree infected was reached when Koch introduced the bacteriological test. This test, while very definite and conclusive under favorable conditions, has thus far been able to decide absolutely in only a small portion of the cases of disease apparently coming from the use of drinking-water. Yet in those cases where the bacteria characteristic of distinct disease have been detected in the suspected water, the isolation, culture, and identification of the disease-producing species furnish a convincing proof of the great value of the method.

The method employed is a simple one. Usually one cubic centimetre of the water to be tested is added to ten cubic centimetres of nutrient jelly, made by solidifying very nutritious beef-tea by the incorporation of one-tenth its weight of gelatine. Everything being done with rigid precautions, the water to be tested is added to the nutrient jelly, which has been softened by being warmed to a little more than 30° Centigrade. This is then quickly mixed and poured upon a cooled glass plate, where the fluidified gelatine soon becomes quite solid. Then the germs in the water, being scattered evenly throughout the mass, exercise their functions of rapidly multiplying at the room temperature; and, in the nutritious medium, the minute microscopic individual has perhaps by the third day become a dot as large as a pin-point, or much larger, containing thousands or millions of newly formed bacteria. These are called "colonies," and vary considerably in appearance, as will be seen by comparing the plates made with various waters. With a glass ruled into centimetre squares the number can be counted or estimated. If a large number of thousands be present, as in waters artificially prepared for tests and in sewage contamination of water, the only way to arrive at an accurate estimate is to employ in the eye-piece of a microscope a micrometer square, as first used, I believe, by Dr. Edw. K. Dunham, who combines with it the aid of an automatic counter. After determining the number we isolate and identify the species as in general bacteriological study.

There are many features of the subject which must be omitted in a paper of this scope, for they may not interest all, while the limits of the usual time allowed must be respected; and as the important points are to be discussed by eminent experts, I will not linger over the still unsettled question as to the absolute value of mere numbers of ordinary water bacteria in determining the sanitary merits of a water.[1] It is, however, admitted that the fewer the varieties present, the less is the likelihood of sources of contamination affecting the water. In examining a considerable number of samples of water from various sources, I have observed that the less chance of contamination there was, the fewer bacteria have I found in the waters. Thus, fine mountain lakes and springs have never in my experience, unless

[1] In my tests, when I prepared an artificial water, I added the germs directly from a pure culture, unlike Bolton, and like Wolffhügel and Riedel (Arb. aus d. Gesundheitsamte, 1886, i. p. 455), with whose results, however, I cannot so well agree as I can with those of Bolton (Ztsch. f. Hygiene, 1886, i. p. 76). I have in but two out of many trials, with disease-producing species, found typhoid bacilli to increase in sterile pure water, and then only to the extent of thirty per cent.

[2] Chantemesse and Vidal (Gaz. Hebdomadaire de Méd. et de Chir., 1887, pp. 146–150) kept typhoid bacilli alive for "months" in sterilized water from the Ourcq, which is the worst water supplied to Paris, and much impurer than the Croton, in which, when it was sterilized, I have been able to keep typhoid bacilli alive for only two weeks, and usually not over eight or nine days. I have observed that the greater the variation of temperature it was exposed to, the shorter time did this microörganism live in water. It has been found by all observers that oscillations of temperature around the freezing point were much more destructive to these than freezing them in water and allowing the ice to remain frozen. So, I have observed several times that of two flasks of the same typhoid water, the one which was kept at a temperature varying from 37° C. to 10° C., had, at the end of three days, many fewer than were in the flask kept between 16° C. and 10° C. In my last test of this sort, the flask of which the temperature varied most had, after two days, only a few more than a third of those in the one kept at the evener temperature. under very unfavorable conditions, shown as many as one hundred bacteria in each c. c., while the same quantity of water from a river draining thickly peopled valleys may show more than fifty times as many. While it offers less striking extreme differences than I have seen in the Hudson Valley and elsewhere, the Passaic water-shed may be briefly instanced as illustrating what I have just said. I give it because it is the smallest one near us offering every phase of importance in this connection, and because the subject of a supply to come to New York from that source has been seriously considered. The best of the upper lakes of this system showed on a pleasant day of the past winter only fifty-seven germs developing in the nutrient gelatine, while the Pequannock and other tributaries into which these lakes flow showed, in the samples collected as nearly at the same time as possible, over three hundred and fifty germs, which number increased as the water was taken further down stream; while at the Passaic Falls, in Paterson, over a thousand were detected in each c. c. Water from the hydrant in Newark, at the same time, showed nearly four thousand germs of bacteria in each c. c. The Newark water supply is at present derived from the Passaic, some miles below the place where sewage from Paterson is discharged into the river.

As in chemical, so in bacteriological water examinations, those who have had the broadest experience and who are most careful are best in a position to pronounce an opinion. Apart from any personal equation, there are still limitations to the entire comprehensiveness of the method. I may mention that bacteria are recognized as present in the human body and in its products and changed tissues, which bacteria are never found to live on the gelatine or other water plates. Then, too, a water may be submitted for examination when all the obvious infection has disappeared, or has become exceedingly diluted, and hence a most painstaking test then fails to reveal the presence of the characteristic microorganism. The period of incubation, after the infection and before the symptoms are recognized, may in Asiatic cholera occupy the greater part of a week, and in typhoid often lasts for two weeks or more, so that all traces of the harmful bacteria may have left the water before it is suspected. By reason, also, of its likeness to various harmless species, and its tendency to be overwhelmed by other more rapidly developing forms, the "colony" of the disease-producing species may be hard to identify. In this respect typhoid is decidedly more difficult than cholera to recognize in ordinary water.

For those who believe that bacteria of certain kinds living in water, and with this introduced into the alimentary canal, can in many cases induce disease, this test, being so precise and delicate as it is, must appear the best way of determining whether the filters and other means in common use are efficient or otherwise in removing the dangerous elements from impure water passed through them—in short, whether they act as "disinfectants" of the water.

As various other agencies are used in conjunction with, or as supplementary to, filtration, it is proper that I here indicate how far they serve to purify drinking-water. One of the most prevalent means directly resorted to for this ostensible purpose is the admixture of wine (usually red). Adding this to an equal amount of Croton water, I find that a varying proportion of the bacteria are killed, sometimes less than half, even after the mixture has stood for days. The spirituous alcoholic beverages (having from 45 to 68 per cent. of alcohol), mixed with Croton hydrant water in equal parts, cannot be depended upon to kill all of the bacteria, especially when "earth" bacteria are present, and a small percentage of whiskey (less than 20 per cent.) has very little effect in this direction.[1] In malt liquors, as lager beer, the prolonged boiling in the brewer's kettle has destroyed the bacteria of the original water, even if they be of the most harmful and resistive species which we meet here. Various kinds, however, if present in vats, kegs, and bottles (because of imperfect cleansing), will live in beer.[2] Almost all the artificial mineral waters that I have examined are made of unsterilized water. Pressure of carbonic acid gas, and contact with it for days, reduces greatly the number of bacteria in a mineral water, yet the typhoid bacillus and others will live for days in Seltzer water. In New York I have found many bacteria in the few carbonated beverages that I have examined.

Of the various acids which it is occasionally safe to employ, chemically pure hydrochloric acid must be used in the strength of at least one-half of one per cent. to destroy all the germs in Croton water to which *B. subtilis*, *B. typhoid*, and other bacteria have been added; and may fail to sterilize the water even after hours of standing thus acidulated. Sulphuric acid is more than twice as potent, and usually in the strength of one part to five hundred of water

[1] Koch (Flügge, Chapter V., sec. 3) found that the spores of *Bacillus anthracis* were alive even after months of exposure to the action of absolute alcohol.

Pasteur and Joubert (*Comptes Rendus des Séances de l'Académie des Sciences*, 9 and 16 juillet, 1877) stated long ago that the spores of anthrax would remain alive in absolute alcohol.

Anthrax, however, need not be expected to occur in the water supplied here, and several recent experiments show that it is possibly destroyed by other bacteria which may occur in the water.

Anthrax spores are employed in such tests because they are considered the most resistant of all disease-producing forms of bacteria.

[2] The bacteria from this source which I have found in examining a limited number of beers were mostly of non-liquefying kinds, and there were notably many iridescent "spreading" colonies. [Jan. 1889.]

In these cases water from old surface wells was used to wash out the kegs.

will render this free from living germs. Sometimes, however, it has to be used still stronger, as it is in a certain extensively advertised nostrum, in which, under a fanciful name, it plays the principal part. Alum, lime, and the other chemicals which, by inducing sedimentation of organic and mineral constituents, carry down many of the bacteria in water, do not (as is often believed) insure the annihilation and destruction of organisms present.[1] It is the mechanical action of the film, which the presence of a minute amount of these causes to settle sooner than would otherwise occur upon sand in certain large sand filters, which insures their excellence, and the scarcity of bacteria must here not be attributed to a coarse chemical action. When chemicals are added in sufficient strength to destroy speedily all the bacteria which may be present, the water thus treated cannot be recommended as a beverage.

With the imperfection of all other methods, we have in prolonged boiling a sure disinfectant of any water. I have usually found that maintaining a water at the boiling point for even less than fifteen minutes sufficed to prevent any of its germs from developing in gelatine, and this even with bad waters[2] from sewage-infected rivers. The process of distillation likewise sterilizes water.

That freezing temperatures destroy only a certain proportion of the bacteria which exist in the water from which the ice we use is formed, must, I think, be evident to those who have read Dr. Prudden's masterly paper on this subject. He there shows that the typhoid bacillus in ice retained its vitality for one hundred and three days. As he will discuss the subject this evening, I shall simply echo his previous warning against putting ordinary ice into water which we are to drink, as many kinds of bacteria may be thereby introduced.[1]

The mechanical separation of impurities is the principal action in all filters, whatever their composition. The amount of oxidation produced by the passage of considerable quantities of water through inconsiderable masses of charcoal, sand, or anything else, seems never sufficient to chemically purify an infected water, although the Berlin system of filtration, by large beds of sand skilfully managed, effects a notable improvement in this respect.

Almost all tissues tend to separate visible particles from water which is turbid, or in which a deposit settles. The fact that such matter is retained from the water passed through filters appeals very strongly to most persons; and the general assumption that such visible matter is dangerous, and that its removal insures the purification of water, seems to explain the extensive use of filters. They are all composed of felt-like matter (filtrum), or of any tissue or substance so woven, composed, or arranged as by its structure to more or less completely arrest the passage of sediment and the floating particles existing in varying amounts in nearly all natural waters. The filters in domestic use may be ranged in two classes. In one class the water runs or is poured into a tank or other receiver over or beside some filtering medium, through which the flow is into a receptacle, and from this the water is taken as needed, or is stored as fit for drinking. Those of the second variety are designed to connect with the faucets, and to strain from the water such impurities as it brings through the hydrant.

One of the most widely used varieties is this simple

[1] Residents of the Mississippi Valley, where the principle of settling water by adding alum has been extensively made use of, have expressed to me their belief that many digestive irregularities are caused by the use of alum. The danger lies in the use of an excess, and probably does not exist with the small amount which is permissible (2 : 100,000).

As was just noted of absolute alcohol, Koch also found that the spores of the *B. anthracis* were not destroyed by prolonged exposure to the action of a four per cent. solution of alum (or a concentrated solution of chloride of lime).

[2] The employment of silk threads, in and upon which are dried living bacteria with spores, seems to endow these germs with greater resistance to the action of steam heat than when the bacteria are (as in drinking-water) each surrounded by water. Having tested various waters from different cities, I was lead to believe that heating for a very short time sufficed to sterilize them. So I have made several series of experiments on the spore-bacteria usually regarded as most resistant. I used Croton water, sterilized and not sterilized, and bacteria from pure cultures on agar and potato (where the spores were, just before the experiments, seen by the microscope to be very abundant). I added from these cultures a small amount to water in flasks. These flasks were well agitated several times; then several plates made to test the presence of living bacteria. The water was from these poured into sterile tubes and Erlenmeyer flasks plugged with cotton. Several of these were tested before and after the heating. A wire basket, holding eight of these cool test-tubes or flasks (each having from ten to twenty c. c. of the infected water), was placed in a heated steam-box. The temperature ranged from 93° upward, but the thermometer did not register above 100° C. These tubes were taken out as rapidly as I could cool the plates at once prepared from them (at intervals of from three to four minutes). While this is not so absolute as are some other methods, it seemed the best for the practical object aimed at. In this way I found that the spores of *B. anthracis* failed to develop on gelatine (in five days) after they had been boiled in clear water for from two to five minutes. That this result was not extraordinary will appear to those who consult a remark by R. Koch (and Gaffky and Löffler) in Mittheilungen aus dem Gesundheitsamte (1881), p. 322.

My results with *B. subtilis* are likewise not in accordance with the accepted views. I am still experimenting in this direction, but have never found any water bacteria (which would develop in nutrient gelatine) after the water in which it was had been boiled for even a tenth of the time (six hours) which Globig states as necessary to kill (by steaming) the most resistant red-potato bacillus with which he experimented (Globig; Ztschr. f. Hygiene, iii., 2, p. 231). He used silk thread wrapped in filter paper.

[1] Prudden; on Bacteria in Ice, etc., N. Y. Med. Record, March 26 and April 2, 1887.

Bordoni-Uffreduzzi (Centralbl. f. Bakt. u. Parasitenkunde, i., 2 Band (1887), p. 495) insists that in natural (Italian) ice the bacteria which survive the extensive destruction caused by the cold of freezing do not gradually decrease, but that they indefinitely retain their vitality. He states that he agrees with Dr. Prudden's results in that disease-producing forms of bacteria resist freezing better than the harmless ones.

Fränkel—Bakt. des Eises—Zeitschrift f. Hygiene, i., 2, p. 302.

and portable one, which renders water clearer and more agreeable to the eye. It is composed of a cylinder of pressed carbon, three inches or less in diameter, and having nearly the same depth, which has from its interior a tube passing through the bottom of the funnel in which it rests, and thus requiring all the water passing out of the bottom of the funnel first to go through the mass of carbon. The flow is very sluggish unless use be made of pressure or suction, as, for example, by lengthening the tube taking water out of the filter, which impairs the effectiveness of this so far as purification of the water is concerned. After this has been used for a few days the retardation is very marked, and is due to the clogging of the filter by the various matters which form the sediment of the unfiltered water. This necessitates frequent cleansing.

Taking a freshly sterilized carbon filter of this sort and pouring into the funnel Croton water just drawn after considerable has run from the faucet, and then collecting in sterilized test-tubes the first flow from the filter, adding of this (as already explained) one cubic centimetre to ten parts of softened nutrient gelatine, the mingled gelatine and water being poured upon a cool plate, it is seen that, before three days have passed, several colonies have developed. Comparing the number of these with that found from the original Croton water plated just after being drawn, we find that at least from five to eight per cent. of the bacteria pass through the filter and develop. The percentage rises as more and more water flows through. From fourteen trials made with simple Croton water, I found that through a carbon filter, freshly sterilized and the introduction of germs from the air and other sources of contamination being guarded against, the first flow showed only a small percentage of the bacteria found in the original water used. Then I continued the use of the same filter without resterilizing, and endeavored in every way to have the conditions under which it was tested as much as possible like those which would exist in domestic use, and the supply of water in the funnel was allowed to become exhausted at times, as usually during the night.

In this filter thus used, the number of bacteria in the water passing through is, on the second day and thereafter, much larger than in the water taken after being poured into the funnel and before it has percolated through the carbon block. This excess, when large, seems to bear an inverse ratio to the volume of the flow.

It is a familiar fact that, if fresh hydrant water in a flask covered with cotton (to prevent the entrance of bacteria from the air) be allowed to stand for a day at the temperature of the laboratory, the original bacteria in the water may be found to have increased considerably. So, as a collateral test, after water had been poured into the filter and before it had passed through the carbon, I have taken some of this original water and allowed it to stand in test-tubes and flasks, both stoppered and open, by the side of the filter similarly protected from the entrance of germs from the air, and exposed to the same variations of temperature.

This water, examined at the same time with that coming out of the filter, showed that the bacteria appear to multiply much more rapidly in the substance of the filter than outside in separate flasks, likewise kept at the varying temperature of the laboratory, as it then was. The water poured in rarely contained as many as 225 bacteria in each c.c., and yet in from one to three days from the time when the freshly sterilized filter had begun to be used, the water after passing through the carbon showed several thousand in every case, and at times more than 25,000 bacteria in each c.c.

All sorts of bacteria appeared to pass through, and not alone water species. The bacillus of typhoid fever will not only pass through, but in two of my trials I found that it had increased. For such special tests I used sterilized Croton water, into which bacteria[1] were introduced from pure cultures. For artificial typhoid-water the bacillus of typhoid was added from agar and potato cultures. Harmful bacteria can pass through such filters, can possibly increase in them under certain favoring conditions, and from parallel tests seem to retain their vitality longer when in the substance of the filter than when in a glass vessel beside it.

Clean sand fairly represents the granular masses of filtering material, and has all the advantages of powdered charcoal and magnesia as generally used for filtering considerable quantities of water, while it is more readily cleansed of the accumulated organic matter and, unlike spongy iron,[2] adds nothing objectionable. Unless, as in the case of the large Berlin filters and others acting similarly, rendered more effective by overlying silt and organic matter, beds of sand do not prevent the passage of large numbers of bacteria. I have found many bacteria in waters from various artesian wells coming from a deep stratum of sand. Through a thin sterilized

[1] B. fluorescens (Oneida) and B. liquef. alb. aq. (Croton). For cocci: Staph. pyog. aureus and a coccus obtained from the water of Salmon River, west of the Adirondacks. For a spiral form: Sp. tyrogenum was used as being harmless, yet similar to the cholera microörganism.

[2] For some of the reasons why spongy iron has fallen into disuse, especially in America, see a very instructive paper by the late Prof. W. R. Nichols in the Ninth Report of the Massachusetts Board of Health, 1878, p. 137.

For favorable notice of spongy iron, see Frankland, Proc. of the Royal Soc., No. 338, 1885. I do not care to consider it here, for it is a proprietary preparation as offered upon the market (in London), is variable in quality, and never sold here.

layer, from six inches to one foot in depth, of the finest sand procurable from beaches, all the way from forty per cent. to ninety-five per cent. of the bacteria in the original water pass, even when the level of the water is never more than three inches above the surface of the filtering mass. When a higher pressure is afforded by the water, very few of the bacteria are kept back.

As in nearly all other filters, so through a layer of sand all kinds of bacteria, harmless or harmful, appear to pass easily. Here, too, they can multiply in the moist sand. Thus, I have found the hydrant water, which entered the sand filter with 290 bacteria in each c.c., to come out through the filter (not freshly sterilized before using) with sixty and one hundred times as many as entered. In a gramme of sand taken from a filtering bed, I have found more than 10,000 bacteria.

The combination of other substances with sand, as in numerous small and large filters, fails to improve the usefulness of either, except in so far as the elimination of sedimental and other coarser particles is concerned.

Sponge is often employed for this purpose, as well as independently, yet it is incapable of separating bacteria from the water strained through it simply, or through sand or other substances used with it. When a large mass of fine, sterilized sponge is closely packed, the first few ounces of hydrant water that pass through may have a very small percentage of bacteria, but the proportion soon increases, while if the sponge-mass be considerable and loosely packed it may, even in the beginning and under exceedingly slight pressure of water, keep back no more than fifteen per cent. of the bacteria of the original water. This freshly sterilized sponge can at the end of the first day of ordinary use cause the water then flowing through it to contain from increase ten times as many bacteria as the Croton water poured in. The stronger the pressure, and the more rapid the flow, the lower is the ratio of excess due to increase in the filter over the quantity found in the unfiltered supply, which, of course, was here, as in all other tests, regularly plated at the same time with the filtered water. When the flow is sluggish, and when it stops entirely at times because of all the water supplied having passed through, the sponge substance favors the increase of the bacteria to a greater extent than is the case with sand. The sponge, within twenty-four hours after sterilization may, under these conditions, cause the water first running through after the intermitting of the flow to have five hundred times as many bacteria in each cubic centimetre as are found in the water supplied for filtration.

The only way really to cleanse such a filter is to remove the sponge and boil it. Then the process repeats itself. In a few hours after unsterilized water moistens it, the mass of sponge is again teeming with bacteria. Sponge filters are, so far as I have seen, becoming less popular. It is easily recognized, even by an untrained observer, that the organic matter in sponge can undergo decomposition under the conditions obtaining in ordinary filters. Several of the large filter systems used in manufactories, hotels, and other places where large amounts of strained water are used, employ sponge and the filtered water abounds in bacteria.

Filter paper, as used in laboratories, is useful in separating precipitates and sedimental particles from water, but at least from fifty to seventy per cent. of the bacteria in Croton hydrant water go through with the water filtered, even if the pressure be exceedingly slight. The paper which I employed in the trials was, of course, carefully selected, and the folding was cautiously done, so as to prevent any break in the substance. Only single sheets were tested.

"Prepared cotton," cleansed as for surgical dressings, and so made absorbent, removes considerably fewer of the impurities of the water than does the filter paper. Two-thirds of the bacteria pass through when the cotton is at its best, freshly sterilized and carefully packed. If enough be used, it will usually render the water clear; but, as it has been lauded as a filter, I ought to add the statement of my observation that, when left moistened with water, as in the intervals of filtering through it, the bacteria of the original water can multiply over one hundred and fifty times, and all kinds can pass through it.

Combinations of the various substances mentioned have hardly any enhanced merit as strainers, and, as far as the bacteria are concerned, the combination seems to add no safeguard. Sand with carbon (bone charcoal) and sponge or cotton, hold back at first a larger percentage than sand would, by itself. Yet bacteria pass through in any case, and the increase afterward is greater than in simple sand. This I have seen in various filters.

In a well-known bottling establishment of New York, where immense quantities of artificial waters are prepared every week, all the water used in their preparation flows through a layer of fine sand in the bottom of an enormous vat and, from the receptacle into which it then flows, it passes through a layer of charcoal. These layers are each less than a foot in thickness, and water passes rapidly through. The sediment is thereby removed, but in the single examination which I was enabled to make I found that each cubic centimetre of the filtered water had over 3200 bacteria on each of the two plates made, while the Croton taken from the hydrant in the immediate neighborhood on the day before averaged a few over one-eighth as many (432).

Asbestos of the best quality, new, freshly sterilized and tightly packed, I have found capable of

holding back all bacteria when the pressure of the water was low, and the few that were forced through when the substance was defective did not seem to multiply so rapidly as in other filter-masses. While it, when of the best finish and most tightly compressed, deserves to rank next to the principle employed in porcelain filters, these latter are superior in that they can be regularly furnished of a uniform and definite quality which produces the best results, while I have found it difficult to keep the best asbestos boards up to their original standard of excellence, and if the surface be large enough to insure an abundant flow of water, flaws are liable to arise, and these let various bacteria through. With asbestos it is the fineness of the surface which the original water encounters that is important more than the thickness of the layer.[1]

Although wire cloth strains out the coarser particles, its structure does not cause the removal of any of the bacteria from water passing through. Still it has the positive merit of being easily cleaned, and can be heated in an oven or boiled to sterilize it. Furthermore, it does not furnish a filter-mass for the bacteria to multiply in, although harmful bacteria can adhere to it and become dangerous if it be left uncleaned.

Closely woven cloth, such as thick, dense flannel, when only a slight pressure is exerted by the water, may stop ten per cent. of the bacteria in the water poured upon it. It is easily cleansed and, if very often changed, and boiled before using, it serves excellently as a simple strainer without the disadvantage, in this respect, of ordinary filters, in whose substance the increase of bacteria may be enormous.

Like porcelain, filters of porous stone, if of the best quality, prevent the passage of bacteria with the water filtered through them just after they have been sterilized. To test porous stone I employed selected perfect specimens of a popular filter which very satisfactorily clears all turbidity from as bad a water as that of the Hudson River at its worst. In these, the stone layer was cemented into a porcelain cylinder and was about three-eighths of an inch in thickness. The pressure was never more than that of ten or eleven inches of water, and, at the fastest, less than three-fourths of a litre passed through in an hour. As the sediment of the water settled upon the surface of the stone, the flow became much slower. During twenty-six trials of this kind of filter, it had previously been sterilized ten times by exposure to moist or dry heat, or to both, for several hours. In every one of these ten cases the various waters poured into the receptacle above the porous stone for the first time after sterilization, flowed through germ-free; that is, the stone was permeable for water, but at first allowed no bacteria to pass through, and the plates of gelatine developed not a single colony from the usual cubic centimetre of the filtered water. After some hours of use, a few bacteria had insinuated themselves into the stone or were drawn through with the water. Within twenty-four hours the water flowing through and collected in sterilized receptacles contained many bacteria, which numbered regularly from seven to fourteen times as many as were in the original hydrant water supplied during these trials. After several days, the number of bacteria had so multiplied in the stone, that the first water running through after the stone had remained for several hours without any flow through it (as happens constantly over-night in domestic use), showed in each cubic centimetre of this filtered water over one hundred times as many as the average water poured in for filtration. To test further these filters, I have used artificial waters made by adding bacteria of all shapes and characters, from pure cultures to Croton water sterilized by boiling. These various kinds can get through, but the disease-producing and spiral forms usually died out in large numbers before any could pass. From Croton water, the most marked by its predominance in the filtered product was a short, mobile bacillus which was unlike the two varieties first forced through the porcelain in my experiments.

(To be concluded.)

SUCCESSFUL CASE OF NEPHRORRHAPHY FOR FLOATING KIDNEY.[1]

By W. W. KEEN, M.D.,
PROFESSOR OF SURGERY IN THE WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA.

Miss E. J. F., of Sunbury, Pa., aged thirty-five, height four feet eleven inches, weight ninety-two pounds, was sent to the Woman's Hospital on October 4, 1888, by Dr. Mary A. McCay, with a diagnosis of floating kidney. For the following notes I am indebted to Drs. Chapin and McKee, resident physicians. The patient was delicate as a child; menstruation began at fifteen, and was always painful and irregular. At eighteen years of age she was thrown from a wagon, falling with considerable force on her chest and abdomen. Shortly after the fall she suffered from severe pain in the right side and a great deal of distress across the back. Menstruation ceased for six months, and was followed by dropsy and severe illness. There was frequent inclination to vomit, and a great deal of palpitation of the heart. In spite of constant medical attention, she dragged out a miserable existence. About seven years after the fall she noticed a movable tumor in the abdomen, which Dr. McCay believed to be a floating kidney.

Condition on admission.—Appetite and sleep poor; urine 1020 sp. gr., slightly alkaline, twenty-nine

[1] Read before the Philadelphia County Medical Society, March 27, 1889.

ounces in twenty-four hours, no albumin, no sugar. Heart and lungs normal; uterus retroflexed. In the right abdomen was a tumor, about the size of the kidney, which could be freely and easily pushed two or three inches to the left of the middle line back into the right lumbar region, or down into the right iliac fossa. Neither the hilum nor the bloodvessels could be distinctly made out. Percussion over the position of the right kidney showed a tympanitic note, the left renal dulness being distinct and normal. The tumor was evidently not connected with the uterus, ovary, or liver.

Operation, October 26, 1888.—Ether was administered. An oblique incision was made at the outer border of the quadratus lumborum four inches long. So soon as the abdominal fat was discovered, search was made for the kidney. The colon was first found, but the kidney was absent from its normal position. Strong pressure being made on the abdominal tumor, it was partly pushed back into position, but could even then only be touched by the finger-tip. On separating the borders of the incision by retractors, it was seen to be the kidney, bare of all fat. In order to replace it entirely, it had to be seized by a volsella. Seven carbolized silk sutures were next introduced by a Hagedorn needle, four posteriorly and three anteriorly, through the capsule and substance of the kidney, by which it was attached to the muscles and aponeurosis of the abdominal wall. Seven deep sutures of chromicized catgut were then introduced through the entire muscular wall of the loin, but they were not tied, as I intended that the wound should remain open for a few days, if not permanently, in order to produce cicatricial tissue between the kidney and the muscular wall. No provision for drain was necessary of course. The wound was covered with an ample bichloride gauze dressing. Her recovery was entirely uneventful. Her highest temperature was 100.9°. The urine was entirely free from any blood, though the bladder was irritable, and the catheter had to be used for several days. The wound was so completely filled up within the first forty-eight hours, that I removed the stitches that had been passed through the muscular wall. I kept her flat on her back for four weeks, when she was allowed to rise for a short time. There was considerable, apparently rheumatic, pain in the small of the back for three or four weeks after the operation, which disappeared and again reappeared, and which seemed to be benefited by salol. Seven weeks after the operation there was a moderate amount of albumin in the urine, which disappeared after the use of Basham's mixture for three weeks. Soon after she got out of bed, I tried the effect of a pad to support the kidney in front, but its use caused so much discomfort that I abandoned it, trusting wholly to the silk sutures and cicatricial tissue to hold the kidney in place. The tumor formerly discovered in the abdomen was entirely gone, and the normal renal dulness reëstablished, though a little lower down. She went home on the 5th of January, 1889. I heard from her to-day, March 16, 1889, and she says: "My back is still weak, but the pain is fast disappearing. The kidney is still firmly anchored, and I am feeling better generally. Words cannot express my gratitude to you for what you have done for me."

REMARKS. *The cause.*—A lax abdomen following frequent pregnancies has been supposed to be the origin of floating kidney, as it is of floating liver. In the case here narrated the patient was unmarried, and the abdominal wall was not at all lax. Again, the absorption of the perinephritic fat has also been supposed to be a cause; but in this case, as soon as the abdominal wall was penetrated, the perinephritic fat was at once encountered. But it was a noticeable fact that the kidney itself was entirely free from any fat. In other words, the fatty bed in which the kidney should lie was in its proper place, but the kidney was displaced, and there was no fat on the kidney itself. It seems reasonable to conclude that the dislocation of the kidney was due to the fall at the age of eighteen, though the abdominal tumor was not discovered till seven years later. Landau, who has written the best monograph both upon floating kidney and floating liver, states that, of 314 cases of floating kidney, 273 were in women as against 41 in men. In 178 cases, it existed on the right side in 151, on the left in 13, and in 14 on both sides. The present case being in a woman, and upon the right side, emphasizes still further his statistics.

The symptoms.—Digestive disturbances, especially constipation and very fetid breath, were not marked, though they were present to a moderate degree. The chief trouble was pain and constant discomfort, which was not only physical, but mental, the very existence of the tumor being a source of constant worry. The tumor itself was not especially tender to the touch, but it created a constant aching pain. Neither the hilum nor the pulsating renal artery could be distinctly made out, but the character of the tumor and the altered renal dulness made the diagnosis quite clear.

The treatment.—Recumbency alone has been advised by Landau, but this seems to me altogether too expectant. Only the most sanguine could believe that by this treatment, if such it can be called, a kidney would resume its normal position and quietly continue there sufficiently long for the adhesions to be reëstablished with any prospect of permanency.

I did not try any treatment by pad or bandage, as the patient was from a distance and could not remain the long time necessary to decide whether such palliative treatment would answer. On the other hand, extirpation of the organ was equally foreign from my thoughts. In my opinion, this should only be done after failure of an attempt at fixation. The danger to life of a floating kidney is absolutely *nil*. It is, therefore, only to remedy the discomfort that exists that we operate. Hence, I

do not think extirpation at all justifiable unless we first attempt to fix it *in situ*, and having so failed, it is only justifiable even then in case the discomfort is very great. Dr. Maurice H. Richardson (*Boston Med. and Surg. Journ.*, June 14, 1888), who has published an excellent paper with a full bibliography, quotes from Brodeur the following figures: Of 235 nephrectomies, 125 were done by lumbar incision, with 47 deaths (37.6 per cent.), 110 by abdominal incision, with 55 deaths (50 per cent.). As against this large mortality from nephrectomy, however, Gross has collected 17 cases of nephrorrhaphy, with only 1 death, a mortality of only 6 per cent. It should be added also, that in the fatal case (Ceccherelli, *Centralbl. für Chir.*, 1884, 44, 743) the surgeon passed the stitches around the twelfth rib, a procedure which is absolutely needless as well as dangerous.

Hahn (*Centralbl. f. Chir.*, 1881, p. 449) first proposed fixation for a floating kidney by operative procedure, and practically perfected the operation. The operation is simple. The patient being laid upon the side, an oblique incision is made at the outer border of the quadratus lumborum. The edge of this muscle being recognized, the perinephritic fat is found immediately in front of it, at its outer border. This fat having been cut or torn through, the kidney may be seen at once, but, if it is very movable, it may be so far displaced as not to be seen, or, as in the present case, may be even felt with difficulty by the tip of the finger, even when an assistant pressed it firmly back through the abdominal wall.

Mr. H. Morris (*Surgical Diseases of the Kidney*, p. 45) makes a distinction between a kidney which has no mesonephron but moves freely about behind the peritoneum, this being called a "movable kidney," and a "floating kidney" which does possess a mesonephron, and therefore floats freely in the peritoneal cavity. In cases, therefore, of a strictly floating kidney, it would be necessary to open the peritoneal cavity before it could be fixed in the loin. This distinction is confirmed by four cases of dissection to which Mr. Morris refers. Comparing them with the present one, the range of movement to the left of the umbilicus and into the right iliac fossa was so great in this case, that it would seem proper to call it a "floating kidney," yet, at the operation, no renal mesentery or mesonephron was found. The probable mode of its production would also militate against the existence of any mesonephron. The kidney was far away from its normal position, but when pushed back into its proper place no layer of the peritoneum could be found that by any possibility could be called a mesonephron, and the peritoneum was certainly not opened.

In spite of the fact that Paoli (*Centralbl. f. Chir.*, 1885, 51, 910) cut through the twelfth rib in order to obtain room, it would seem to be rarely necessary to do so. When found and pressed back, the kidney should be fixed as nearly as possible in its normal position. Usually it will be impossible to replace it as high as it was at first, but lowering the site by two inches is not uncommon, and seems to be of no importance.

The sutures that have been employed (either of silk or of catgut, disinfected, of course) may be passed (1) through the capsule of the kidney, or (2) through the parenchyma and capsule both, and may either be (3) left permanently or (4) removed. In this case I employed antiseptic silk, which I consider decidedly the best, and passed the stitches not only through the capsule, but through the parenchyma of the organ itself, three on the anterior surface and four on the posterior, stitching the kidney to the muscles, and what I consider more important, to the aponeurosis, which exists on each side of the incision. Finally, these stitches were not removed, but were left *in situ*. I believe with Svennson (*Centralbl. f. Chir.*, 1886, 824), that many failures have been due to employing absorbable catgut, to the avoidance of passing the stitches through the substance of the kidney, and to removal of the stitches, which in all cases I think should be left in, whatever the material employed. Svennson inserted as many as fourteen silk stitches, which were left in place and caused no trouble. The wound is best left to heal by granulation. I introduced a number of stitches to close the abdominal wall if necessary, but in twenty-four hours it was so filled up that it was evidently a needless precaution. The larger amount of cicatricial tissue that is produced by leaving the wound to heal by granulation probably fixes the kidney more firmly.

Another very important point is, that the patient lie flat on the back for at least a month after the operation, in order that the cicatricial tissue binding it in place may become thoroughly developed and firmly established. Even then, I would advise some support for the kidney in front by a pad or bandage, provided the patient bears it well. In this case I soon abandoned it, as it caused too much discomfort. It is to be noticed that though the stitches were passed through the kidney substance, the patient had no hematuria (this was carefully watched for) and that no inflammation or reaction seemed to follow. But seven weeks after the operation considerable pain developed in the region of the kidney together with some albuminuria. This disappeared, however, after the use of Basham's mixture. The pain seemed to be rheumatic, and was soon relieved by the administration of salol.

LOBULAR EMBOLIC PNEUMONIA.[1]

BY THOMAS E. SATTERTHWAITE, M.D.,
PROFESSOR OF PATHOLOGY AND GENERAL MEDICINE IN THE NEW YORK POST-GRADUATE SCHOOL AND HOSPITAL.

(Concluded from page 404.)

EMBOLIC pneumonia is usually bilateral; when single, the right and left lungs are attacked with equal frequency, in my experience, though in that of others the right lung is most often affected.

There is reason to suppose that embolic pneumonia may occur at any age of life, though in my eighteen cases I have only noted it between the age of fourteen and sixty-eight. In pyæmia it may, of course, occur at any period. In cardiac cases it is most apt to occur in middle life, presumably when cardiac compensation is breaking down, or when the system is beginning to show the signs of age. Among the antecedent diseases, or phenomena, were noted the following:

In eight cases endocarditis.

In eight, pyæmia, either from some fall, mechanical injury, or from operative procedures.

In three, pericarditis.

In three, chronic Bright's disease.

In one, chronic bronchitis.

Some of the conditions occurred jointly in one individual. The cardiac cases were mostly associated with mitral disease; the pyæmia with surgical operations on the pelvic viscera in the male sex.

In approaching the topic of symptomatology we are at once confronted by the fact that we have to do with a disease that exhibits few characteristic traits at the bedside; and that we are often debarred from an inquiry as to them, either by the coincident systemic disease, whose other manifestations are of vastly more importance; or because the patient is unable to submit to a physical examination, without which a diagnosis would be conjectural. Hence, embolic pneumonia has not only been an obscure topic clinically, but is likely to remain so for some considerable time. More than this, embolic cardiac pneumonia usually occurs in patients that are already suffering from the interstitial pneumonia of heart disease, with a considerable amount of bronchial catarrh, and often pulmonary œdema to some extent; so that an infarction would naturally be more or less masked. Add to this, that infarcts occur chiefly where respiration is very feeble, and we have an additional difficulty thrown in our way. Indeed, we have not a single pathognomonic symptom. Take, for example, the temperature. The rise is slight, or there may be none at all. Even in pyæmic cases we may not be able to tell whether a sudden rise is due to the pneumonia, or to some other more distant manifestation of the disease. In cardiac affections there will be little or no rise of temperature when infarction occurs; when the infarct has been recognized as a foreign body, we have reason to suppose that fever will show itself. Sometimes in a cardiac case the temperature will be subnormal. If it rise, it will not pass 102°; 101¼° is the highest I have known.

In reference to physical signs I have found that they were marked in *only* about fifty per cent. of my cases. In two, the regular signs were present, but there was little in the others on which to fix a diagnosis. In two, there were the signs of pleurisy only. In two prolonged expiration, in one of which there was vocal fremitus, in the other cough. In one there were "whistling or squeaking" sounds, supposed to be due to obstruction. In one there was fine crepitation, with mucous râles. Of course, if the area of consolidation is large there will be no difficulty in getting physical signs, especially as the infarctions are apt to be peripheral. Pain in the side was present in only three instances and colored sputum in two. The pulse rate is rarely high. I have found it as high as 120, but it is rarely above 100. The respiration will usually be hurried. It is most so in pyæmia and may reach 30 to 50 and even 60. In cardiac cases it is not so much increased. If the infarctions reach the pulmonary pleura, which is usual, there will be pleurisy. Hence this secondary affection may be looked for as a regular phenomenon, and it will facilitate the diagnosis, unless there is much effusion.

It will be apparent, therefore, that we should not base our diagnosis on any symptom or group of symptoms, but should take them all into consideration. Signs of uræmia should not be neglected. I found them present in exactly half my cases.

The causes of death I found as follows:

In 10 septic poisoning.

In 3 heart failure.

In 1 cerebral compression.

In 1 cerebral embolism.

In 1 exhaustion from diarrhœa.

In 2 the causes were indeterminate, though in 1 of these the patient had uræmia.

The prognosis varies according as the case is cardiac or pyæmic. In the cardiac variety we have reason to suppose that the process *tends* to ultimate resolution with recovery. In examining an infarcted lung that has shown the signs of protracted heart disease, there is always evidence to show that restoration is being accomplished; in fact, our clinical experience sustains this view, but a fatal issue may take place at any time, though the cause of death is not directly traceable to the respiratory tract. Usually the disease will last a long time, and indeed like the broncho-pneumonia of children and of adults, it is characterized by successive inroads upon the lung. It is, therefore, subacute in its course. In pyæmia

the result will be fatal in almost every instance, perhaps in all. It is bound to terminate in pulmonary abscess, if the patient survive the early stages of the disease. From such suppurations there can be no recovery, I fancy.

Our treatment of embolic pneumonia is usually unsatisfactory. Jürgensen in his famous monograph refused to discuss it.[1]

But dismissing from our consideration the topic of pyæmic pneumonia, which obviously needs no discussion here, and taking up the cardiac form of the affection, it is plain that we do have a condition of the lung that will often appear before us for treatment, and which we shall have to care for.

It is true that the cardiac disease first enlists our attention, with its attendant dangers, heart failure, cerebral embolism, and possibly septic poisoning.

And hence we very properly direct our main efforts toward securing strength and rhythm for the heart's action, while we enjoin upon our patient the necessity for his observing a proper dietetic regimen, and seek to impress on him the necessity for regulating his manner of life so as to avoid all heart strain. Naturally, too, we seek to correct any constitutional vice that may lie at the root of his cardiac trouble.

And the success that attends these efforts of the intelligent practitioner will often cause the disappearance of the pulmonary complication, or check its occurrence. Hence treatment is important though it be indirect. But if the lung has been implicated to any great extent, the direct treatment that is applicable to areas of extensive consolidation finds here an appropriate field.

In the vast majority of cases the prognosis of embolic pneumonia in heart disease depends upon the nature of the primary cardiac disease. The pneumonia of itself seldom kills—though it may, by a hemorrhage.

In fact, an embolic pneumonic process of itself actually tends toward spontaneous resolution.

The following cases are instances of the disease:

CASE I.[2]—A gentleman of this city was taken sick with a fever that confined him to his room for four or five days; then feeling better he went down stairs but soon returned and took to his bed. During the first two weeks of his attack the temperature ranged from 98° to 100°; the pulse from 140 to 150, sometimes to 160. It was manifest that he was suffering from aortic stenosis. But the respiration was never embarrassed except when the patient sat up; there was no pain except over the spleen. After death the post-mortem examination revealed infarctions in the lungs, spleen, and kidneys, and suppurative foci were found in the meshes of the pia mater. This case was classed as one of the so-called infective or suppurative endocarditis. The cusps of the aortic valve were covered with vegetations. The pulmonary symptoms were masked by those of the other viscera.

CASE II. (Case No. 12 in Table.)—A widow, twenty-eight years of age, entered the Presbyterian Hospital in December of 1877. She expressed herself as having been delicate for five years, having had a slight cough all the time. But for seven years she had suffered from her heart and eight years previously had experienced an attack of acute rheumatism. About three weeks before admission she was taken with a chill. Breathing was found to be short and rapid. Expectoration frothy, pulse 120. Temperature 101¼. Nausea, pain in the right side—no heart murmurs, but heart's action feeble. The urine contained albumin in large quantity. The patient died apparently of exhaustion. At the post-mortem examination it was found that there was a marked mitral stenosis of an extreme character, the orifice being button-hole-shaped and only ¾ inch in its longest diameter. The kidneys showed evidences of a slight degree of chronic diffuse nephritis. The liver was of the nutmeg variety. In both lungs there were nodules of embolic pneumonia; in the right one the size of a turkey's egg, with some smaller ones. Left lobe in a similar condition.

CASE III. (Case No. 9 of Table.)—This is an example of pyæmic or embolic pneumonia leading eventually to an abscess. M., a salesman, was admitted into St. Luke's Hospital in December of 1882, for stricture of the urethra near the meatus. It was a stricture of large calibre and was easily cut with Otis's dilating urethrotome. In the evening some little difficulty was experienced in passing a flexible catheter, and water to the amount of only fifty ounces was drawn. Ten minutes afterward the patient had a chill, on the following day the patient had a second chill after the catheter was used. The temperature had now arisen to 101° and there was delirium with convulsive twitchings of eyes and hands, but these bad symptoms ameliorated and the patient talked intelligently; on the following day he died cyanotic. At the post-mortem examination infarctions from the size of a pea to a marble were found in the left lung, with a small abscess in the lower lobe. In the middle lobe of the right lung were several small collections of pus. The patient had also chronic diffuse nephritis.

[1] Jürgensen in Ziemssen's Cyclop., vol. v. p. 259.

[2] This case is not included in the Table on page 435.

MEDICAL PROGRESS.

The Clinical Significance of Colorless Stools Unaccompanied by Jaundice.—DR. ANDREW CLARK, at the meeting of the Royal Medical and Chirurgical Society of London, held March 26, 1889, read a paper written by Dr. T. J. Walker upon this subject. After referring to the accepted views of the significance of clay-colored stools, the author gave particulars of two cases in which, during life, a persistent symptom was the absence of color in the feces, and in which the diagnosis made of obstruction of the pancreatic duct, with a healthy condition of the bile-duct, was confirmed by the necropsy. From these cases Dr. Walker concluded, first, that the formation of hydrobilirubin, the coloring matter of the feces, depended on the mutual reaction of the bile and pancreatic fluid, under

the influences met with in the intestinal tract; secondly, that in disease a deficiency of pancreatic fluid would, equally with a deficiency of bile, cause the pathological condition of colorless or clay-colored stools; thirdly, that since, according to the most recent physiological researches, that portion only of the colored constituents of the bile which had been converted into hydrobilirubin was excreted in the feces, while the unchanged bilirubin, bilifuscin, and biliverdin were absorbed, it followed that, if hydrobilirubin could not be produced without the aid of the pancreas, that organ must have an important *rôle* in regulating what proportion of the bile entering the intestines should be absorbed and what thrown off in the feces.

Dr. Walker then pointed out that these conclusions received confirmation from the records of other published cases, that Claude Bernard recognized that the pancreas had a part in causing the color of the feces, and that the state in which the bile pigments were found in the meconium of the fœtus, while the pancreatic function was in abeyance, also accorded with these conclusions. He further pointed out that the fact of the pancreas influencing the excretion of the bile in the feces would, if accepted, reconcile the discrepancy between the clinical observation that certain drugs produced copious bilious stools, and the physiological observation that these drugs had little or no influence on the secretion of bile by the liver, and that the same fact would explain those hitherto inexplicable cases in which, with no evidence of arrest of the bile-secreting functions of the liver, or of obstruction of its ducts, the symptom of white or clay-colored stools was persistently present. In conclusion, Dr. Walker indicated the practical importance of the views he had endeavored to establish in the treatment and diagnosis of pancreatic disease and of all forms of bilious disorder.—*British Med. Journal*, March 30, 1889.

The Treatment of the Navel of the Newborn.—Dr. A. Baginsky, at a meeting of the Society for Internal Medicine, of Berlin, stated that he had seen no good results follow the application of moist antiseptic bandages to the navel of the newborn, as recently recommended and practised by a number of gynecologists. He considers the application of carbolic acid as most dangerous, for only a small abrasion of the navel is necessary to cause toxic symptoms which generally terminate fatally. He himself uses as a bandage, cotton to which small quantities of iodoform have been applied.

The Treatment of Phimosis.—The treatment of phimosis was also discussed on this occasion. Two varieties of this affection exist. In one variety we have to do with a short, rigid prepuce with internal agglutination. Simple cutting without dilatation is the best treatment for these cases. In the second variety we have to deal with a very long prepuce, and frequently with suppression of the secretion, swelling, and the discharging of pus. For these cases Dr. Baginsky advises dividing the prepuce. In a case of pyæmia which came under the author's observation, the fatal termination could only be attributed to the obstinate refusal on the part of the patient to submit to an operation, thus giving the microörganism every opportunity to invest the body and to set up, in the various organs and extremities, necrosis and suppuration.—*Wiener med. Presse*, March 17, 1889.

Creasote in the Treatment of Tuberculosis.—Dr. Bourget, of Geneva, gives in detail the treatment of tuberculosis with creasote, as first described in the *Semaine Médicale*, No. 10, and as at present carried out at the Medical Clinic of Geneva. The object of this method is to saturate thoroughly the organism with creasote. To accomplish this, creasote is given internally, externally, and by means of inhalations. In winter, creasote is given internally with cod-liver oil, as follows:

℞.—Cod-liver oil . . . . 500 parts.
Creasote . . . 2 to 4 " —M.

From two to three tablespoonfuls to be taken daily.

In summer, when cod-liver oil is not well supported, creasote is given in the following formula:

℞.—Creasote . . . 30 to 45 grains.
Arseniate of sodium . ¾ grain.
Malaga wine . . . 1½ pints.—M.

Two wineglassfuls daily at mealtime.

Besides this, inunctions are made every evening with the following ointment:

℞.—Creasote . . . . . 10 parts.
Lanolin, Lard, Olive oil . . . . āā 50 " —M.

Make an ointment.

Finally, the patient wears day and night a permanent inhalation-apparatus, consisting of two small pipes, one for each nostril, through the centres of which runs tissue paper saturated with creasote.—*Wiener med. Presse*, March 17, 1889.

Therapeutics of Bisulphide of Carbon.—Some observations on the employment of bisulphide of carbon, made chiefly in the Purisima Hospital, Santiago, S. A., are published in the *Revista Médica de Chile*, and show that this unpleasant remedy may have more therapeutic power than it is usually credited with. It has occasionally been employed in this country for diarrhœa, and externally for ulcers. Sapelier also employed it with apparent advantage in typhoid fever, and it has been recommended in diphtheria and other diseases in which microörganisms occur. The Chilian cases referred to included one of acute and one of chronic dysentery, one of atonic dyspepsia, one of simple gastric ulcer, and one of typhoid fever. The dose given was generally about two ounces of a saturated solution of the bisulphide in water, mixed with half a tumblerful of milk or a little syrup, taken half an hour or so before meals. This very quickly relieved the pain and tenesmus. In the typhoid case, which occurred in a child of ten (not a hospital patient), whose condition was becoming alarming, enemas of a pint of water, containing about half a drachm of bisulphide of carbon, were given, in addition to the internal administration of iodide of potassium and kairin. The diarrhœa diminished, the stools rapidly lost their offensive character, the gurgling disappeared from the iliac region, and the patient made a good recovery.—*Lancet*, March 23, 1889.

Operative Treatment of Prolapse of the Rectum.—Dr. J. Mikulicz, of Königsberg, describes in the *Archiv für klin. Chirurgie*, vol. xxxviii., his method of dealing with

prolapsed rectum, and puts on record seven cases in proof of its safety and efficacy. Of prolapse of the rectum there are, it is pointed out, three forms. The first and simplest of these, prolapsus ani, is a mere ectropium of the mucous membrane of the rectum in which the other coats of the gut, especially the muscularis, are seldom involved. In the second form, that of true prolapsus recti, the protrusion consists of all the coats of the intestine and, like the invaginated portion in intussusception, presents on section two tubes of intestine one within the other, and in contact by their serous surfaces. The third form, to which the name is given of prolapsus coli invaginati, is really intussusception of some part of the colon, and may be readily distinguished from the other forms by the fact that the external layer is not fixed to the anus, and that the finger can be passed into the rectum by the side of the protruded mass.

In cases of chronic prolapsus recti, with ulceration and gangrene of the exposed mucous membrane, and a persistent tendency to further protrusion, excision of the protruded portion of the intestine is, according to Mikulicz, the most suitable treatment. The limited excisions devised by Dieffenbach and Dupuytren are, it is stated, often useless and do not guard against prolapse, and cauterization, though a milder proceeding, is still not free from risk and may cause stenosis of the anal portion of the gut. Partial excision and cauterization will, it is true, result in contraction of the relaxed and softened sphincter, and of the immediately superjacent portion of rectum, and the constricted and rigid extremity of the gut will, if the case be a mild one, resist further protrusion from above; but in too many instances the *vis a tergo* overcomes this resistance and the cicatricial tissue yields sooner or later to renewed prolapse of the rectum. It is necessary, he states, to shorten the elongated and displaced rectum, and, in correspondence with this indication, to resect a large portion of the prolapse. This is held to be the most rational course in all old cases of prolapsus recti, and particularly after relapse.

The operation described in this paper was first performed with success by Nicoladoni, and resembles in some respects one advocated by Esmarch, in which, before resection, the upper part of the prolapsed gut is fixed tightly by ligature to a bougie introduced into the rectum so as to prevent any exposure of the peritoneal cavity. Mikulicz, after having passed two sutures through the free lower end of the prolapse, in order to stretch and fix in required positions the gut, makes a transverse incision through the anterior layer of the prolapsed mass, about half an inch below the anal margin. The inner tube of the prolapse having been thus exposed, the serous margins of the outer and inner layers are brought together by sutures, in order to shut off the peritoneal cavity. The inner tube having been divided transversely along the whole length of the outer incision and the intestinal canal opened, the cut edges of the inner and outer tubes are then fixed together by a second row of sutures. The posterior surfaces of the tubes are then divided and sutured in like manner, and the whole of the prolapse thus detached. In most cases the peritoneal sac does not descend between the layers of gut behind, the space being usually occupied by mesocolon which contains numerous vessels. In this operation Mikulicz insists on the use of silk in preference to catgut for the material of the sutures.—*Lond. Med. Recorder* March, 20, 1889.

Tait's Operation for Ruptured Perineum in Russia.—In the *Meditzinskoïe Obozrenïe*, No. 16, 1888, p. 287, Dr. Vladimïr v. Üspensky, of Moscow, published ten cases of perineoplasty for partial perineal rupture, in which he performed Lawson Tait's operation slightly modified by himself and Professor Snegïreff. The modification consists in (*a*) the formation of a regular elongated quadrangular wound by making a semilunar or curved, instead of a straight, transverse incision into the remnants of the perineum; and (*b*) in inserting sutures through the skin instead of through the raw surface, at some distance from the cutaneous edge. In no case was there more than a trifling amount of bleeding. The operation, including the insertion of sutures, only occupied from five to twelve minutes. The sutures were removed between the eleventh and fourteenth day, when the wound was invariably found healed by first intention. The results left nothing to be desired. A solid and generally perfect perineal body was obtained in every one of the cases. Dr. Üspensky emphatically declares that Lawson Tait's method is the best in every respect, its advantages being extreme simplicity, rapidity of performance, and uniformly excellent practical results. He believes that it will supersede all other perineoplastic operations, at least in cases where no special indications are present, such as excessive tenderness of scars, demanding excision, etc. The same opinion was expressed by Professor v. F. Snegïreff at a meeting of the Moscow Obstetrical and Gynecological Society.—*British Med. Journal*, March 30, 1889.

Treatment of Jaundice from Retention.—Dr. Le Gendre gives in the *Concours Méd.* the following treatment for this affection:

1. *Absolute milk diet*, consisting of five pints of milk taken pure or in an alkaline medium, in quantities of eight ounces every two hours.

2. *Intestinale antisepsies*, for which the following powders are to be taken:

℞.—β Naphthol (finely powdered) . 23 grains.
Salicylate of bismuth . . . 15 " —M.

Divide into ten powders; one to be taken every time that some milk is taken.

3. *Sponging the body* every morning and evening with cold water, to which the following has been added:

℞.—β Naphthol . . . . 1 part.
Water . . . . . 5000 parts.

Heat and dissolve, filter and allow to cool.

4. *Purgatives* of a sodic base (such as sulphate of soda, etc.), to be taken every third day.

5. *Inhalations of oxygen*, or air-baths, if circumstances permit.

Although insomnia is often a troublesome symptom in this affection, it is best not to give any hypnotics, especially not morphine. Sleeping can frequently be induced by calming the troublesome itching with the following lotion:

℞.—Sublimate } āā 5 grains.
Chlorhydrate of ammonium }
Camphorated alcohol . . ℥j.
Cherry-laurel water . . . ℥ixss.—M.

—*Revue de Thérapeutique*, March 15, 1889.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,
PER ANNUM, IN ADVANCE . . . . . $5.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, APRIL 20, 1889.

THE DIURETIC ACTION OF CALOMEL.

ALTHOUGH the medical profession is wont to hold itself as being a little better in respect to general knowledge, at least in the line of its own labors, than many other occupations, it is worthy of remark that almost any one can gain notoriety in its ranks at the present day, simply by turning over the pages of long-forgotten medical lore, and from them resurrecting some remedy, which in the hands of our ancestors often worked for good; particularly is this true if he be so conscienceless as to claim it as his own discovery.

While the diuretic action of calomel is not perhaps an instance of this kind, the practical lesson to be learned is the same. Calomel as a diuretic was one of the most frequently used of drugs for dropsy by Dr. J. K. Mitchell many years ago, and was also a standard remedy in the teachings of Dr. George B. Wood, yet at the present time clinical and experimental studies without number are published upon the subject, as if calomel was as new as erythrophlein. In a manner closely allied to this, Bergeon's treatment of phthisis arose, although our grandfathers for years used sulphur and sulphur waters in the treatment of such respiratory ailments.

Turning aside from the historical to the clinical facts, which, after all, must attract our attention, we find that at present the mass of modern evidence is so greatly in favor of the value of calomel as a diuretic that it cannot be denied by the most conservative. The researches of JENDRÁSSIK (*Arch. für klin. Med.*, Bd. 38, 1885, p. 499), of Wolf (*Virchow-Hirsch Jahresbericht für* 1887), and an innumerable number of others, have all reached results which, as a general rule, are singularly given to praise.

In the *Centralblatt für die gesammte Therapie*, for February, 1889, PAL, of Vienna, gives us still another report of a favorable character. Like many of his predecessors in this field, he has simply used calomel in cardiac dropsy, or more rarely in renal dropsy, and in the accumulation of fluid which results from cirrhosis of the liver. The results obtained by him are given in tabular form with the reports of the cases, and are as follows: In case number one, the man, who was twenty years of age, had a history of rheumatism in early life followed by cardiac disease which manifested itself in the course of about one year. Later he became confined to bed and was somewhat improved for a short time in his general condition by the use of digitalis. Finally, pain in the region of the liver, cardiac palpitation, dyspnœa, and anorexia asserted themselves, and a physical examination showed an icterode conjunctiva, a marbled skin, slight œdema of the feet and a double mitral murmur. The liver and spleen were both enlarged. Digitalis again acted favorably, but, nevertheless, calomel was soon added, opium being given to prevent intestinal overaction. As Pal's table shows with great clearness, the use of the mercury increased the urinary flow every time it was given, and also that the stoppage of the calomel, leaving digitalis to act alone, decreased the urinary flow to one-half or one-third that caused by calomel. Considering the increased quantity of liquid given off, the specific gravity remained fairly high, pointing to the presence of an increased amount of solids. Along with these changes there was marked general improvement.

The second case is illustrative of the fact that this calomel treatment is of very much less value in those cases in which there is degeneration of the heart muscle and cardiac infiltration. The patient was a man of forty-seven years, in whom cardiac palpitation, dyspnœa, and swelling of the feet with icterus was present, associated with loud murmurs at the apex and aortic cartilage, and who had an enlarged spleen and liver and albuminous urine. Calomel was used with little result. The man died and at the autopsy there was found aortic insufficiency and dilatation of the right heart. There was also universal dropsy and bilateral hydrothorax with chronic

endarteritis and occlusion of the coronary arteries. It is useless for us to go on detailing the states of the patients treated by Pal by calomel. Those who are especially interested should go to the original paper for further details. Suffice it for us to state that he gives us a profusion of tables showing, perhaps, even more forcibly than we have done, that the mild chloride of mercury is a powerful diuretic. Thus, in one instance in which the quantity of urine was only 800 c.c. in the twenty-four hours under the influence of the acetate of potash, calomel in small doses increased it in the course of four days up to 10,700 cubic centimetres, there being simultaneously a decrease and disappearance of the albuminuria which had been present.

Studies such as these are worthy of record and careful reading, as well as trial, and we are only sorry that more evidence of how calomel acts under these circumstances is not forthcoming. It is to be remembered, of course, that whenever any sign of intestinal disturbance is produced by the mercury opium should be used, although in any event the quantity of calomel given should be below that which is capable of causing ptyalism.

DR. SAMUEL W. GROSS.

THE death of Dr. Gross, on the 16th inst., leaves a sad blank in the profession of Philadelphia, and is a grievous loss to American surgical science, of which, as his father before him, he was a distinguished ornament. To be thus struck down in the prime of life, in the midst of his work, and so full of zeal and energy, accentuates the shock of his death and deepens the sense of our bereavement.

He well maintained the strong reputation of his name, and every year brought him increasing fame as a thinker and writer in surgery. Carefully prepared, judicial, and systematic, his contributions were of solid worth and will have an enduring place in our literature.

As a teacher Dr. Gross had reached an enviable position, and his didactic and clinical lectures were models of clearness and precision. Of him, as of his father, it may be written, he taught principles—no slight merit in these days of devotion to technique.

Physically well endowed, there were in his nature exceptional qualities of mind and heart—a genial *bonhomie* and frankness and a warm, hospitable disposition which made his home the natural rendezvous of strangers in Philadelphia—qualities which now leave mourning an exceptionally wide circle of friends in this country and abroad.

To his family and colleagues we extend our warmest sympathies in their affliction. In our next issue we shall give a full notice of his life and work.

MEDICAL EDUCATION OF WOMEN.

FOR some years McGill University, Montreal, has had a well-equipped Arts Department for the education of women, and not a few ladies have succeeded in taking the degree of B.A. The women now ask that the Medical Faculty admit them to their classes and are stirring up their friends to bring this about. The Medical Faculty object to mixed classes, and although not very enthusiastic on the subject, hint that a very large endowment ($400,000 to $500,000) might induce them to consider the subject of separate education. The ladies interested are busily engaged in collecting an amount of money for this purpose, and so far have been fairly successful. Public meetings have been held to promote the scheme, and the press is strongly in favor of "giving the ladies a chance." There are already two colleges in Canada for the medical education of women, viz., one in Toronto, and one in Kingston, Ont., and many medical men think these are quite capable of supplying the immediate needs of the country.

A PRELIMINARY programme of the General Sessions of the American Medical Association, Newport meeting, has just been issued. The President, Dr. W. W. Dawson, of Cincinnati, will deliver the Presidential Address, on the first day, Tuesday, June 25. The Address on Medicine, by Dr. William Pepper, of Philadelphia, will be delivered on Wednesday; the Address on Surgery, by Dr. P. S. Conner, of Cincinnati, on Thursday; and the Address on State Medicine, by Dr. W. H. Welch, of Baltimore, on Friday.

THE Shelby County, Indiana, Medical Society held a most successful anniversary meeting at Shelbyville, on April 8th. It was largely attended, and there were present several prominent medical men from a distance.

THE Third Congress of the German Society of Gynecology will be held at Freiburg, June 12 to 14, 1889, at the Woman's Clinic of the Grand-Ducal University. The following are the subjects for discussion: Autoinfection; referee, Dr. R. Kalten-

bach, co-referee, Dr. H. Fehling. Treatment of Extra-uterine Pregnancy; referee, Dr. Werth, co-referee, Dr. G. Winter. In addition a number of valuable papers will be read.

An International Congress of Otology and Laryngology will be held at Paris from the 16th to the 21st of September, in the palace of the Trocadéro. Professor Duplay is President of the Committee of Organization, but all communications should be addressed to the Secretary, Dr. Loewenberg, Rue Auber, 15, Paris.

A considerable number of English and American physicians having accepted the idea of a Continental Anglo-American Medical Society, a meeting was held in Paris on March 14, 1889, at which the following gentlemen were present: Drs. Barnard, Boggs, Bull, Chapman, Darcus, E. Dupuy, Faure-Miller, Hon. A. Herbert, Jennings, Linn, Loughnan, Murray, Nachtel, Warren-Bey, and Webb. In addition to the above Paris practitioners, about forty from other places on the Continent have written to express their approval of the project, and many more are expected to send in their adhesions. At this meeting it was resolved to form a society under the above title, limited to British and American physicians residing abroad, the first general meeting to take place in Paris, on Monday, September 30, 1889, to be followed, in the evening, by a public dinner.

An Executive Committee was appointed to study the scope of the Society, to draw up articles of Association and By-Laws, and to submit suggestions, all to be voted upon at the first general meeting in September.

It was further decided to invite a certain number of distinguished members of the profession to become *Honorary Presidents* of the Society. The following names were proposed: Sir Spencer Wells, Sir Joseph Lister, and Dr. Richard Quain, for England; Drs. Fordyce Barker, Weir Mitchell, and J. S. Billings, for America, and Professors Ball and Brown-Séquard for Paris.

The following gentlemen compose the Executive Committee: Drs. Hon. Alan Herbert, Faure-Miller, Chapman, E. Dupuy, Barnard, and Linn, the last named being the Secretary.

At the semi-annual conversational meeting of the Pathological Society of Philadelphia, to be held next Thursday evening, 25th inst., Prof. Roswell Park, of Buffalo, will read a paper entitled "A Study of Acute Infectious Processes in Bone."

We regret to learn that Dr. R. C. Word, of Atlanta, editor of the *Southern Medical Record*, lost, by a disastrous fire on March 16th, his home and its contents, including his lecture notes and the MS. of a work nearly ready for the press, together with other valuable papers, the accumulation of years. We are sure that we are echoing the feelings of his colleagues of the medical press in expressing the warmest sympathy for Dr. Word in his great loss.

Mrs. Turner Sargent, daughter of Dr. Oliver Wendell Holmes, has bequeathed $5000 to the Massachusetts General Hospital, $25,000 to Harvard College for the general purposes of the University, and the further sum of $10,000 as a memorial of her father, the income to be applied to the use of the anatomical department, under the direction of the professor of anatomy. In the event of her brother, Judge Holmes, leaving no issue, she further bequeaths $25,000 to the Boston Medical Library Association.

George Tiemann & Co., of New York, have just published *The American Armamentarium Chirurgicum*, a handsomely printed quarto volume of 862 pages, being a descriptive illustrated catalogue of surgical instruments and appliances, with a brief account of their uses and prices. The book must prove extremely valuable to the practising surgeon. It can be obtained, we are informed, upon the payment of a small sum, about covering the cost of binding.

SOCIETY PROCEEDINGS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, March 27, 1889.

The President, W. W. Keen, M.D., in the Chair.

Dr. L. W. Steinbach reported the following

CASE OF NEPHRECTOMY.

July 17, 1888, Mrs. Anna H., forty-four years old, came to the Polyclinic, complaining of indigestion, frequent vomiting of food or of mucus, attacks of palpitation of the heart, and loss of flesh. One week before attention was directed to an induration in the right hypochondriac region.

She considered herself in good health until eleven years ago, when she became dyspeptic. Five years ago she noticed a lump in her abdomen, and until one month ago she was able to attend to her household duties. She complained of headaches and constipation, and had not

noticed any sediment in or discoloration of the urine, nor could she recall having suffered with pain that would indicate the passage of a biliary or renal calculus. Pulse, respiration, and temperature normal, looked anæmic, complexion muddy, body emaciated. Inspection showed a prominence in the right lumbar region, whilst percussion and palpation revealed the presence of a tumor extending from the lower border of the ribs vertically for about seven inches, and, laterally, occupying the centre of the lumbar region to the extent of three inches. Percussion dulness was continuous with that of the right lobe of the liver. The tumor was freely movable below, and felt through the thin abdominal walls imparted the sensation of a bag filled with small pebbles. Believing that the case was one of a gall-bladder filled with calculi, and fearing lest manipulation would cause rupture of the cyst, he desisted from further palpation, and directed inquiries toward finding other symptoms of biliary obstruction. He drew off the urine with a catheter and submitted it to a chemical analysis, which showed the absence of albumin and the presence of some bile-pigment. No particulars of the nature of the stools could be obtained. He recommended a cholecystotomy.

On July 26th, an incision three inches in length was made in the right linea semilunaris, over the most prominent portion of the tumor, beginning at the border of the ribs and dividing the abdominal muscles and peritoneum; the apex of the tumor was reached without encountering any of the abdominal viscera. The calculi could now be felt more distinctly; an incision was made, and a few pieces of calculus removed, which, however, did not correspond in shape, color, and general appearance to calculi of biliary origin, and the forceps grasped a stone evidently of large size and immovably fixed.

The idea of impacted gallstones was dispelled—the tumor was a kidney.

Fear of rupturing the normal gall-bladder vanished, the lips of the abdominal incision were drawn apart more freely, and brought to view the margin of the right lobe of the liver and a normal gall-bladder in normal position. Further examination showed the tumor to be the right kidney distended by several calculi of different shapes and sizes. The organ was twisted by being turned upon its vertical axis from behind forward and to the left, and upon its horizontal axis from above downward and from behind forward, so that the dorsal surface and the upper end presented at the anterior abdominal wall.

It was at once decided to remove the kidney, a superficial examination indicating the existence of a kidney on the left side. The pedicle, consisting of ureter, artery, and vein, was ligated *en masse* with a silk cord, the kidney cut off, the abdominal incision closed with sutures and dressed. The patient, after half an hour, came from under the influence of the anæsthetic. Three hours after the operation the bladder was catheterized, but no urine obtained. Catheterization was repeated at intervals of six hours during the two succeeding days with a like result. The temperature at 8 o'clock P.M., six hours after the operation, was 101° F., falling to 99° on the following morning, gradually rising to 103° toward evening, and falling in the same manner to 100° on the morning of July 28th. She slept for a few hours during the night after the operation, and after a small dose of morphia was given without his knowledge, took moderate amounts of nourishment and some stimulants. About noon of the third day began to complain of soreness all over the body, became irritable and restless, but continued to take milk and whiskey. She passed no urine up to the time of her death, which occurred at 6.20 P.M., fifty-four hours after the operation. A post-mortem examination was not held.

DR. J. H. GROVE then presented the specimens from

A CASE OF MALIGNANT TUMOR INVOLVING THE KIDNEY AND SUPRA-RENAL CAPSULE.

The appearance of the tumor indicated that it sprang from the supra-renal capsule; extended to and involved the left kidney, and that the supra-renal capsule was the seat and origin of a large cyst which was filled with grumous fluid and fatty disintegrated *débris*.

DR. W. W. KEEN then reported

A CASE OF NEPHRORRHAPHY

(see page 431),

and also a case of

UNCOMPLETED NEPHRECTOMY.

G. M. C., aged sixty-eight years. On April 6, 1886, had an attack of retention of urine. Violent expulsive efforts forced out a clot. The bleeding continued two or three days. With this he had pain in the right lumbar region. A month later another similar attack occurred, amounting to a distinct renal colic. Other attacks occurred in July, 1886, and in January, September, and November, 1887. After the last one, for several weeks he had repeated and nearly continuous hematuria with a sensation of heat in the right lumbar region, and he lost strength and appetite. January 14, 1888, he was taken extremely ill with pleuro-pneumonia and septicæmia. Both legs were attacked with phlegmasia. The dulness in the right kidney was increased, but no pus was found in the urine either then or at any other time; neither were any symptoms located in the bladder. This illness lasted about two months.

In May and June of 1888 he again had attacks of hematuria, and from September 17 to October 31, 1888, he has had nine attacks, passing as much as six or eight ounces of blood, he thinks, in some of the attacks. He has never passed any calculus. In the interval between the attacks the urine was clear. No cause can be assigned for the attacks; not uncommonly they have come on while he was lying in bed. He states that the right kidney is now the seat of marked aching pain.

Condition before operation.—Bladder was sounded, but no stone was found. Prostate not much, if at all enlarged. Renal dulness on the two sides equal and normal. Right kidney tender. Two species of urine were furnished, one with a large bloody sediment, but without clots, and the other clear and acid, sp. gr. 1022; very slight amount of albumin. Microscopical examination showed no crystalline elements, a few blood disks, granular matter, and a large number of bright fatty-like small globules. Dr. Watson, the patient's physician, had never found any albumin except just after the attacks of hematuria, nor has he ever seen any cast. It was decided to explore the right kidney, either for stone or possibly for cancer, and either to remove the stone or the kidney, as might seem best.

Operation, Nov. 3, 1888.—An oblique incision was made just to the right of the erector spinæ. The lower end of the kidney appeared normal. The finger detected a rather

sharp irregularity deep in the substance of the kidney. The moment it was pressed on we were convinced that it was a stone. A needle was then passed into the kidney, and the point of it grated with great distinctness against the supposed stone. The kidney was now seized with a volsella, and was loosened from the surrounding tissues in order to obtain freer access to it. This was followed by two results: First, very abundant, indeed very alarming hemorrhage, from large veins that were so concealed under the last rib that they were seized with great difficulty, even after the rib was well raised, and when seized they were so friable that the ligatures would not hold. The second result was to disclose the fact that while the small portion of the kidney first discovered was normal, the rest of it was irregular, nodular, and friable, and evidently the seat of a malignant growth. Accordingly, it was determined to remove the kidney, if possible. It was rapidly detached from its capsule by the finger, but it was so anchored internally at the hilum that it could not be brought to the surface, in spite of the fact that he got his entire hand into the cavity of the capsule.

Having proved the impossibitity of removing the kidney by the loin, he had debated the question of attempting it by an anterior incision, but as the difficulty of removal was not the size of the kidney, but the adhesions at the hilum, he concluded not to attempt an operation by this route, as he felt convinced that it would result in the patient dying upon the table. The hemorrhage had been exceedingly profuse, not from any one particular vessel, or from rupture of the vessels of the hilum, but from every point in the kidney and in the capsule the moment they were separated. This hemorrhage was checked by thoroughly packing the wound with sublimate gauze. The patient was put to bed. He became conscious and recognized his family, but died from exhaustion three and a half hours after the operation.

Autopsy.—In order to determine whether the kidney could have been removed more readily by the anterior incision, Dr. Keen made this attempt as the first step in the autopsy. An incision was made in the right linea semilunaris, which gave no more room for the removal of the kidney anteriorly than posteriorly. The ribs projected so far downward that, in order to reach the kidney, it was necessary to insert his entire hand up to the wrist. The kidney lay far up under cover of the ribs, and was as inaccessible from the front as from the back. It was so thoroughly anchored in its position that to loosen it from its bed required force that would have been wholly unjustifiable during an operation, and would have resulted in rupture of the vessels and in immediately fatal hemorrhage. It would not have been possible to reach and tie the vessels in such an inaccessible position. When removed, the kidney was found to be enlarged, nodular, and distinctly cancerous. The left kidney and other abdominal viscera were normal.

On section of the kidney there were discovered some calcareous vessels and one or two points of calcification of the other tissues. Microscopical examination showed that it was an intermediate form between scirrhus and encephaloid, with a decided preponderance in the greater part of the organ of the latter form of the disease.

The diagnosis. This lay most likely between stone in the kidney and cancer of the kidney. Although it seemed unlikely that stone should exist without producing pyelitis, and, therefore, showing some pus in the urine, yet Dr. Keen had known of more than one case of both stone in the bladder and in the kidney in which the urine contained no pus. The repeated hematuria looked very much toward malignant disease, but the kidney was so under shelter of the ribs that it was impossible to detect any tumor, and the dulness was not markedly increased. The enlargement of the kidney was chiefly toward the hilum, and so the dulness posteriorly was little greater than normal. Mr. Henry Morris states that of 30 cases of cancer of the kidney, found in 2610 autopsies, 25 were secondary, and only 5 were primary. The present specimen is undoubtedly a primary malignant tumor, and is, therefore, a rare form of disease.

In the surgical aspect of the case there are two points of interest: First, the needle test for stone. When the kidney was exposed to view, the only healthy portion of it remaining was first seen. Deep under this an irregular, hard mass could be felt, which might easily be a stone. Puncture by the needle convinced us that it was such. Examination of the kidney after death showed us that no stone existed, but that what was felt by the point of the needle was either a calcareous vessel or a calcareous degenerative mass against which the point of the needle grated. It gave precisely the same sensation as a stone would have done. This possible error seems very unusual, and he had never seen it noticed.

Secondly, the advantages of the lumbar or of the abdominal route for removal. As the operation was undertaken primarily for exploration, and no tumor in any sense was discovered, he was clearly of opinion that the lumbar route was the proper one to select. The attempt made at the autopsy shows that the kidney could not have been removed any more readily by the abdominal than by the lumbar incision. The peculiar situation of the mass in question, and the low position of the ribs, resulted in the curious fact that whilst the space between the last rib and the crest of the ilium was only two fingers in breadth, yet the oblique incision here of four inches was long enough for removal, and it could have been still further prolonged anteriorly, if necessary; whereas, the vertical incision from the rib to Poupart's ligament was absolutely limited to four inches, and the kidney was certainly no more accessible by this route than by the other. The removal of the kidney was practically impossible by either method. The inflammatory attachments —especially around the hilum and the great vessels of the kidney—required an amount of force that would have been unjustifiable during life.

Dr. DeForest Willard thought that, as a rule, the anterior median incision offers better opportunities for diagnosis, for examination of the other kidney, and for safe removal. In cases where a stone is suspected, or the presence of pus is probable, the lumbar incision is certainly proper; the operation may be simply a nephrotomy and not a nephrectomy, and then we have better drainage. In simple purulent kidney, it is better to secure drainage and not remove the kidney. The results, so far as life is concerned, are better by this method. In tuberculous kidneys, the results of nephrectomy have been more satisfactory. In Bardenhauer's statistics,[1] numbering some thirty-five nephrectomies, where twenty-five were for purulent kidney of various forms, the mortality

[1] Berlin klin. Woch., October 15, 1888. The Medical News, December 1, 1888.

was not much higher than in ordinary nephrectomy. Out of thirty-five cases he lost ten.

The choice of the incision will depend largely upon the condition of the case, and upon the diagnosis. Many nephrectomies have been performed after the abdominal incision has been made for other purposes, as when the ureter has been cut in laparotomy. He did not know why it was any better, but Schmidt recommended that in such cases the kidney be removed by the lumbar incision. It seemed to him that this would decidedly delay the operation, and would be more likely to cause contamination of the abdominal cavity. He did not think that the results were much more serious in the anterior operation than they were in the posterior.

In regard to the sutures to be employed in *nephrorrhaphy*, he thought that the failures had resulted from the use of catgut. We must employ a permanent suture, which will hold for a long time, and anchor the kidney until it is thoroughly fixed in its position. The question of decubitus is of importance. A month is the shortest possible time in which we can expect any fixation. The use of pads is very unsatisfactory. We are obliged to apply the pad upon the abdominal walls to an organ that lies deep in the loins with the intestines in front of it. We cannot hope to hold it in position by any such means. Therefore the dorsal decubitus should be maintained for a long time.

DR. M. PRICE thought the anterior incision the better, even if after making the diagnosis you close the abdominal incision and remove the kidney by the lumbar method. An incision one and a half inches in length affords ample room for the examination of all the organs. He had twice examined both kidneys through such an opening. In one case of supposed gall-stones, he found the viscera attached to the abdominal wall. After separating them, he examined the kidneys without difficulty, and found them in good condition. In the case where he removed the kidney, he had no difficulty in feeling both kidneys through a small abdominal incision. He thought that if Dr. Keen had made the median abdominal incision, and found the kidneys so seriously diseased, he probably would not have made as great an effort as he did through the lumbar incision.

His impression was that the anterior route was the best for drainage, which, in these cases, is of paramount importance. So much tearing is done in releasing the kidney that drainage for twenty-four or forty-eight hours is necessary, or at least can do no harm. He did not believe that any drain answered its purpose so well as one that can be cleaned by the attendant or nurse. The best method to stop oozing of blood is to keep it cleaned away. Keep no blood in contact with the bleeding vessels. He believed that morphia had a tendency to cause suppression of urine. It also lowered the vitality and assisted in killing the patient. He should not think of using morphia in abdominal cases unless the patients were dying. Where morphia had been used in surgery, and especially in abdominal surgery, he had had cause to regret it.

DR. JOHN B. DEAVER had operated both by the abdominal and lumbar method. He considered that the anterior incision was preferable in cases of solid growths, particularly where they have reached any size. We run greater risks in attempting to break up the adhesions to the capsule by the lumbar incision, where we cannot see what we are doing, than we do through the anterior incision. The proper course is to go through the linea semilunaris. This brings us nearer to the organ, and gives a better opportunity to work to the outer side of the colon, which is important, as the bloodvessels are in relation to the internal layer of the meso-colon, and not with the external layer. In cases of liquid accumulations in the kidney, he did not think that we operated with quite as much facility anteriorly as posteriorly. The lumbar incision affords better opportunities for drainage under these circumstances, but drainage can be satisfactorily accomplished by the anterior method by the glass drainage tube. The abdominal incision affords us better opportunities for the examination of neighboring organs. For purposes of diagnosis it is more satisfactory than the operation through the loins.

There is no doubt that in nephrorrhaphy the proper form of suture is antiseptic silk. He knew of one failure resulting from the use of catgut. It is probably impossible to pass sutures through the capsule of the kidney without also involving the substance of the organ, yet he thought that if we could avoid wounding the kidney it would be better. He had no doubt that the appearance of albumin in Dr. Keen's case after the operation was due to the sutures.

The question of the removal of solid growths of the kidney is largely influenced by the age of the patient. It is almost useless to operate for carcinoma of the kidney in early life or in late life, so that the middle period offers the best chances for a favorable result in these cases.

DR. THOMAS R. NIELSON said that the statistics of the removal of the kidneys for malignant disease are so unfavorable that any operation seems to be almost hopeless; nevertheless he did not think that, in individual cases, this should be a contra-indication if the operation seems to be justifiable on other grounds. In children, the statistics of Dr. Gross, in 1885, were, that in thirteen operations only four recovered from the operation, and these subsequently died from return of the disease elsewhere.

DR. JAMES TYSON said in reference to the etiology of floating kidneys, that he had been compelled to conclude that in the majority of instances it is congenital. He had seen most typical instances of floating kidney in men, and had seen it more frequently in women who have never borne children than in those who have had children. Even in those cases where it is supposed to have been caused by accident, that in all probability the condition has been congenital, and, if anything, only exaggerated by the fall. In regard to the treatment of floating kidney by the use of pads, etc., he had never seen any advantage result from such devices.

DR. J. M. BALDY said that there is great importance in drainage in kidney operations. A tube that can be kept clean, is the drainage tube *par excellence*—the glass tube is such.

In one case of malignant disease, in which he witnessed the removal of the kidney by the abdominal incision, the hemorrhage not being entirely controlled, the peritoneal cavity was entirely closed off from the bed of the kidney by stitching the cut edges of the peritoneum together; prior to this, however, a counter-opening was made through the muscles of the back, and thus good drainage secured. The patient made a good recovery.

Dr. John B. Roberts referred to a case of cure of movable kidney without operation. A boy, seven years of age, was referred to him four years ago by Dr. M. O'Hara. At irregular intervals the patient was seized with severe pain in the left side of the abdomen, and with this there was the appearance of a tumor in the hypochondrium and total suppression of urine. Various theories had been held to explain the condition. The only conclusion that he could reach, although this was not concurred in by Dr. O'Hara, was that the boy had a floating kidney, and that at the times of the paroxysms the ureters became twisted, causing the suppression of urine and the intense pain. The boy never had any pain or trouble with the urine except when the tumor was felt. At his suggestion Dr. O'Hara had made a pad which pressed against the left hypochondrium. This was worn for a short time. The boy then passed from his notice, but he learned a few years ago that he had perfectly recovered. There is, of course, in this case an element of uncertainty in regard to the diagnosis. When he looked into the literature of this subject, he was surprised to find how much stress was laid upon the possibility of the ureters becoming twisted, and the flow of urine being interfered with.

In connection with the question of the lumbar incision he referred to an accident which he had in an attempt to explore the kidney for a supposed renal calculus. After making the incision down to the kidney, he determined to enlarge it a little. The diaphragm hung down in a fold and was readily seen. He made the incision a little longer in the upward direction, and made a minute perforation in the diaphragm where it is attached to the spinal column. There was a loud whistle as the air rushed into the pleura. He put in a suture and closed the opening, and no harm was done; but for a few days the patient insisted that the bandage was too tight, because he could not breathe freely. The pain which the patient had felt disappeared after the operation, although no stone was found. He went home before the wound had closed, and a number of months later died of some obscure disease.

It is important to recollect, when operating close to the vertebral column, that the posterior attachment of the diaphragm near the middle line extends further down than might be realized from watching its loose muscular curtain exposed in the wound.

Dr. W. W. Keen thought that there was no doubt that in the case of a large tumor of the kidney, particularly a large solid tumor the size of which cannot be diminished by tapping, the position taken by several of the speakers is correct—that the anterior incision is the proper one. Where there is a small growth, or a stone in the kidney, or the operation is an exploratory one, he could not think that the anterior incision is the best. Statistics certainly show that the lumbar incision is attended with much less risks than the anterior. Where there is no reason to suppose that an unusual amount of room will be required, he thought the lumbar incision is the proper one to employ.

It has been also suggested that possibly the anterior incision in the present case of nephrectomy would have given so much information that he should have decided not to operate. He did not think that he should have reached any such conclusion, for it was not the character of the growth, but the adhesions at the hilum that interfered with the removal of the organ, and these could not have been determined until the operation was in progress. He thought that it would have been as impossible to remove the kidney by the one method as by the other. He had the pleasure of seeing Dr. Steinbach's case just prior to the beginning of the operation, and he certainly was convinced that it was a case of enlarged gall-bladder with gall-stones. The slightest movement caused a grating of one stone upon the other. The tumor was in the position of the gall-bladder. He never before saw a kidney so displaced. The long axis, instead of being vertical, lay in an antero-posterior position, and the upper end of the kidney occupied precisely the position of the gall-bladder. The mistake in diagnosis, under these circumstances, was very natural.

Alexander Hadden, M.D., in the Chair.

Dr. C. G. Currier read a paper on

THE EFFICIENCY OF FILTERS AND OTHER MEANS EMPLOYED TO PURIFY DRINKING-WATER, BACTERIOLOGICALLY CONSIDERED.

(See page 425.)

Dr. T. Mitchell Prudden said that a good deal of objection had been made to the work of bacteriologists, and largely on the ground that it had been found very difficult by them to detect the typhoid bacillus in drinking-water. It was purely a technical matter, and the trouble was the difficulty of distinguishing the typhoid bacillus from other bacilli which closely resembled it. This applied principally to large bodies of water, since in small bodies of water the typhoid bacillus could be much more readily recognized. Dr. Prudden then spoke of the serious epidemic of typhoid fever which occurred in Providence, R. I., in the early part of the winter, and to which reference had been made in the paper. It seemed that last autumn typhoid fever was prevalent in a village of French Canadians situated on the river from which the water-supply was derived, and about half a mile above the city. The sewage of the village did not pass directly into the river, but the inhabitants emptied the dejections from typhoid fever patients into privy vaults and also upon the banks of the river. In November there was an unusually severe rain-storm, which washed a large amount of material from the banks into the stream, and early in December the death-rate in Providence rose to 127. Notwithstanding the fact that the flow of water amounted to over seven million gallons per hour he was able to detect a few typhoid bacilli, together with a large number of ordinary water bacilli, in the charcoal filter referred to by Dr. Currier. It consisted of an outer and inner metallic ball, and was so arranged that the water could pass around the charcoal, while there was an orifice half an inch in diameter from which the water escaped.

Dr. John C. Peters said that it seemed that to-day the water of both Berlin and London was more free from contaminations than that of New York. The filter-beds employed in purifying the water-supply of London were mostly of sand, the efficacy of which Dr. Currier had spoken of in the paper. Dr. Peters said that during

the past four years he had paid considerable attention to the condition of the Croton water-supply, and he had been glad to learn that the State Board of Health had undertaken the work of keeping it as pure as possible in the future. At present the amount of contamination that got into the water was very great; yet it was a fact that during the past season there had been a smaller number of cases of typhoid fever reported in the city than for a long time before.

DR. R. C. M. PAGE said that for a number of years past, up to last summer, he had used in his house a globe filter about three inches in diameter, containing clean sand. At first tin was the material used in its construction, but afterward copper was substituted for it, as the tin soon rusted out. Last summer, in Paris, he met with the filter spoken of by Dr. Currier in the paper, which he now exhibited, and which he said was the only filter which had really ever proved satisfactory to him. It somewhat resembled the Pasteur filter, and consisted of a large disk of porcelain backed by carbon. It allowed the water to pass much more quickly than the Pasteur filter, and two quarts an hour could be obtained from it. He thought that the water from such a filter was better than distilled water, as a rule, since one could never feel sure that the latter, as ordinarily supplied, was freshly distilled.

DR. J. LEWIS SMITH said that from recent experiments referred to in a lecture by Jules Simon, of Paris, it would appear that a filter which would arrest the passage of the Klebs-Löffler bacillus, would permit the passage of ptomaines resulting from microbic action. This seemed to him a very interesting point.

DR. AGRAMONTE inquired if Dr. Currier had ever made an examination of the Apollinaris water which was so largely used at the present time, and so highly recommended for its purity.

DR. CURRIER stated that he had not examined this particular water.

DR. JOHN C. PETERS said that he had reason to believe, on good authority, that not one-half of the Apollinaris water put upon the market was derived from the Apollinaris Spring. A considerable proportion of it, at least, was artificially prepared at Antwerp, where this could be done very cheaply.

DR. CURRIER inquired if any of those present could inform him what was the effect of distilled water upon children and youth, particularly as regards the lack of salts, of which the water was deprived by the process of distillation.

DR. H. JACOBI said that the salts in drinking-water that could be expected to be beneficial to the system were the chlorides and phosphates. The Croton water, when pure, was regarded as a very excellent water, and yet it came very near distilled water in regard to the absence of salts. Some of the hot spring waters in Europe also contained very few salts. He believed, however, that we all suffered more from the presence of salts in drinking-water than from the lack of them. When we did drink hard water, the salts merely passed through the system without being utilized. It was, unquestionably, a fact that children, as well as older persons, took into their systems, from milk and other liquids, and from both farinaceous and animal foods, more salts than they could possibly utilize. Hence he did not believe that distilled water was detrimental to health on account of its lack of salts.

CORRESPONDENCE.

THE VALUE OF RHUS TOXICODENDRON IN RHEUMATIC AFFECTIONS.

To the Editor of THE MEDICAL NEWS,

SIR: The discussion which appeared in the columns of your journal of April 6th, relating to the treatment of sciatica, has attracted my attention, and having been over the ground traversed by most of the participants, I take the liberty of suggesting a comparatively new remedy for the relief of such cases. The hypodermatic use of osmic acid and the glass rod have not come within my personal observation, nor have I had experience with the excision of the affected nerve, nor with stretching, although I have seen the operation. Few persons, however, are willing to submit to this heroic method, since no guarantee is afforded that the results will be successful. The application of the instrument devised and used so successfully by Charles Baunscheidt has frequently been followed by the very best results, but I have not been able to determine just the class of cases in which it would answer. That it is a successful method of applying counter-irritation cannot be denied, and where patients do not object, there are many instances in which it may be used with great advantage, the indications for its use not being confined to rheumatic affections. Some years ago I recall the circumstances attending two cases of sciatica, both of which were operated upon in this way the same day. In one case there was no benefit whatever, while the other was immediately and permanently cured. The first case was that of an elderly gentleman who had been under treatment for some time and whose history will be related as offering us some interesting items in connection with the care of such cases. The second case just mentioned was that of a lady aged about thirty-five, who had been suffering for some months, and was somewhat anæmic, and in addition there was prescribed for her a suitable tonic.

The remedy which I would put forward as a material addition to our therapeutics in the treatment of many of the more obscure manifestations of rheumatism is rhus toxicodendron, a remedy which has attained some local celebrity in different sections of this country, and one too, which has been used by a number of practitioners abroad. The drug is referred to by Dr. Phillips in his excellent treatise, and from this we learn that it was first brought to the notice of the profession in 1798 by Dufresnoy, a physician of Valenciennes. Later, some interesting observations were made upon it by Alderson of England, and in 1836 it was included in the London Pharmacopœia. Dr. Phillips suggests that rhus is valuable in various subacute and chronic rheumatic affections of fibrous tissues, and that the synovial membranes seem to be less amenable than the fibrous structures, such as tendons, ligaments, and fasciæ. He also recommends its use both locally as a liniment, and internally in the later stages of rheumatism, "when the patient suffers still from wearing stiffness, and aching of subacute character in the joints." It is also recommended in the case of incontinence of urine, and is referred to by Drs. Whitla and Brunton in their respective works.

In the vicinity of Chester, a few miles south of this city, it is said to grow in luxuriant abundance, and in

that section its value has attained great, and judging from reports which have been made from time to time, warranted popularity. The poison sumach is also referred to in the latest edition of the U. S. Dispensatory, but not in very complimentary terms, the authors intimating that it is an extremely active poison and probably dangerous to be used as a remedy. Some reports have appeared in current medical literature, but as none of them, so far as I know, covers the ground upon which I have based my treatment, it may be worth while to offer several typical cases by way of illustration of the different directions in which its application may be anticipated, for the relief of diseased conditions. It may be mentioned here that my observations extend over a period of nearly three years, and that my first published communication on this subject appeared in December, 1887.

Case I.—My first case mentioned above was a gentleman, aged about sixty, who had been under treatment two years previously for the same affection, and was relieved by the deep injection of chloroform, together with the occasional application of the faradic current. At the time when he first came under observation he was suffering from cardiac derangement which culminated, from time to time, in attacks of unconsciousness, attended with great physical depression; the real cause probably being due to fatty degeneration with its attending circumstances. Appropriate treatment, however, overcame this disposition, and a year later he complained of sciatica. Although scarcely able to walk, he came to the office every few days, and shortly was able to walk several miles daily without any embarrassment, and the pain in the hip was comparatively easy. The following spring the pain again appeared, if possible, worse than before, and thinking I had exhausted the resources of the pharmacopœia, he consulted an irregular, who faithfully sand-papered him, and afterward applied some stimulating embrocation, which nearly drove him wild; in addition to this, he volunteered the information that his hip was out of joint, and that, although he could put it in place again, the bone refused to stay in position. This style of medication was continued for some weeks, and the patient then consulted an electrical physician, who guaranteed to effect a cure within a reasonable time, but to make the matter more binding, he took a retainer of twenty-five dollars in advance. Electrical treatment was continued for about two months, but without that relief which the patient had expected, and the expense proving a serious objection, it was discontinued.

This patient again consulted me in the September following, some time after the other methods of treatment had been discontinued, and was placed upon the salicylate of sodium, together with strychnine sulphate gr. $\frac{1}{30}$ after meals, and after a time it was deemed advisable to resume counter-irritation, but the patient strongly objected to the injection of chloroform, although he was willing enough to have a blister. Instead, however, Baunscheidtismus was adopted, but without any apparent benefit. Later on, a thapsia plaster was applied, and seemed to serve the purpose for the time being, but the pain was soon as severe as before.

During the interval of relief afforded by the thapsia plaster treatment had been discontinued, so that at the expiration of two weeks, it may be said, this patient was wholly free from the influence of any medication whatever, and it was at this period that rhus was ordered, one drop of a solution of the tincture, three or four times daily, and in less than a week the sciatica had yielded. The best part of the story is, that now more than two years there has been no reappearance, and the extra "lift" on the boot-heel, which had been added to make up for the dislocation, and which was discarded at my suggestion, has never been reapplied.

Case II.—About five years ago, a farmer, aged fifty, consulted me on account of lameness in one knee, from which he had suffered for fifteen years, and was relieved by the local application of an ointment of salicylic acid and lanolin. Two years later, he applied for the relief of lameness of the shoulder, which had developed gradually, and resembled the lameness of the knee which had crippled him for so many years. Here the rhus was exhibited internally in small doses and applied externally as a liniment, and in the course of a few days, the pain and stiffness had disappeared, and the patient has since been free from any of the symptoms of rheumatism.

Case III.—A farmer, aged about sixty-five, was attacked last summer with sciatica of very painful nature, which seriously interfered with his work and his comfort, disturbing his rest at night. In this case there was not a distinct history of rheumatism, but there was a history of general debility, and while we cannot charge rheumatism to that alone, there frequently seems to be a direct association of the two. It is sufficient to add that the patient recovered from the use of rhus alone; no medication preceded it, and none has followed.

Case IV.—Whether varicose veins may be regarded as one of the manifestations of rheumatism, is a question which will require further elucidation, but the fact that the remedies which are useful for the relief of one affection are often of benefit in the treatment of the other, would lead us to suspect some occult relationship. Mr. B., aged thirty-five, unfortunately was subject to both, and when one did not trouble him the other did, so that life became a burden to him. The rhus was taken in moderate doses for a time in the hope of relieving the rheumatism, and his surprise was all the greater when he found that the varicose condition of the veins of the legs was greatly benefited as well as the rheumatism. This patient eventually recovered, notwithstanding the assertion of numerous physicians that nothing could be accomplished for him without an operation, and rhus was the only remedy.

Case V.—The following case is fresh in my mind, the patient, a married woman, aged thirty, having come under observation for the first time about two months ago. At each menstrual period, and at other times when she was compelled to work hard, the enlarged veins of the legs were almost unbearable, and it was almost impossible for her to rest at night. Small doses of rhus removed all pain in the course of a few days, and since that time she has been taking the drops for the most of the time; there has been no pain of any consequence, either during the menstrual molimen, or when she has been working hard in looking after a large family. The puffiness of the vessels has not disappeared, but their appearance is most promising, and it seems as though greater rapidity could be secured by the application of a suitable bandage, provided the patient appreciated the necessity of keeping it in place.

Case VI.—It not infrequently happens that a physician is called upon to relieve attacks of "cramps in the legs," occurring at night, the patient saying that suddenly he is awakened from a sound sleep by cramps, that it is impossible for him to remain in bed, and he jumps out on the floor. Most persons subject to attacks of the kind have provided themselves with a strong cord for such emergencies, and at the moment of attack they coil it around the leg once or twice, then, holding an end in each hand, they give it a short, strong jerk, which is said to relieve the cramp quicker than anything else.

Mr. G. had suffered from this trouble for several years, and came to me for relief. He had a cord, and he also told me that a doctor once gave him medicine which relieved him for a long time. Knowing the value of rhus in relieving the pain which affects varicoses, I concluded that it might be of some value here, and was not disappointed. Treatment was a success, and has been adopted with like results in other cases of the same character.

Case VII.—Mr. B., aged thirty, is a successful and apparently happy farmer, who has been engaged in his present work for the past two years. His health is impaired by reason of rheumatic symptoms, and for the last five years, he says, the same conditions have existed to a greater or less extent. Previous to the time of adopting farming as a business, he had been engaged as a private coachman, and received good wages without having to work too hard or unnecessarily expose himself to inclement weather. He complains of fugitive pains about the larger joints, and says the water causes a very unpleasant sensation when passed from the bladder; there seems to be an unusual sensation of heat, and yet he does not pass a very large quantity, but rather less, he thinks, than in former years. An examination shows that it is normal as to gravity, but the acidity is particularly marked, and when a drop is placed under the microscope the field is dotted with crystals of different varieties, probably uric acid in combination.

This patient had been a faithful patron of the doctors, first the regular, then the irregular, and his last exploit was the submission of his case to a druggist. The last was the worst of all, and he finally rebelled, and concluded to try the whole thing over again. A weak solution of the tincture of rhus was ordered, five drops to be taken three times daily in a little water. When he reached home and compared the small vial containing his medicine with the formidable bottles he had been in the habit of getting, he was inclined to regard the matter in the light of a good joke, but concluded to undertake it, thinking my purpose was to learn if he would take the medicine faithfully. In a few days he reported that he was able to report progress, and the medicine was continued for another week, except that the dose was reduced to twelve drops daily. Now, at the expiration of ten days from the time treatment was first instituted, this patient reports that the trouble with the water has ceased, that the rheumatic symptoms have subsided, and that he feels better than at any time for five years.

In concluding this somewhat lengthy communication, which could be extended indefinitely, as I use the remedy nearly every day, let me suggest to the gentlemen engaged in the discussion to which I have referred, that it would be interesting to have the benefit of their observations regarding the value of this remedy which I have inadvertently called new, which holds out such great promise as a therapeutic agent.

JOHN AULDE, M.D.

The Medical Society of the County of New York Sustained.—Judgment has been entered on a final order of Judge Ingraham, of the Supreme Court, sustaining the Medical Society of the County of New York in its expulsion of Dr. James O'Reilly for practices in violation of the Society's code of ethics.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 9 TO APRIL 15, 1889.

BYRNE, CHARLES C., *Surgeon* (U. S. Army).—Promoted Surgeon, with the rank of Lieutenant-Colonel, to rank from March 29, 1889.

MUNN, CURTIS E., *Assistant Surgeon.*—Promoted to Surgeon, with the rank of Major, to rank from March 29, 1889.

By direction of the President, PAUL R, BROWN, *Captain and Assistant Surgeon*, will report in person to Brigadier-General John R. Brooke, President of the Army Retiring Board, at Omaha, Neb., for examination by the Board.—Par. 9, *S. O. 80, A. G. O., Washington*, April 6, 1889.

By direction of the President, the State of Wisconsin is transferred from the Department of the East to the Department of Dakota.—*G. O. 36, A. G. O, Washington*, April 6, 1889.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY, FOR THE WEEK ENDING APRIL 13, 1889.

HEFFENGER, A. C., *Passed Assistant Surgeon.*—Found unfit for duty at present, by the Retiring Board, but not permanently incapacitated for active service, and granted one year's leave of absence for medical treatment.

DU BOSE, W. R., *Passed Assistant Surgeon.*—Detached from the U. S. S. "Constellation," and ordered to the Practice-ship "Jamestown."

LOWNDES, C. H. T.—Commissioned an Assistant Surgeon in the U. S. Navy, March 13, 1889.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING APRIL 13, 1889.

GODFREY, JOHN, *Surgeon*—To proceed to Poughkeepsie, N. Y., on special duty, April 10, 1889.

MEAD, F. W., *Passed Assistant Surgeon.*—To report in person to the Supervising Surgeon-General, April 3, 1889. Detailed as Acting Chief Clerk Marine-Hospital Bureau and Attending Surgeon port of Georgetown, D. C., April 10, 1889.

WHEELER, W. A., *Passed Assistant Surgeon.*—Relieved from duty at Buffalo, N. Y., to assume charge of the Service at Norfolk, Va., April 3, 1889.

DEVAN, S. C., *Passed Assistant Surgeon.*—Relieved from duty as Acting Chief Clerk Marine-Hospital Bureau and Attending Surgeon, to assume charge of the Service at Buffalo, N. Y., April 3 and 12, 1889.

PETTUS, W. J., *Assistant Surgeon.*—Granted leave of absence for four days. April 6, 1889.

STONER, J. B, *Assistant Surgeon.*—To rejoin station (New York) as soon as practicable, April 11, 1889.

ORIGINAL ARTICLES.

ON THE TREATMENT OF THE SO-CALLED PERITYPHLITIC ABSCESS.[1]

BY ROBERT F. WEIR, M.D.,

SURGEON TO THE NEW YORK HOSPITAL, PROFESSOR OF CLINICAL SURGERY, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK

THE subject of the origin and treatment of perityphlitic abscess has been largely dwelt upon within the last few years in the various medical societies in our principal cities, and notably quite recently by the leading physicians and surgeons in the important medical centres of Boston and Philadelphia. Though nothing specially novel can be presented in the following remarks, yet reiteration of the principal views in connection with this subject will be of importance, and especially so, it is thought, to the general practitioner. The latter will find, as his experience grows, that there are apparently two classes of perityphlitic abscesses, one of which progresses with comparatively few alarming symptoms, and develops into an abscess which either opens spontaneously, or which he, if he has recognized from the usual symptoms the presence of pus, opens with the knife, whereupon the patient, as a rule, promptly gets well. Again, a second form presents itself with more or less sharply marked symptoms of peritonitis, with the formation subsequently of a tumor in the region of the cæcum, which in due time, like the preceding one, resolves itself into an abscess. He may also meet cases in which a fulminating peritonitis destroys life in a few days. The consideration of this latter condition of affairs can, however, be laid aside for the present.

The practitioner will find it difficult to reconcile to himself that all three of these varieties have a common origin. If he consults his text-books he will learn that there are two distinct varieties therein spoken of. Some of these authorities he refers to will say that the inflammatory action is from the beginning in the connective tissue outside the peritoneal cavity behind the cæcum; and others that the inflammation has begun in the peritoneal cavity from a lesion of the cæcum or appendix and has gained the connective tissue outside the peritoneum through a perforation of the adhesions gluing the visceral and parietal peritoneum together; and finally, the latest works on this subject will tell him plainly and positively that the inflammation and abscess are from the beginning in the peritoneal cavity, and that the pus only approaches toward the surface by a natural destructive process common to abscesses generally. Among the most noted names that can be adduced in favor of these abscesses originating in the connective tissue posterior to the cæcum, are those of Bamburger, who, in 1853, stated that this view was a correct one, though he admitted that the peritoneum might be secondarily involved and so give rise to a circumscribed or general peritonitis. Oppolzer likewise, in 1863, remarked that perityphlitis meant an extra-peritoneal inflammation of the connective tissue behind the cæcum; he, however, also said that it was difficult to differentiate the diagnosis between the abscess thus resulting and that coming from ulceration and perforation of the appendix vermiformis.

It is hardly worth while to go further into a citation of the various writers who have supported these different views concerning the cause of a perityphlitic abscess. The recent articles of Fitz and others interested in the subject have amply demonstrated the incorrectness of the views of the observers first named. It is now clear to every one who has given attention to this subject that all these abscesses originate in an inflammation, simple or gangrenous, or in a perforation, and more commonly it is the latter, of the appendix vermiformis.

That the abscess might be due to a perforation of the cæcum is conceded, though such perforations are found at post-mortem examinations to be commonly caused by an abscess opening into the bowel or to necrotic ulceration from an over-distended colon from a stricture further down the intestinal tube. Cæcal perforations of any kind are, however, very rarely met with.

While this prominent fact of the inflammation or perforation of the appendix as a cause of perityphlitic abscess has now been admitted by most surgeons, yet not a few still cling to the belief that the perforation takes place in such a way that an opening, small in size, is made directly from the appendix through the parietal peritoneum into the sub-peritoneal connective tissue behind the cæcum. Two serious objections have been raised to this belief. The first objection comes from the recent observations of Mr. Treves in respect to the peritoneal covering of the appendix and cæcum itself. It is now

[1] Read at the meeting of the Medical Society of the State of New York, February 6, 1889.

the common property of the profession, through this surgeon's dissections, that these two parts of the intestinal tract are entirely covered by peritoneum. This is not a new discovery of Mr. Treves. He has only proclaimed it loudly and at a most opportune time.

Bardeleben, in 1849,[1] from an examination of one hundred and sixty cadavers, asserted as a certainty that the cæcum is completely surrounded by peritoneum, and lies so freely movable in the peritoneal cavity that it can be pushed upward and laterally. He, moreover, said at this early period that it follows, if this is corroborated, that the definition of a perityphlitis as an inflammation of the connective tissue of the posterior surface of the cæcum cannot be justified.

Luschka,[2] the distinguished anatomist, in 1861, declared that in the fœtus the peritoneum surrounds entirely the cæcum and appendix, and that this is a usual thing, and is, as a regular rule, to be found in post-fœtal life. Moreover, Luschka states that one cannot open the cæcum and appendix without opening the general peritoneal cavity; and he, too, remarks that perityphlitis, as it was then commonly regarded, was an impossible condition, unless there had been previous adhesions.

Corroboration of these views has been made by Dr. Richardson, of Boston,[3] and I have myself in thirty autopsies had the position of the cæcum and appendix carefully observed by Dr. Ferguson, pathologist to the New York Hospital. His report is to the effect that the cæcum and appendix were covered entirely by peritoneum in twenty-eight instances, the cæcum only partially covered in one instance, and it was not stated in another. It may be mentioned as a matter of some interest in this connection that in sixteen of the cases the appendix rested beneath and posterior to the cæcum. Treves has found this to occur in eighteen per cent. of the cases observed by him.

While ranging myself with those who strongly believe in the origin of these abscesses in an inflammation or perforation of the appendix vermiformis, yet I must confess from the clinical standpoint it is rather a difficult matter to prove this. Out of an experience of twenty-six abscesses of this sort that have been opened by me, in only some eight of them have I been able to recognize that the inner wall of the abscess was made up of loops of intestine bound together by adhesions. This experience has come to me, however, only within the last three or four years. I believe had I fairly tested this question in my earlier cases this number would have been increased, but it must be clear to every one that it is a test that cannot be applied with much thoroughness on account of the possible risks connected therewith. In fact, I do not advise that the matter should be determined in this way. I have elsewhere demurred to such explorations, or even to washing out the cavity of the abscess after it has been opened with liquids, plain or medicated, lest the limiting adhesions of the peritoneal boundaries of the abscess should be damaged, and the patient's safety jeopardized. I believe, moreover, and this my experience confirms, that in many cases it is utterly impossible after the abscess is opened, and it is explored gently and judiciously by the finger, that the surgeon can determine whether the abscess is external to or within the peritoneal cavity. I do not think that evidence of a negative character thus obtained is worth anything at all in settling this question.

I have, therefore, been led to see if a solution could be arrived at by considering a large number of autopsies of this affection. I have taken pains to gather indiscriminately from the *Index Medicus* 100 cases of perityphlitic abscess, where an autopsy has been obtained, and on analyzing these reports have obtained the following result. Out of a total of 100 autopsies, I found that the appendix was perforated 84 times; that it was inflamed and not perforated 3 times; that the cæcum was perforated 4 times, 2 of which were due to ulcerations proceeding from without inward—in other words, from abscesses opening into the cæcum; in 9 cases the condition of the cæcum and appendix was not stated.

As to the site of the abscess, which was an important fact to be ascertained in these 100 autopsies, 22 of them showed intra-peritoneal circumscribed abscesses; 13 intra-peritoneal abscesses and general peritonitis; 57 general peritonitis without abscess; and in but 4 instances was there an extra-peritoneal abscess; in 10 the condition was not stated.

Now this is a very strong point in favor of the propositions with which I have started: first, that these abscesses are invariably due to inflammation or perforation of the appendix vermiformis; and, second, that, as a rule, the abscess itself is developed within the peritoneal cavity. Not only out of the 100 cases were there only 4 extra-parietal abscesses, showing the rarity of this form of abscess, but also it is to be remarked, that in all these 4 there was a *large* communication between the intra- and extra-peritoneal portions of the abscess. Putting it in a different shape, it can be said that in no instance out of the 100 autopsies did there exist the gluing together of the appendix with the parietal peritoneum, and a primary escape of the contents (fecal or otherwise) of the appendix into the connective tissue by boring through this adhesion, and by the

[1] Ueber der Lage des Blinddarms beim Menschen. Arch. f. Patholog., Anatomie u. Physiologie, Bd. ii. S. 583, 1849.

[3] Boston Med. and Surg. Journal, February, 1888.

subsequent development of pus in the extra-peritoneal tissues.

There was another fact developed in connection with the examination of this collection of autopsies which must be of great importance to the physician, for he it is who sees the cases in their inception. It is this: that in only one case was the cæcum more than ordinarily filled with feces. Now, if there is anything else that is more firmly fixed than another in the practitioner's mind it is this: that the majority of troubles in this region are due to an accumulation of feces in the cæcum, and it is a rule almost prevalent in the medical profession that a purgative should initiate the treatment of these cases. It must be conceded that if it be correct, or if it be presumably correct, that the inflammatory conditions are most likely to originate from a perforation of the appendix, then this fact of itself should preclude the administration of a purgative, of even an enema; and much more would this direction become an absolute one when it is now taken into consideration how rarely stercoral accumulations are met with in this affection. Even catarrhal conditions as factors in the disease are scouted at by Treves.

The facts presented by With are likewise very convincing in this direction. This observer presented, in 1880, a series of 30 cases treated in their beginning by himself, or by his colleagues, after the ordinary method, with the result of 40 per cent. of deaths. In 1884 he again[1] reported a series of 50 additional cases similarly met with, of which only 16 per cent. died. His treatment, however, was entirely different. Purgatives, rectal injections, etc., were sedulously avoided, opium was administered as soon as the disease was encountered, and the patient immobilized as far as practicable, urination and defecation being accomplished with the greatest care and freedom from motion. I can confirm myself, in two instances, the good results of this strenuous treatment instituted in the very beginning of the disease, that is to say, when it may be inferred that the perforation is about to occur or has just taken place.

With these facts in hand, the way is before us to appreciate the proper treatment for these apparently varying affections. Indeed, the aim of this paper, and the aim, I take it, of all the papers entertaining this view that have been published in recent years, is to force upon the mind of the profession, both medical and surgical, the important fact of the *origin* of this disease, because, as With himself states, with this kept constantly in view a proper treatment is more likely to be followed; either the medical one of immobilization, or, if this should prove of no avail, that the surgeon should stand, knife in hand, ready to use his instrument as occasion may demand.

[1] La Péritonite appendiculaire. Copenhagen, 1884.

I do not intend by this picture to give rise to the idea that in every case surgical interference should be immediately resorted to. I have learned by experience that many cases of moderate severity do not go beyond the stage of plastic exudation and subside without abscess; also, that some few abscesses disappear by a presumed opening into the bowel—not always to be proved. I know that delay may be safely resorted to, from the progress of some of the twenty-six cases of operations which have occurred under my own charge, wherein a comparatively late incision was made. This occurred in nearly all of them, not, however, from my own choice, but because they were either hospital cases that came late under my observation, or they were seen in consultation in private practice after the disease had already existed some time. In this number of cases only one death has occurred, and that from an abscess of tubercular origin and in a phthisical patient in the last stages of his disease. Yet though all these, save that one, recovered, a good many of them had a very narrow escape from death by reason of the extensive suppuration, or the threatened sepsis that followed the retention of pus in a large, irregular cavity, or, in some cases, by the prolonged fecal discharge.

I do not know that the lateness of operation influenced this latter point much. Still, the statistics afforded by Noyes, quoted elsewhere,[1] bear out the conclusion that the earlier the safely progressing or subacute abscesses are opened, the better are the chances of the patient. Out of 100 cases Noyes found that in 88 operated upon after the eighth day 17 per cent. died, and of 12 operated upon before the eighth day, 8½ per cent. only died. There is also a risk that the patients carrying these slowly progressing abscesses are exposed to, and it is that the abscess itself may burst into the peritoneal cavity. In 67 cases collected by Dr. Bull, 8 burst into the general peritoneal cavity, and in 12 collected by With, 6 terminated in the same way. It will be remembered that, of the 100 autopsies cited above, in 13 of them there was a limited abscess associated with general peritonitis. The latter was believed, in many of these cases, to be due to a giving way of the soft adhesions circumscribing the original abscess. Furthermore, there are the risks of portal phlebitis with external or internal suppuration of the liver, and pyæmia to be encountered, the longer the pus is retained within the system.

Therefore the rule has been laid down, and in my judgment it is a wise one here, as elsewhere in the body, that as soon as pus is recognized it should be evacuated. Whether a surgeon should

[1] A Plea for Earlier Operation in Perityphlitic Abscess. Weir: Medical Record, June 11, 1887.

resort to measures for determining the presence of pus, such as the use of the aspirating needle or the making of an exploratory incision, will in any given case depend upon the condition presented by the patient. In other words, if the disease be acutely progressing, the surgeon will at once be called on to decide whether the patient will incur most danger from the progress of the disease or from operative interference.

In the case of a slowly progressing tumor without any or with slight peritoneal symptoms, or with those which may have passed away, or ameliorated within twenty-four hours, one need not always feel obliged to hasten to determine whether pus is present or not. The likelihood of there being simply some exudative fibrinous process is quite as great. I have myself been accustomed to keep such patients under careful observation for three or four days, and bide my time until some elevation of temperature, some chill or sweating, or some increase in the size of the tumor indicates that more than such an exudation is present.

I am sometimes compelled to take this course in the earlier days of attacks of this sort, even when unwilling to do so, by the wishes of relatives, or by that more commanding objection, the reluctance, positively expressed, of the attending physician to consent to the employing of surgical measures. I have so far not been able in these milder cases to operate earlier than the fourth day, though my inclination leads me more and more to diminish the period of delay. In those cases, however, where there are decided symptoms of peritoneal involvement over a considerable area, and after such marked symptoms have had a duration of twenty-four hours without any subsidence and are associated with the concomitant symptoms of vomiting and elevation of temperature, then I believe we are justified in interfering without further delay, whether a tumor be present or not. If a tumor, however, does exist, then the question of the advisability of aspiration may be raised, and if decided on this may afford another evidence of the necessity for an immediate operation.

The value of this means of exploration is more commonly realized in those cases where the disease has existed more than forty-eight hours. The needle is usually introduced at a point just over the site of the appendix—that is to say, almost an inch and a half above and nearly the same distance inside of the anterior superior spinous process—and is then carried backward or downward toward the appendix; or it may be thrust inward, and somewhat downward at a point just above the middle of the crest of the ilium, hoping in this latter direction to detect an abscess that may run upward in the right dorsal gutter, and which is erroneously spoken of as being extra-peritoneal in character or of a peri-nephritic location.[1]

I may insert here (as it has previously been omitted) in this connection, that in the one hundred autopsies referred to in the early part of this paper there were seven instances where abscesses had formed in this region, *all within the peritoneal cavity*, and that in two of them the purulent matter had advanced as far as the posterior part of the liver, being limited internally by adherent intestines. Individually I believe that the abscesses of perityphlitic origin which are here found are located primarily, if not during the whole course, in the peritoneal cavity.

Concerning the usefulness of aspiration it must always be kept in mind that, while its employment may reveal the existence of pus, a failure to draw out this through the needle does not prove that pus is not there. Its use, moreover, is attended by some slight risk. When employing it in cases where a tumor was only suspected or could not be clearly and definitely made out, the thought has often come up to my mind that the point of the needle might perhaps perforate a distended bowel. This probably is not of any great matter unless the distention exists to a considerable degree, but the possibility of its doing damage to a normally situated or to a displaced iliac vessel, vein or artery, has often occurred to me. In order to avoid the risk of an extravasation of fetid pus that may come on from this exploration, into the peritoneal cavity, or along the track of the needle through the muscular tissue of the abdominal wall (the occurrence of which I have demonstrated in two instances), I prefer always to follow the revelation of the presence of pus by the needle by making the required incision at once.

I think in our present status that it will go without saying that in those instances in which there are signs of spreading or purulent peritonitis (even though no tumor is recognized in the iliac fossa, either by the ordinary examination or with the patient under anæsthesia) immediately laparotomy is demanded from the nature of the case, provided the general condition of the patient is not too much weakened by the practitioner's delay.

In the first-named variety of abscesses—the milder form of the disease—the incision can, as a rule, be made over the most prominent portion of the tumor; or, in general terms, parallel to Poupart's ligament and running along its outer part and the anterior portion of the crest of the ilium. If the abscess runs further backward the incision is carried in that direction also. In some few instances, as in the surgical treatment of a supposed circumrenal or

[1] A case (read as this proof is corrected) has recently been reported by Coupland in the British Medical Journal, March 23d, where a perityphlitic lesion had caused a subdiaphragmatic abscess.

hepatic renal abscess, the incision must be made vertically or obliquely in the space between the crest of the ilium and the ribs, or in the subdiaphragmatic form along the ribs, or possibly through the pleural cavity itself. But in those cases where there are evidences of spreading peritonitis with or without the presence of a tumor, it is much better to make a tolerably extended incision along the outer half of the right rectus muscle, the upper end of which should reach to the level of the umbilicus. After the muscular layers are divided the surgeon can readily recognize when he comes to the peritoneum. If the tumor is a large one, which is rare in the early stage of the disease, he may now see some evidences of œdema of the extra-peritoneal tissue, or even find the matter has broken down this membrane and has invaded the abdominal walls, but usually nothing is visible till the peritoneum is cut through, when one of three conditions may present itself.

First. A mass of œdematous, opalescent exudation of varying thickness, sometimes half an inch or more in depth, may be observed. On cutting through this he may come down into an abscess cavity large or small. This condition is likely to be found in the more slowly progressing troubles of the vermiform appendix, and it particularly belongs to those cases in which there have been previous and not very far distant attacks of appendical inflammation.

Second. The parietal peritoneum may be found normal, or perhaps adherent to the adjacent coils of intestines by a few recent adhesions. On gently pushing through these latter, if such exist, a firmer resistance may be encountered, and on boring through this with the point of the finger the cavity of the abscess is opened. If the parietal peritoneum and the adjacent intestines should be apparently free from adhesions, and yet an abscess be recognized by a tumor, though at some distance from the surface, it can be opened, and entered in the same manner by the finger. When this form of a more deeply located abscess is observed, it is wiser freely to enlarge the incision in the parietal peritoneum and to push away the interposing intestines, until warned by adhesions that the abscess is being approached, when the free peritoneal cavity can in a quite perfect manner be protected from the irritation of the pus that is about to be evacuated, by first packing the cavity with sponges or iodoform gauze; after this the abscess may be opened. I may, however, here remark that the septic influence of such pus on the adjacent intestines, in the cases that have come under my own care or observation, has been entirely absent, and this is contrary to what has been theoretically stated by those who oppose an early operation for the relief of these abscesses.

Third. There may, finally, be found on the immediately presenting loops of intestine next to the parietal peritoneum (or it may be encountered in the region of the cæcum), pus in moderate quantity and not encysted, or purulent lymph smeared over the intestines. An exposure of the appendix, which is usually easily done in these cases, may show indubitably that it is the seat of the trouble, being either inflamed, perforated, or gangrenous; and the further exploration by means of a sponge on a long forceps carried into the pelvis or into the dorsal gutter of this side may reveal that we have to deal with a general suppurative peritonitis.

As a direction common to all of the above conditions save the last, it may be said that if the surgeon encounters a limited abscess and opens it, it is further treated simply by introducing a drainage tube, and possibly by a partial closure of the abdominal wound and the usual antiseptic dressings.

I have already stated the objections to washing out or freely exploring such cavities. I can also see only danger in all the attempts that have been made by some to search for and to remove either the concretion that has produced the perforation or the perforated appendix itself. If the appendix should, however, be exposed and be readily accessible, it is proper to tie it off by a stout silk ligature. No fear need be entertained of a permanent intestinal fistula in any form of abscess, even where its contents smell strongly of feces, or even where there is a more or less decided flow of the contents of the bowel from the cavity for some time after the operation.

Furthermore, while not in a position to make the statement with positiveness, I have been strongly impressed in my investigations by the fact of the rarity of recurrence of perityphlitic abscesses that have been relieved by operation and where no interference with the appendix had been resorted to. This seems to support the advice just given, not to strive too zealously to get away the appendix. It is reasonable to suppose that the cicatrization of the perforation, occurring, as it usually does, in the upper part of this tube, obliterates its lumen so as to form a permanent safeguard against a recurrence of the disease.

On General Suppurative Peritonitis.—As has been stated, an exploratory operation, conducted in the manner just described, may reveal that the peritonitis has invaded the peritoneal cavity to an extent much wider than the iliac fossa. This spreading inflammation shows itself in two forms, to which I am disposed to attach some clinical difference in importance. One, with the ordinary lymph exudation, with occasional small depots of matter, or with moderate layers of liquid pus bathing sundry sparse coils of intestines, with its focus of intensity in the right iliac fossa. This form is often associated with both completely and incompletely circumscribed abscesses. And in another form, where there is comparatively a scanty amount of plastic exudation,

and where the intestines are bathed over a great extent with a thin layer of pus, which, however, is but seldom encysted, and in which pus is found in considerable quantities in the pelvis or along the dorsal gutters.

This latter form is, to my mind, the most intense, most fulminating, and most septic form of the disease, and is frequently met without any attempt at a circumscribed abscess, or, if so associated, the latter is small and has early burst its barriers. Prior to operation this kind of peritonitis can sometimes be recognized by puncturing through the abdominal wall with a hypodermatic needle in other places than in the right iliac fossa, or by a hypogastric puncture made deep in the pelvis, the bladder being first emptied. Whether these differences in inflammatory action, the result of a perforation of the appendix, are due or not to the amount of fecal or gaseous extravasation that takes place, is somewhat difficult to determine, but the experiments of Pawlowsky[1] seem to support this view. This observer has found, experimentally, that in the peritonitis resulting from perforation of the intestine, a peculiar germ, called by him the bacillus peritonitidis, is usually found, and that cultures of this bacillus brought death, when injected in animals, in from twenty-four to seventy-two hours, with the production of a fibrinous, purulent peritonitis. Where the disease lingered a little longer the peritonitis was purely a suppurative one.

In 6 cases of suppurative peritonitis of a marked character, coming from a perforated appendix vermiformis, and not included in the 26 previously referred to, that have been treated by me by laparotomy, in all was the lumen of the appendix sufficiently large—up to its origin in the cæcum—to have permitted of a free escape of the irritating contents of the intestine. This patency of the appendix I cannot but think must have an influence on the severity of the disease. In health and in disease its lumen greatly varies. Kraft[2] has also suggested that differences of severity might be ascribed to variations in the mobility of the appendix; that, for instance, where it was short, as with a scant mesentery, or was confined by some previous adhesions, a more limited inflammation might be expected.

While some observers have advised for a recognized suppurative peritonitis that the treatment required should be carried out through the lateral exploratory incision, I have myself, in two instances where it was practised in this manner, found myself somewhat hampered by the limitations of this incision, and therefore prefer to make, in addition to the exploratory one, a median incision, believing that this more commanding section expedites the treatment and renders it more certain. The lateral incision can be subsequently utilized for drainage purposes and for the special treatment of the appendix itself.

The median incision is also to be advised from another standpoint which has lately come home to me. In two instances I have observed that though the sponge introduced in the pelvis drew out pus through the lateral exploratory incision, yet the further carrying out of the treatment of cleansing the abdomen, etc., showed that the general cavity had not been invaded throughout its whole extent until the surgical manipulations had been employed, and that, had a median incision been made, one might possibly have been able to recognize and evacuate these abscesses, of unusual size and with slight limiting adhesions, without exposing the patients either to the risk of infecting the only moderately damaged peritoneum above, or, what was more important, might have spared them the exhaustion consequent on the necessity of a prolonged toilet of the abdominal cavity. Hence, it has now become my rule, after the resort to the lateral exploratory incision has demonstrated that no collection of matter is here present, and that the symptoms there or elsewhere found point to a possible invasion of the general peritoneal cavity, to resort to a median incision opening into the cavity rather high up, and carefully to enlarge it downward as may be required. Such abscesses can sometimes be recognized and treated per rectum, which, therefore, should always be examined in a case of perityphlitis or any form of peritonitis.

If, after all, a veritable general suppurative peritonitis be encountered, we have one of the most discouraging lesions in the whole of surgery to treat. Whether we resort to the sponging out of the pelvic cavity or dorsal gutters, a very exhausting procedure, or whether this cleansing is effected by repeatedly filling the peritoneal cavity with boiled water, or with a solution of salicylic acid 1 : 1000, or other non-poisonous antiseptic solutions, or whether it be accomplished by the less irritating means of irrigation with one or two glass tubes carried down to the bottom of the abdominal cavity in various directions, according to Tait's suggestion, and however thoroughly, however quickly this end may be accomplished, and however satisfactorily we may place our drainage tubes, say one in the pelvis, one out through the lateral incision down to the stump left by the removed appendix, the difficulties of the case are but half encountered.

No delay need be made in this part of the operation, or, indeed, under any circumstances, by endeavoring, after cutting off the appendix, to cover the remaining end by peritoneum, as Treves has sug-

[1] Beiträge z. Aetiologie und Entstehungsweise der akuten Peritonitis. Centralblatt f. Chirurg., No. 48, 1887.

[2] Ueber die frühzeitige operative Behandlung der durch Perforation des Wurmfortsatzes hervorgerufenen Perityphlitis stercoralis. Samml. klin. Vorträge, No. 331.

gested. Surgical experience is sufficiently great, here as well as in the removal of the gall-bladder and in ovariotomy, to show that this is unnecessary. Granted that the patient's strength, already wasted by the disease, enables him to tide over the shock of an operation of this character, there remain after the closure of the wound dangers which thus far our surgical art has not yet learned to overcome.

Out of twenty-five cases of this description of general peritonitis arising from perforation of the appendix vermiformis, but one has, so far as I have been able to learn, been saved. Two doubtful cases[1] have been recently classed in this catalogue, but a closer reading of their histories seems to point more toward the spreading exudative form of peritonitis with a circumscribed abscess than to the true suppurative type; but even these should be considered as triumphs of surgery.

In my own six cases of laparotomy for this disease in its well-marked form, death has ensued in every instance, either from the shock of the operation, that is to say within twelve hours thereafter, or from the persistence of the symptom which exists nearly always before the operation—I mean fecal or fecaloid vomiting, the matters vomited being always of a yellowish or creamy-brown color, but not always having a fecal odor attached to them; a condition which, beginning as the ordinary green bilious vomiting, thence changing to the above character has been so frequently proved to me by autopsy in connection with intestinal stenosis where no peritonitis existed as to convince me that its significance is always that of obstruction, though it is true this obstruction may be caused by peritonitis. This obstructive symptom is due, as the interesting investigation of Malcolm[2] has shown, to paralysis of the muscular coat of the bowel occurring from the overstimulation of the nerve-plexus of Auerbach which supplies it. Operative procedures of themselves sometimes occasion this paralysis, but septic influences are the most potent causes.

Sometimes obstruction is produced by the pressure of the distended coils on an adjacent part of the bowel.[3] This has been found not rarely in post-mortem examinations. Irregular contractions of the bowel, due to septic irritation of the muscular coat, are also found. It is this absolute paralysis of the intestine which constitutes, in addition to the general poisoning of the system, the great danger in these cases. And while the success of the early use of purgatives in the lesser forms of obstruction after ordinary laparotomies has only confirmed Mr. Tait's eulogy of this method of treatment, yet in these marked septic forms of peritonitis his treatment utterly fails. It is the exception to succeed in bringing about purgation, use what you will, whether salines, mercurials, or the washing out of the stomach.

In the three of my cases wherein the duration of life after the operation was prolonged sufficiently to enable me to undertake the trial of every method to overcome the obstructive symptoms, nothing brought about a discharge from the bowel save in one instance, and in this to but a slight extent. Moreover, in one case, as a last resort, it seemed proper to me to open one angle of my abdominal wound and to draw out the first presenting distended loop of intestine, at that time shut off by adhesions from the general cavity, and open it. But a scanty amount of fluid feces came out of the artificial anus thus formed, and without any marked relief to the patient. Also in one of Duplay's cases a tube was introduced through the perforated appendix into the colon without any benefit resulting therefrom.

In the autopsy of all of these cases (and this remark is only of value in the three who lived beyond twenty-four hours) there was but very slight evidence of fresh peritonitis, yet the temperature had kept up so high throughout as to corroborate the belief that no matter how thoroughly one might wash or cleanse the peritoneum during the operation, much septic material must be left in the various patches of exudation or in the inaccessible nooks of this cavity, to perpetuate the infection raging in the general system.

I had been much struck with the remarkable results witnessed in the wards of Mr. Treves in the treatment of suppurating disease of the knee-joint, by continued aqueous irrigation for a period of nearly a month, with the effect of securing a perfectly movable articulation, and had determined, in the next case of suppurative peritonitis presenting itself to me, so to arrange an entering tube, lodged in the pelvis, and a smaller emergent one in the upper part of the abdominal cavity, as to conduct a continuous stream of boiled or salicylic water through these for a number of days, and thus to secure, at least for a moderate length of time, a hyperdistention of the cavity, and a thorough dilution of its poisonous contents.

This idea, I have already learned, has been put into effect by Penrose, of Philadelphia,[1] who used on one occasion two glass tubes placed in the pelvis, and one large tube running from the epigastrium to the lower angle of the abdominal incision. The irrigation was not, however, continuous, but the abdomen was flushed with warm water every two hours for twenty-four hours after the operation, with a successful issue to this case of suppurative

[1] Those reported by Drs. Sands and Jacobus.

[2] The Condition and Management of the Intestine after Abdominal Section, considered in the light of physiological facts, by John D. Malcolm. Med.-Chir. Trans., vol. 81, 1888.

[3] Verchére: Septicémie Intestino-Peritonéale. Revue de Chirurgie, July, 1888.

[1] Intestinal Obstruction in its Surgical Aspects. Journ. Amer. Med. Association, July 14, 1888.

peritonitis with gangrenous patches on the sigmoid flexure.

Greig Smith[1] and Wylie also announce that they have used this repeated peritoneal flushing with advantage. Clinically, however, it must be admitted that such hyperdistention of the peritoneal cavity and ablution of the intestines can be carried on but a short time, as experience with the ordinary drainage tube shows how rapidly the general cavity is shut off by adhesions.

In concluding these remarks it must be again placed prominently forward, that though laparotomy for general peritonitis following perforation of the appendix has had most discouraging results, yet that in nearly every case in which it has been so performed the disease had existed, on the average, nearly three days, the shortest time being thirty hours. Pawlowsky's experiments, and my own operations and those of others, tell us that the delay is an all-important fatal factor in these cases. Where the agonizing pain that ushers in often mild as well as severe cases does not yield to opium, and the vomiting does not cease, and particularly the temperature does not fall within twenty-four or, at the most, forty-eight hours, then promptness of surgical action is required. Much less time should be allowed if the pain spreads, and other symptoms aggravate in severity. The query is, whether the prospect of an early laparotomy is a better one than the chance of a limited abscess forming. This latter is not a large one. My own collection of autopsies shows that a patient has about twenty-five chances in a hundred in his favor.

I venture, therefore, in terminating this paper, to present the following conclusions, based on observations of 100 post-mortem examinations and from 32 personal operations for so-called perityphlitic abscesses:

I. That all such abscesses originate in the peritoneal cavity, and there develop to an appreciable size before invading extra-peritoneal tissues or viscera.

II. That as stercoral accumulations or cæcal perforations are so rarely met with as causes of perityphlitic tumor or abscess, they should not be considered from a clinical view in any given case.

III. That in an attack of perityphlitis originating, as it generally does, as a perforation, or as a gangrenous condition of the appendix vermiformis, all use of purgatives or enemata is in the beginning of a case to be avoided, and the immobilization of the patient is to be insisted on, and aided, if necessary, by anodynes.

IV. That if a tumor be found, it be opened by a lateral incision as soon as symptoms, constitutional or local, indicate the formation of pus.

V. That if symptoms indicating an increase of the local peritonitis, such as the persistence of vomiting, spreading pain, abdominal resistance, and temperature elevation, continue, with or without the formation of tumor, for a period of forty-eight hours, the danger of the disease is greater than the proposed lateral or median laparotomy, which should then be immediately resorted to. In many instances even a less time should be afforded the consideration of the disease before operating.

VI. If a general peritonitis be suspected, corroboration can often be obtained by abdominal aspiration with a fine needle employed in places other than in the right iliac fossa, and particularly by a deep, hypogastric puncture into the pelvis, the bladder being first emptied. However, if left in doubt, it is better to operate.

VII. [*Sub judice.*] That if general suppurative peritonitis be found at a laparotomy, lateral or median, avoid too much handling of the intestines, and trust to either temporary irrigation with large glass tubes (Tait's), or, more rationally, to permanent or repeated irrigation and fluid distention of the abdominal cavity, as advocated by Greig Smith and by Penrose.

VIII. [*Sub judice.*] To meet the obstruction symptoms due to septic paralysis of the bowels, which often persists after a laparotomy for suppurative peritonitis, saline purgatives and repeated washing out of the stomach should be resorted to, even though vomiting be present to a marked degree. Enterotomy may also, in exceptional cases, be entertained.

THE EFFICACY OF FILTERS AND OTHER MEANS EMPLOYED TO PURIFY DRINKING-WATER.

A Bacteriological Study.[1]

BY CHARLES G. CURRIER, M.D.,
OF NEW YORK.

(Concluded from page 431.)

ALLIED to the porous stone filters are those of porous porcelain prepared in this country. Porcelain baked at the same low temperature as the porous cups used in electric batteries is, in its efficacy, very much like the stone just described. Under a low pressure, water passing through this substance during one or two days can become completely sterilized, which is a result superior to that got from the stone filters. Before much water has passed, the bacteria make their way through and multiply somewhat on the passage. This material, as I have thus far found it, of American manufacture, is therefore imperfect, yet is superior to rebaked porcelain in the single important respect that it is not brittle, while the rebaked porcelain cylinders of the Chamberland-Pasteur filters are quite fragile.[1]

[1] It has for some time been known that fluids can be rendered germ-free for laboratory use by being passed through solidified plaster-of-Paris (best prepared with incorporation of asbestos.

Recognizing the defects of other substances, Pasteur and Chamberland[1] called attention to their filtering cylinders, in which the important element is unglazed, rebaked porcelain. Originally employed to facilitate "cold sterilization" of fluid culture media, the fact that water went through the porcelain without carrying any bacteria with it has caused attempts to popularize its use. Inasmuch as some bacteriologists on both sides of the Atlantic had reported that this filter prevented the passage of bacteria, I was careful to use only selected cylinders without flaws, and did not omit any precaution to prevent the introduction of contaminations.

The most satisfactory way of using this for testing was to employ the single porcelain cylinder, within the usual casing, attached to a hydrant system and with a pressure of water varying from six to fifteen pounds.[2] Even with the highest New York hydrant pressure the flow is only drop by drop. It can be used to siphon water out of a jar, and in this way it works nearly as rapidly as when attached to the hydrant in the basement of a house in the centre of this city. By a porcelain cross tube sold in Paris, two or more cylinders can be siphoning at the same time into the same tube. To avoid risk of contamination, I used for siphoning a single cylinder, to which a bent glass tube was attached by a tightly-fitting piece of rubber pipe, all parts having been sterilized as well as the water by which the flow of the siphon was started. I got germ-free results regularly by this means in seven trials with two cylinders used separately;[3] but, in order to insure this, all the precautions mentioned are necessary as, in the water siphoned in domestic use of these cylinders, bacteria of various sorts are found, yet they are possibly contaminations due to the inherent defects of all such joints as are used. So I have devoted more time to testing these when directly connecting with the hydrant, as very slight precautions are needed, in their use with faucets, to eliminate all chances of contamination.

My first thirteen trials of this filter used in this way were under less satisfactory conditions than the fourteenth and those following, as the former were in a laboratory where the available water came under not much more than twenty feet pressure from a tank, and I was not able so well to control the constancy of this pressure as I was during the later trials. My first sixteen tests of various ones of these cylinders gave sterile water. Then, attached to a basement faucet, with a direct flow from the hydrant under a pressure never exceeding fifteen pounds (except that on Sunday nights it was for a few hours three pounds higher), the filter, after several days of intermitting use, gave over 3500 bacteria in each cubic centimetre and all the water examined (two samples per day) for four days showed an increasing number of bacteria.[1]

On the third and fourth days after the first passage of bacteria through the porcelain wall of the cylinder, the number in each cubic centimetre varied above and below 400,000. The filter was then sterilized by steaming for five hours, as was also done between the second and third series of tests. These tests bore out the results of the former observation.

That these results show that average specimens of this substance have the inherent defect of all filtering material, though in a much less degree than all others, seems to me unquestionable. That the bacteria did not get through owing to some defect in the particular filters which I used is evident from the fact that the cylinders employed (and which were selected by me in Paris as perfect), through which the bacteria passed, are still free from any appearance of a flaw which could explain the passage of these micro-organisms. The same filter which (first of those used in my tests) allowed bacteria to pass through, has repeatedly filtered water free from all bacteria for a few days after each of the several sterilizations which it has since undergone.

In three following series of trials of this identical cylinder, bacteria have gone through its walls in from three to four days after each sterilization. They have also gone through a second perfect cylinder with which I experimented. That the bacteria were not introduced by careless manipulation is evident by reason of their number, and because of the fact that, after the filter was sterilized, they were found in each case at a particular phase of each series of tests with the intermittent pressure which only for a few hours once a week was as high as eighteen pounds, and was usually as low as eleven. At the beginning of each series of tests the filter was sterilized.

The bacteria were not splashed in from the sink below, for, in the first place, all splashing failed to carry in any as revealed by testing the water filtered

shreds). These filters, however, lack permanency and cause the objectionable sulphate of lime to be present in the filtrate

Chamberland: Comptes Rendus Hebd. (etc.) de la Société de Biologie, 1885, p. 117.

Immediately following this (*idem.*, p. 120) were reiterations of adverse criticisms by Galippe and Bourquelot.

[2] This highest pressure was only at night, and once on Sunday night the pressure for a short time was three pounds greater. During the daytime the pressure was rarely more than ten or eleven pounds, but occasionally the gauge vibrated a little higher on account of the concussion of the water while a neighboring pump was working. The pressure was tested by an expert, and was only half of that indicated on the French circular of the agents of this filter in Paris as yielding 200 litres (50 gallons) per day.

[3] One cylinder being used three times, and another four times, each being carefully sterilized before each trial.

[1] The varieties first passing through were:

1. Colonies liquefying gelatine, and composed of medium-sized very mobile bacilli.

2. Superficially-spreading colonies of short, mobile bacilli.

after such experimental attempts to throw water in, and none had ever multiplied inside or even remained there during my first thirteen tests, when there was much splashing in the common sink. During my later trials there was no chance of such contamination.

To answer fully in advance any such objection, I will state that after I got the enormous number of over 400,000 in each c. c. flowing through the porcelain, and had sterilized the cylinder, water was allowed to flow through it and plated, but was sterile in that no bacterial colonies developed. Then, while the filter was in action, I introduced, with a sterile needle (from below through the aperture into the inside of the cylinder), and, touching the needle to various parts of the surface, deposited over it peculiar bacteria from a pure culture derived this winter from the water of one of the northern lakes which I examined during my investigations as biologist for the Syracuse Water Commission. The colonies of this bacillus, when growing on gelatine plates, have a peculiar odor, a distinctive green color, and other characteristics which clearly differentiate them from any bacteria ever found in the Croton water. The water flowing out all the while, or rather dropping out, was, three minutes after the introduction of these, collected in sterilized test-tubes and was found to contain 175,000 of these peculiar bacilli in each c. c. After seventy-five minutes there were only 14 bacilli in each c. c. of the water then flowing through the porcelain and two hours later, and during the next day, there were no bacteria of any kind in the water which again later in the series showed that the Croton bacteria had passed through with it. This proves that the increase in the number of the bacteria was not after the water had passed through the substance of the filter.

These facts, together with the extreme fragility of this rebaked porcelain, and the exasperating slowness of the flow, which does not improve on long trial, have caused me to modify the recommendations which I gave among my colleagues and others after my first tests of these filters.

As regards rapidity of flow and non-fragility, a notable improvement over the cylinder form (which I have just spoken of) is afforded by a series of two or more flat plates of porcelain similarly prepared. In the Varrall-Brisse pattern these porcelain plates are backed by carbon plates of the same shape and size and the filter yields sterile water for a long time under gentle pressure, although I do not consider the carbon an advantage. The further such filters vary from the simplest type, the greater is the likelihood of the introduction of contaminating bacteria into the filtered water.[1]

Of the various forms of filters used upon faucets, I feel bound to warn against those rotating within an outer shell. Whether packed with charcoal, sand, or any other material, and even if the water go through the filtering mass and not around it, the filter has the great drawback of various irregularities and depressions on the interior which retain organic matter and allow bacteria, both harmful and harmless, to increase in it and maintain their vitality for a longer time than in ordinary filters. This conclusion I am led to by the results of various experiments and observations. In a recent epidemic in a large New England city this form of filter appeared to play an active part in continuing the infection, for cultures, in every respect like those of the germs of typhoid fever, were derived from several of these suspected filters by Dr. Prudden and others. I have found that the typhoid bacillus lives much longer in the sediment collected from filters than in pure water.[1] At its best, this filter cannot remove the bacteria from water, and they multiply in the charcoal or sand so that, even after several minutes of washing out by the stream flowing from the hydrant, the water coming through this filter may show several times as many as are in the water directly from the hydrant. To avoid waste of time in repetition, I will refer to the facts observed with the sand filter, as the mechanical action of the filtering mass is identical in both.

The sand filter, for attaching to faucets, is perhaps the simplest and most popular used. It consists of a cylinder of like breadth and length, being not quite three inches long. It screws by either end upon ordinary faucets, and its interior is filled with crushed silica or fine sand, kept in place by wire-gauze at either end. I have adapted several much larger without securing more satisfactory results. Taking a new one, sterilized throughout, allowing a fair stream of water to flow through it when attached to

[1] As out of twenty-seven kinds of filters that I have been able to test, this seems, on the whole, the best substance yet produced for the purpose, it is to be hoped that American ingenuity make further improvements upon the models now existing. The cost need not be great even if all be carefully tested before being sold, as suggested by Fol and Dunant (Rev. d'Hygiène, 21 mars, 1885, p. 183).

The "Pasteur Filter Co." requests me to state that it now furnishes a slightly different style of cylinder in which the porcelain is invariably of fine quality and claimed to be "germ-proof."

[1] I have removed the slimy sediment from the outside of a porcelain filter, and without sterilizing this, put it into sterile test-tubes, and then added water in which the germs of typhoid were found living. After these had stood together for four weeks, several plates of the water were prepared and, making several cultures from the various colonies which appeared like typhoid, a bacillus identical in all its features with that of typhoid was isolated, and considered as typhoid by those to whom it was shown. This is longer than I have been able to keep this bacillus alive in pure Croton which had been sterilized. All waters tested were in tubes of the same size and at the same temperature. In laboratory experiments we are not able to reproduce the conditions existing in the large bodies of water, where these harmful bacteria can probably live longer still under the evener temperature there prevailing.

a faucet and at the same time taking water directly from the same supply-pipe from the hydrant by means of another faucet by its side, and under the same conditions of pressure and outlet, except that there is no filter upon the second faucet, the water is seen to flow in a free stream nearly as large as from the unobstructed faucet, while the Pasteur filter, attached to the same supply-pipe and with the same pressure, allows the water to come at the rate of only a few drops each minute. Even with a gentle stream through the freshly sterilized sand filter, very few of the bacteria are arrested. With very fine sand in a cylinder holding three times as much as the ordinary one, and a very small stream flowing, I have observed more than fifty per cent. to be retained. This result is seen only in the first use of an absolutely sterilized filter.

Speaking of the tank variety of sand filters, it was shown that moistened sand favored the increase of bacteria brought into it by Croton water which had flowed through. In the sand or other granular contents of these filters attached to hydrants the same multiplication takes place when the water has for some time ceased flowing, and this increase is at a more rapid rate than in water standing in a clean vessel by the side of the filter. The first flow in the morning, for instance, after the filter has remained unused over night, shows a much larger number of bacteria than the hydrant water then contains. Even after the water has flowed for several minutes for the purpose of washing out the filter, the bacteria are in excess over the number in the original water. After such a filter has had the hydrant stream running through it long enough to wash out all the germs that have resulted from the increase (which complete cleansing is not always producible), the bacteria in the water may appear nearly the same in number as in the hydrant water, varying slightly either above or below. While such filters are worse than useless from a bacteriological point of view, they are good strainers when not clogged by too long use without cleansing. As strainers they are less troublesome than flannel bags (which are as safe as these sand filters for use with suspected water, provided that they are removed at least once a day to be disinfected by boiling). The act of reversing this popular sand filter does not cause the removal of the organic matter upon which the bacteria can be nourished. Only the loose outer portion is thereby removed. Such a sand filter is a safer strainer when never reversible and it should be cleansed at least once a day when needed at all.

Powdered magnesia and other granular substances used instead of sand in the style of filter just described, have no superiority over the easily cleansed sand.

Asbestos-board I have not been able to procure of sufficiently firm, strong, and fine surface to resist the passage of bacteria under any considerable pressure from the hydrant brought to bear upon such a surface. The quality of the surface seems the important point. To yield a flow of any degree of rapidity, this surface must be large and that creates a tendency to break and necessitates a bulky filter, which most people shun. Packed asbestos shreds allow a few bacteria to pass through when the sterilized filtering mass is so dense as to cause the flow to be very slow. In this substance I have, as already mentioned, not observed so marked multiplication of bacteria as in the sand, porous and other filters.

Although large bodies of sand fail to prevent the passage of bacteria with the water which percolates through, it is noticed that certain natural filters of this sort render water much freer from bacteria when the water has first to make its way through a layer of silt and minute particles which have been arrested by fine sand. It is from the application of this principle that the large filter-beds are built which purify the water distributed by hydrants throughout various cities. Taking as a model the very carefully managed filter-beds of Berlin, it is seen that above the base of the filtering tanks is a layer of a foot of stones, gradually becoming smaller in size toward the upper surface, upon which is coarse gravel to the height of a foot more, then upon this a little more than two feet of sand, which at the top is as fine as can be procured. When the filter-bed has been freshly cleaned, as is found necessary for it after being constantly used for a week or so (occasionally several weeks), purified water is slowly backed into the filtering-mass from below until this water, carrying up all the air with it, has reached the top of the upper layer. Then the ordinary river (or lake) water is made to flow very gently in, to the depth of one metre. This is then allowed to stand for at least twenty-four hours. The nitrogenous or other particles, confervoid vegetation, and whatever else the water contains as sediment, have then settled upon the upper portion of the fine sand without sinking deeper, and a delicate film is formed which, with careful inlet and gentle pressure (never to exceed two metres of water), retains nearly all the bacteria of the water supplied, and prevents their passage, provided that the flow through is very regular and slow (never more than three metres in a day). Nearly all this separation of the bacteria is produced by the sedimental matter retained on the surface of the sand, so that, when the filter slows from clogging, it is found that less than half an inch of the upper layer of sand need be removed.

From the statistics of Wolffhügel[1], and of Plagge and Proskauer,[2] we learn that the number of bac-

[1] G Wolffhügel: Arb. aus d. Gsdamt., ii. 1 und 2, p. 109

[2] Plagge u. Proskauer. Zeitschrift f. Hygiene, 1887. ii. p. 401.

teria, originally very large in the river Spree, is reduced to a very small percentage in the filtered water, oftentimes a fraction of one per cent. I may add that the organic constituents are also decidedly lessened, and that the oxidibility, as tested by the reduction of a standard solution of permanganate of potash, is seen to be regularly lowered one-fourth and often one-third of the amount shown prior to the filtering. The long arrays of figures given in the reports of the action of these filter-beds show that, with hardly an exception, the ammonia is constantly removed by the process.

In this country the filter-beds, all of which are built upon the same plan as those in Berlin, are less perfect in their action, as the people in charge do not devote sufficient care to sedimentation in the case of those which I am familiar with. Thus, a very carefully planned filter-bed, which filters river-water for one of our cities, allowed, at the time when I examined it, nearly half of the large number of bacteria in the water pumped from the river to pass through. This unsatisfactory result seemed to be due to the fact that too much water was required from the small filter-beds and hence not enough care could be bestowed upon the thoroughness of the filtration.

Of the various large filter systems which I have tested while they were in use in various manufactories and institutions, for which these filters were straining large quantities of water, the only kinds which reduced materially the number of bacteria as found in the hydrant-water were those in which, by the addition of a minute proportion of a suitable salt, usually alum (as approved by the general experience of years in many districts), the suspended particles with the organic matter are caused to settle more rapidly, and then these form a deposit upon very fine sand, through which water is forced. From several examinations of a filter of this type, which in every case rendered the water much freer from germs than the original (unfiltered) water, I once found the filtered water wholly sterile, while the (Brooklyn) hydrant water of the neighborhood at the same time showed 397 germs developing from each c. c. This particular filter was constructed on the principle of Prof. A. R. Leeds, who informs me that the alum was present in the proportion of only 1 part in 100,000 of water. I could not, by the ordinary tests, detect the presence of this salt, and such a small amount can cause no appreciable harm. The alum used is probably decomposed, and its elements taken up by the organic matter and bases present. As previously stated, the sterilization of the water is here caused by mechanical and not by chemical action. In my tests the typhoid bacillus of the first agar culture from a recent spleen was not destroyed by standing for forty-eight hours in a solution of ten times the strength of that employed in these filters, while many other bacteria were alive after standing for forty-eight hours in an alum solution of 1 part to 1000 of water, which sufficed to destroy the typhoid bacillus in that time.

In the present stage of chemical knowledge there seems no sufficient evidence that in water these micro-organisms evolve the organic alkaloids which are considered to be produced when harmful bacteria are introduced into the system and by their action there cause disease. What the exact nature of the volatile organic constituents carried over in distillation may be, and whether they be deleterious or not, rests for the science of the future to determine. The process of boiling previous to vaporization in the still must kill all harmful bacteria, and all other bacteria that I have ever encountered in the original hydrant water from which such water as the well-known "Hygeia" is prepared. The bacteria which I have found in specimens of this excellent distilled water that I examined must have been introduced from without after the water was condensed from the still and before the bottling process was completed, and in this I have never found any other than harmless varieties. Water condensed from various stills of approved patterns I have found sterile. The relatively large amount of free ammonia found in such distilled waters (it being several times greater than any detected in the Croton hydrant water) does not seem to me to be objectionable. The condensed steam produced in distilling, and which constitutes the Hygeia water, represents a much larger original amount of water than results after the process of vaporization and condensation is completed, and the ammonia may besides come from the air and from other sources.

To those who desire a water freer from alkaline earths than the ordinary "hard" water which they may have to drink, it should be mentioned that the process of heating, in the sterilization by boiling which I so urgently recommend when it is necessary to drink suspected water, drives off free carbonic acid and so causes the deposition as an insoluble sediment of the carbonate of lime and other objectionable salts which form the so-called "temporary hardness." The water is thus rendered "softer."

When boiling is resorted to because of actual infection of the water, it should be carefully done. It is best to have the water, perhaps after a preliminary boiling and straining, decanted into bottles, each holding say a quart, and these covered with a suitable glass cap or plugged with cotton or provided with a clean stopper loosely dropped in, and then the bottles placed in a kettle or cauldron in the absence of a steaming apparatus. This is heated and kept near the boiling point[1] for an hour. Then

[1] Although Miquel and others have called attention to micro-organisms retaining their vitality at a temperature above 71° C. (160° F.), these seem to have no harmful character. See Glo-

the whole is allowed to cool, and the bottles may be placed near ice; but into the water thus carefully prepared it is not advisable to put ordinary ice, for harmful bacteria may retain their vitality in ice longer than in water. Pure water loses all its excellence when unwholesome ice is melted in it. For those to whom the taste of boiled water is unpleasant, weak teas, wine, or other savor may be added to mask the absence of the more agreeable taste imparted by the process of aërification (which under ordinary conditions may itself be a means of adding bacteria to the water).[1]

There are ingenious hypotheses as to the utility of nitrifying bacteria in overwhelming other varieties and conjectures that, if recognized and planted upon filters, these nitrifying ones would safely destroy the pernicious ones; but among these theories I know of none to be seriously recommended. The recent results in America and various parts of Europe are so inconclusive and diverse that the brief limits and practical aim of this paper will hardly permit any further consideration of them.

Summary.—Boiling sterilizes water, and within thirty minutes will have killed harmful bacteria.

Drugs and other agents acting chemically, if used in amounts which are commonly safe, do not sterilize water.

The prolonged heat which water undergoes in the usual process of distillation destroys all germs which may be in the water undergoing the process.

Ordinary filters, even if satisfactory as strainers, fail to remove all bacteria from drinking-water. So far from lessening the number in the original water, the filtering substance may allow a more rapid multiplication than these microörganisms would ordinarily undergo in the unfiltered water on standing, and the germs of disease, even if held back by the filtering substance, may be harbored in all filters.

The finer the substance through which the water passes, and the lower the pressure, the more perfect is the action of the filter in holding back the bacteria.

Of all substances thus far furnished for domestic filters, porous rebaked porcelain, carefully selected, I have found to be the best. If thick and strong enough to allow the use of a large surface, and the substance remain perfect (without flaw or break), this may yield a fair flow of clear water, free from all bacteria; yet under our ordinary Croton pressure of one atmosphere or less, this yield is only in rapid drops, unless the apparatus be complex.

To insure the permanency of this action, the filter should be occasionally sterilized throughout, by steaming or by other means; for, under prolonged pressure, various kinds of bacteria can go through, and in the copious organic matter collected on the filter some harmful microörganisms can retain a high degree of vitality for weeks longer than I have ever found them to live in pure water.

Where filtering is really necessary, it is in general best for the community that it be done carefully on a large scale through sand-beds upon which a fine layer of organic and inorganic matter is expressly produced by sedimentation, because of its valuable action in holding back the great majority of the bacteria.

A bad water filtered is less desirable than a pure water in its natural state. When, therefore, filtration is employed because of real danger of infection, the filtered water should, as a rule, be furthermore boiled, as the entire absence of sediment and cloudiness does not insure that the bacteria of disease may not have made their way through the filter.

big (*Ztschr. für Hygiene*, iii., 2, pages 322 and 331). The spores of the "red potato bacillus," which he reports as very resistant even to steam heat, have never appeared in waters that I have seen; and the time limits for boiling which I have elsewhere given, after careful observation, hold true as regards all known disease-producing bacteria.

[1] Berckholtz (Arb. aus d. K. Gesundheitsamte, 1889, p. 14) (employing exsiccator and four days of agar culture, dried on silk thread) found that the cholera spirillum, contrary to earlier results, retained its vitality in air for over two weeks.

In connection with my experiments I have found the typhoid bacillus to live dried on the glass of a test-tube, for a week and longer. I have made no special attempt to determine how long it will live in a dry state

Tommasi-Crudeli, Dr. Bern. Schiavuzzi in Pola (Rendi Conti della R. Accademia dei Lincei, Dicembre, 1886) say with others that the malaria bacillus, which they, like Klebs, found in soil and air, may be carried by and live in water. The same is true of many other bacteria introduced into water.

A CASE OF ANTIPYRIN POISONING.

By WILLIAM PERRY NORTHRUP, M.D.,
of New York.

The new drug, so efficient in relieving headaches, is, at present, so much used and so little suspected of danger, that it seems desirable to communicate a recent unpleasant experience. In speaking with different practitioners and neurologists, I learn that many times forty-five grains of antipyrin are given at one dose to an adult, and twenty-five to a child above five years of age, and they all add, "No drug is more satisfactory in its results."

The patient was Mrs. L., aged forty-four years, married, mother of three children. She had been subject to headaches (hemicrania) since childhood, but the attacks had been more severe and frequent since the birth of twins, after which she was sick in bed seven months, and, as she says "her nerves were completely upset—and her whole system." During convalescence, the patient used her eyes excessively, reading, doing fancy work, etc.

Since the twin birth, four years ago, she has been exceedingly nervous, and, as she adds, "nervous by spells," and "extremely irritable," with occasional numbness of the extremities and "lump" in her throat. At two different times in her life she

has passed over a year without an attack of headache. Immediately before the lapse of the second year she had suffered from rheumatism, and taken for its relief "salicylate." She believed the remedy had been the cure of the headaches, as well as her lameness. She has, however, since tried the remedy, and come to a contradictory conclusion.

With the two exceptions above referred to, she has usually had a headache every three or four weeks.

She has observed that over-fatigue and excitement are sure to be followed by her customary attack; also that overheating or chilling of the body provoked them, and that they came at longer intervals in summer than in cold weather. During the fall months of 1887, the intervals became shorter. Occasionally two attacks came within a period of ten days, and during the prostration of one of these quick recurring attacks I made my first observations on the case.

The patient, with the headache, lay with her eyes closed, raising her lids reluctantly and with effort when spoken to, answering questions in monosyllables, and as though irritated at the disturbance. Her face at times pale, again moderately flushed on the cheeks and pale about the lips, wore an expression speaking for itself;—"want to be left alone." Pulse was full, slow, and regular. Pupils normal in size, equal, and reacting promptly.

The headache was limited to the left hemicranium.

No remedy was administered at this time, as the attack was already beginning to wear off.

During the succeeding interval of relief, while the patient was in her best possible condition of general health, she was put to bed, and examined carefully —lungs, heart, liver, abdomen, uterus, and ovaries, condition of arteries, general circulation, accumulation of adipose, etc. Nothing was found abnormal. The patient was well nourished, free from disease, from malpositions, and from localized tenderness. She was large of frame, well proportioned, giving the impression of one with strong, enduring physique.

Examination of urine was negative—reaction, specific gravity, color, odor, and quantity; examinations for albumin and sugar bore testimony that the kidneys were doing their work perfectly. Ophthalmoscopic examination showed normal disks, vessels, and retinæ.

Was the headache, then, due to error of refraction? The eyes were examined under atropine, with test lenses, and the result was the patient was fitted with glasses for moderate hypermetropia (1.25 spherical) and instructed to wear them three weeks during waking hours. They made the vision clearer, and the head less confused while shopping and while upon the streets, but did not ward off the headaches. To remove the cause then, seemed impossible.

There yet remained the new drug, the magic remedy, "the most satisfactory drug that I know of," says one; "that I prescribe with the utmost confidence," says another. "I do not hesitate to send it to a patient at a distance, whatever the cause of the headache."

Antipyrin in fifteen grain capsules was ordered and carefully written directions were left against the time of the next attack. The patient was instructed when she felt the headache coming to go to bed, take one capsule and with it a tablespoonful of whiskey with an equal volume of water.

It happened after the usual short interval that the patient awoke in the morning with a headache of the customary kind, and without rising from her bed called for a capsule. The directions as to the whiskey were mistaken, and she took whiskey and water together to the amount of a tablespoonful. She took then fifteen grains of antipyrin with a half tablespoonful of whiskey upon an empty stomach. She felt no apprehension, no nervousness on taking the remedy; but took it rather with confidence that it would help her if not wholly relieve her.

As soon as she had taken the dose she felt "queer," that "the medicine was going all through" her, was mounting to her head; she had sense of "smelling pepper," and she began to sneeze—sneezed fully a dozen times in rapid succession. This was followed by an urgent desire to defecate: she arose from her bed to get to the commode and fell heavily upon the floor, unconscious. The next remembrance was of a sharp pain from a hypodermatic injection of whiskey in her wrist and of some one bending over her urging her to drink from a glass.

The patient lived but two blocks from my office and I was not long in getting to her in answer to an urgent summons. I found her lying on the bed, her eyes closed, her countenance pale leaden, her "jaw dropped"—in a condition of extreme general relaxation. There was no pulse at the wrist, no sensitiveness of conjunctiva, and no amount of irritation aroused her. I immediately injected twenty minims of whiskey into the first available place and shortly repeated it. The second injection caused her to move her hand to avoid the pain. In a few moments more she opened her eyes with a wild staring look and presently began to vomit frothy mucus. This "dry" retching continued more than an hour, at the end of which time the patient was nearly exhausted though clear in her mind. Her headache was not relieved.

For a week she kept close to her room feeling that for some reason the medicine had upset her digestion and that her headache, though but little prolonged, had been more than usually agonizing.

At the end of a month my patient was quite recovered from her treatment and was again suffering as usual from her periodic visitant. During this time she heard of numerous friends who had been relieved by the remedy—many ladies of her church who carried antipyrin in their purses and during the long prayer, if headache threatened, slipped a capsule or powder or tablet into their mouths and the attacks did not come on. Even after her former experience, though I suspect she never fully realized how the antipyrin had affected her, she consented to try the remedy in one-third the previous dose I took the precaution to get the medicine from a reliable down-town drug firm and directed that the tablet of five grains of antipyrin be taken on a full stomach and *with* a tablespoonful of whiskey with water.

At the first symptoms of her next headache the patient took her capsule and whiskey as directed and only communicated the fact when she began again to "feel queer."

When the sister of the patient learned that the remedy had been taken, she hastened for me and I arrived at the side of the victim of headaches within a few moments.

She was lying on a sofa with her head raised. her face this time flushed deep crimson, her neck, wrists, and hands covered with urticaria, tearing the clothing from her neck and chest, sighing and gasping for breath with a worried and anxious counten ance —comparable only to the severe dyspnœa of Bright's disease.

The pulse at the wrist was rhythmic, moderately full, but without good tension. The urticaria developed its characteristic wheals rapidly over all the limbs of the patient, the irritation tormenting her and adding to the already existing extreme restlessness. After an hour the severity of the symptoms began to subside.

She has since continued to have periodic headaches. Her general health is good and she wears constantly the glasses fitted during the course of treatment.

To test the quality of the antipyrin used in the first dose, I gave the remaining capsule of fifteen grains to Dr. T. Halstead Myers, who tried it on an appropriate case in his dispensary practice. He reported its action as like that of good antipyrin. The second dose of five grains came from Frazer & Co., New York.

Briefly to recapitulate:

Fifteen grains of antipyrin caused in an hysterical woman—

Sneezing.
Evacuation of the bowels.

MEDICAL PROGRESS.

The Use of Glycerine Enemata and Suppositories.—Dr. Alex. S. Polübinsky, of St Petersburg, publishes in the *Vratch*, Nos. 1, 3, and 4, 1889, an ably written and very instructive paper on the treatment of constipation of various forms by means of glycerine, administered in the shape of either enemata or suppositories. The paper is based on fifty cases from Prof. V. A. Manasseïn's clinic, of which in forty glycerine enemata and in ten Boas' suppositories were employed. As regards the quantity of glycerine used for an enema, in one case 1 gramme was injected; in nineteen cases, 2 grammes; in thirteen, 3; and in seven, 4. The suppositories contained invariably 2 grammes of the drug, the constituent being either gelatine or cacao butter. Forty-five patients were men, aged from twelve to fifty-five, and five women of from ten to forty. The following brief summary deserves to be placed before our readers.

A. *Results of clinical experiments.*—1. In 23 cases (46 per cent.) the administration of glycerine was followed by abundant motions; in 19 (38 per cent.), by scanty stools; and in 8 (16 per cent.), no action of the bowels took place. 2. The first group includes: *a*, such cases where the presence of fecal masses in the S. Romanum could be ascertained both by palpation and percussion; and *b*, such ones where the fecal accumulation could be elicited only by percussion. In the former subdivision the stools passed were solid and normally shaped; in the other they were rather loose (gruel-like). The first "call" was felt by the patient usually in one or two minutes to increase gradually in its intensity, and to be followed by a motion in three, four, or five minutes. The action was not attended or followed by any unpleasant sensations, except one case, where a rather vivid local burning was experienced by the patient for about fifteen minutes. A controlling enema, made of two and a half or three tumblerfuls of water, and administered after defecation, gave negative results (that is, the water returned unchanged) in 19 cases, while in 4 the fluid was found to be intensely stained with fecal matter. In one of the former 19 cases, however, a subsequent administration of castor-oil (℥j) was followed by a rather abundant stool.

3. The second group includes: *a*, such cases (6) where an ordinary enema, administered subsequently, did not bring about any action of the intestines; palpation detected fecal accumulation only in the sigmoid bowel, the cæcum being empty; *b*, such cases (9) where a glycerine enema produced only scanty stools, but a subsequent ordinary enema was followed by a free discharge; the examination proved that both the sigmoid bowel and cæcum (in other words, the whole large bowel) contained solid or loose fecal masses; *c*, such cases (4) where an after-glycerine aqueous enema remained inactive, but a dose of castor-oil caused abundant motions. The examination gave the same results as in the preceding subdivision, the cases concerning constipation of two or three days' standing. 4. The third group refers to such cases where glycerine gave rise solely to fleeting "calls," but otherwise remained quite inert, stools following a subsequent administration of ordinary enemata or castor-oil. 5. In the shape of suppositories, glycerine acts somewhat more slowly than when injected into the rectum, stools taking place in ten, fifteen, or eighteen minutes, which depends simply upon the circumstance that gelatine or cacao butter require a certain time for their liquefaction. 6. The "calls" induced by glycerine are short-lasting, and when the patient postpones or inhibits his defecation beyond the time indicated above, it may sometimes happen that no stool takes place at all.

B. *Theory of the action of glycerine.*—1. The eccoprotic action of the drug cannot possibly be attributed to anything like its softening or liquefying fecal masses, since (*a*) water, milk, olive-oil, and other fluids, when injected into the rectum in similarly small quantities (6 grammes or so), fail to excite any motions; (*b*) when injected in such trifling doses, glycerine is rapidly absorbed by the mucous membrane; (*c*) stools occurring after glycerine enemata are usually solid and sausage-shaped—

that is, show no signs of liquefaction; (*d*) neither are the masses covered with any watery or slimy layer; (*e*) stools take place within a short time after the administration of glycerine, while the liquefaction process should necessarily require a comparatively long interval. 2. Glycerine undoubtedly causes a local irritation (probably congestion) of the rectal mucous membrane, since (*a*) all patients experience a sensation of warmth or some burning in the rectum; (*b*) there is observed a slight rise of the rectal temperature after the enemata; and (*c*) on a digital exploration during "calls" there are detected fairly strong contractions in the upper portion of the rectum. The drug, however, does not increase the secretion of the rectal mucous membrane. 3. The irritation lasts until there is a complete absorption of glycerine. Possessing a great absorbability, the substance very rapidly penetrates into the (very rich) lymphatic vessels of the rectum, and, having disappeared from the latter, ceases to act. Hence it is unable to establish any considerable peristaltic action of the bowel lying higher up from the sigmoid intestine.

C. *General conclusions.*—1. The best results are obtained from glycerine in cases of fecal accumulation in the rectum and S. Romanum. 2. In cases of fecal stagnation occurring higher up (typhlitis, general intestinal catarrh, etc.) the drug is altogether useless. 3. Glycerine enemata or suppositories are indicated especially (*a*) as a means for "training" the rectum—that is, for exciting regular rectal "calls"—in cases of habitual constipation; (*b*) in cases of constipation caused by fecal accumulation in the large bowel, and depending upon an atonic state of the intestinal muscular coat, as occurring most commonly in women after parturition. Since intestinal atony in such patients is usually accompanied by a similar state of the abdominal press, a systematic employment of glycerine enemata must be obviously supplemented by daily abdominal gymnastics and massage, faradization of the abdominal muscles, and intra-rectal galvanization; (*c*) in such cases where the rectum and sigmoid bowel are mechanically compressed by pelvic tumors (including early pregnancy); (*d*) in retro-version of the uterus associated with pressure on the rectum; (*e*) in children suffering from scrofula of a torpid variety; (*f*) in such persons who experience difficulty and pain on defecation because of their feces being very hard, and who accordingly often abstain from stools. Here glycerine proves useful mainly as a local lubricant. 4. On the whole, glycerine enemata should be preferred to suppositories, since the latter (*a*) are more expensive; (*b*) their use is rather uncleanly (they easily melt in the hands, etc.); (*c*) their introduction into the rectum by a finger represents a by far more unpleasant procedure than an injection by means of a syringe. 5. In one group of cases, however, suppositories are to be preferred to enemata. It is the group mentioned (sub. 3. *f*) where a relatively slow action is desirable, and where the lubricant effects of glycerine are intensified by those of cacao butter.—*London Med. Recorder*, March 20, 1889.

Tracheotomy in Chronic Diseases of the Larynx.—DR. LENNOX BROWNE concludes a paper on the relative merits of early and late tracheotomy in chronic disease of the larynx, with the following *résumé*:

1. Early tracheotomy, with retention of the tube, is advocated in chronic sub-glottic laryngitis and in perichondritis, causing sub-glottic stenosis.

2. Tracheotomy, either early or late, is not advocated in tuberculous laryngitis.

3. It is but rarely necessary in lupus.

4. It is to be performed in œdema, occurring during the course of a syphilitic laryngitis, only after patient treatment has failed; and when performed for such a condition there is a fair chance that the tube may after a time be dispensed with.

Tracheotomy is preferable to attempts at dilatation in the case of syphilitic stenoses, and the tube has generally to be retained for life. Not infrequently the operation fails on account of inability to reach the seat of stricture.

5. The operation may be necessary in benign growths of the larynx, and, when indicated, is better performed early.

6. Early tracheotomy is strongly advocated in malignant disease of the larynx as the safest and surest means of prolonging comfortable life, and in this respect is superior to attempts at radical extirpation.

7. Tracheotomy is necessary in cases of bilateral paralysis of abduction, and should not be delayed if treatment fails to arrest the progress of the disease. It is seldom successful in cases of dyspnœa caused by pressure low down in the trachea.—*Journal of Laryngology and Rhinology*, April, 1889.

To Remove Summer Freckles.—

℞.—White precipitate, Subnitrate of bismuth } āā 4 parts.
Glycerite of starch . . . 15 parts.—M.

Every second day apply a coating of this preparation to the freckles.

Washing the affected parts with the following lotion mornings and evenings will also suffice to remove the freckles.

℞.—Sulpho-carbolate of zinc . . 4 parts.
Glycerine . . . . . 60 "
Alcohol . . . . . 30 "
Orange-flower water . . . 45 "
Rose water . . . . . 250 " —M.

—*L'Union Médicale*, March 23, 1889.

Tuberculosis of the Peritoneum.—From material consisting of twenty-five fatal cases of tubercle in which the peritoneum was either primarily affected, or in which it had been affected for a prolonged period, DR. HEINTZE deduces some interesting facts which he publishes in the form of an inaugural dissertation. All the cases occurred in the Breslau clinic, and necropsies were made in every instance, so that there was no doubt about the diagnosis.

He divides the cases into three groups: 1. Those where there was a copious fluid effusion. Here the clinical symptoms bore considerable resemblance to those met with in cases of ascites from congestion. From this condition they were distinguishable by the very large amount of albumin contained in the fluid drawn off on tapping. No tubercle bacilli, however, seem to have been found. After the distention had been relieved by the removal of the fluid, the thickened peritoneum could frequently be felt, and peritoneal friction could be de-

tected. These effusion cases formed the most numerous of the three groups. 2. The plastic form, producing a coating of tumor-like bodies. The pseudo-tumors formed by the exuded plastic matter could generally be distinguished from real tumors by the ill-defined character of their edges. This group comprised nine of the twenty-five cases, and in five of them there were tumors of considerable size. In these plastic inflammations there is generally a good deal more pain than where there is much fluid effusion; there is a tendency, too, to the formation of kinks in the gut and bands, which cause obstruction, so that fecal accumulations and ileus are not uncommon. 3. The latent form, where there is neither any great amount of effusion nor much plastic exudation. These are the cases which used to be classed as tuberculosis of the peritoneum, in contra-distinction to those in which the inflammatory symptoms were more prominent, which were denominated tubercular peritonitis—a distinction which Dr. Heintze thinks is unsatisfactory.

One remarkable point is mentioned in the dissertation—viz., the frequency with which tubercular disease of the peritoneum is associated with cirrhosis of the liver. This was found in seven of the twenty-five cases. Pleurisy was found twenty times, and signs of scurvy twice. In many cases there were long remissions, so the prognosis is not necessarily quite so grave as it is usually supposed to be. The patients died mostly from general tuberculosis, very rarely from perforating peritonitis or from tubercular peritonitis. Most of the cases occurred in the male sex, frequently amongst men addicted to drink. In three instances an injury to the abdomen had preceded the commencement of the symptoms.

As to operative measures, the only good that can usually be done is to empty the peritoneal cavity, so as to free the vessels from the pressure of the ascitic fluid; paracentesis only accomplishes this imperfectly. In the plastic form, operative measures are, as a rule, useless, it being impossible to remove all the diseased matter, as can be done in tubercular disease of bones or joints; still there are circumstances under which an operation may be imperatively called for—as, for example, where ileus is produced by the formation of constricting bands. Dr. Heintze does not think any advantage is to be expected from opening the abdomen and dusting the viscera with iodoform.—*Lancet*, April 6, 1889.

Antiseptic Midwifery at Liege.—In a paper read before the Liège Medical Society, by Dr. Fraipont, the method adopted at the obstetrical clinic there for rendering labor aseptic is described. The plan is based upon the researches and experience of Döderlein, and is very similar to that employed at the Leipsic clinic, where it is said that since it was commenced the number of absolutely normal puerperal periods has increased as much as eighteen per cent. In Liège every woman is given, on admission, a general bath, and minute precautions are taken to insure cleanliness. During labor the vagina is irrigated each time that an examination is made, by means of a three per cent. solution of creolin, which is injected through a glass tube introduced together with the index finger, which is made to reach as far back as the cervix. The labia are then occluded, so that the fluid may distend the vagina and obliterate all the rugæ, and reach even into the interior of the os, detaching and washing away the mucus accumulated there. From one to two quarts of the solution is used for each irrigation. Immediately after the placenta is detached, another irrigation is administered, which is repeated regularly during the first few days of the puerperal period. It is necessary to say that no lard is ever used, a substitute being found in a saponaceous preparation which is known under the name of "molline," and which, while acting as a detergent, is freely soluble in water.

Dr. Fraipont is much pleased with creolin for obstetrical purposes, considering it superior to the more generally used antiseptics. One advantage he mentions, which does not seem to have attracted attention generally, is, that it makes the mucous membrane soft and supple, giving it the feeling of having been oiled. When used in gynecological operations, where it is necessary to obtain a good view of the parts, it has, it is true, the disadvantage of obscuring the lesion with a milky fluid. This inconvenience is, of course, not felt in midwifery. In Dr. Fraipont's opinion, creolin ought to be given to midwives instead of such a powerful and dangerous antiseptic as corrosive sublimate, which, it is to be feared, they sometimes use with more zeal than discretion.—*Lancet*, April 6, 1889.

Absolute Rest in the Treatment of Tetanus.—Dr. E. de Renzi (*Rivista Clinica e Terapeutica*, January, 1889) states that since the year 1882, when he first tried this method, he has treated six cases of tetanus, five of which recovered. The following are the author's rules for this treatment:

1. The patient, whose ears are closed with cotton or wax, must remain in a perfectly dark and noiseless room, and should be told that recovery depends upon his keeping perfectly quiet.

2. Carpets should be laid in the sick-chamber and adjoining halls and rooms, in order to deaden all footsteps.

3. The patient's room should only be opened every four hours, and then with the greatest care. All food should be in the liquid form, such as milk, eggs (beaten), soups, wine and water, etc., and should be brought to the bedside in a cup.

4. One should enter the sick room with a covered light, being rather guided by the patient's moans than by one's sight.

5. If the patient be constipated, neither laxatives nor enema should be administered; nothing whatsoever is to disturb the patient's rest.

6. If the pains are intense, ergot and powdered belladonna may be resorted to.—*Bulletin gén. de Thérapeutique*, March 30, 1889.

Treatment of Eczema.—The *Revue gén. de Clin. et de Thérap.* of March 28th gives the following formulas for this affection:

Dr. Unna recommends for pustular eczema:

℞.—Oxide of zinc, Gelatin } āā 15 parts.
Glycerine . . . . 25 "
Water . . . . . 45 " —M.

Heat slightly, and apply with a camel's-hair brush.

Dr. Veiel, of Canstatt, recommends the following for pruritus:

℞.—Powdered starch . . . 98 parts.
Powdered camphor . . 2 " —M.

In the squamous stage of certain chronic eczemas the following is recommended:

℞.—Tar . . . . . 1 part.
Alcohol . . . . . 3 parts.—M.

Large Vesicular Calculus in a Child.—M. DURET, in the *Journal des Sciences méd. de Lille*, records the following remarkable case of vesical calculus in a male child of six years. The symptoms of stone had existed for two or three years. When the sound was introduced by the author into the urethra it impinged almost at once upon an enormous stone. There was, practically speaking, no vesical cavity, the mucous wall was in contact throughout with the calculus, and the urine escaped drop by drop continuously. Examination by the rectum revealed a large and hard tumor behind the pubes, which was formed by the bladder containing the stone. The urine was albuminous. The bladder was opened by the suprapubic method, but after this had been done it was found impossible to extract the calculus, owing to the firm way which the bladder had contracted upon the concretion. The finger of an assistant having been passed into the rectum, the bladder was raised *en masse*, and thrust forward; the stone was then broken up with a chisel and mallet, and the fragments removed. A drainage tube was fixed in the wound, no suture being placed in the bladder wall. The calculus weighed sixty grammes, and was composed of an oxalate of lime nucleus and phosphates. —*Medical Press*, April 3, 1889.

The Microbes of the Stomach.—DR. ABELOUS, at a meeting of the Academy of Sciences, stated that he had isolated from the products of washings from his own stomach, while fasting, sixteen species of microbes, of which he has studied the morphological characters, as well as their action upon alimentary substances (food-stuffs).

Of these sixteen species, seven are known: the sarcina ventriculi; the bacillus pyocyaneus; the bacterium lactis aërogenes; the bacillus subtilis; the bacillus mycoïdes; the bacillus amylobacter, and the vibrio rugula; of the nine remaining undescribed, one was a coccus, and eight were bacilli.

All of these microbes resist the action of artificial hydrochloric acid (1.7 parts of HCl to 100 parts of water) for a lapse of time much longer than the duration of stomachal digestion; especially is this the case when the cultures are rich in spores.

The following are the general results of the action of these microbes on alimentary substances (each species having an action more or less energetic): Ten attack albumin; twelve fibrin; nine gluten; ten transform, more or less completely, lactose into lactic acid; eight have a converting action on cane-sugar; eleven help, more or less, toward the formation of alcohol from glucose; thirteen assist the formation of glucose from starch.

The most remarkable results, however, are obtained from the combined action of all these microbes, at the same time, upon each alimentary substance. Under these conditions (especially when some chalk is added) one will observe a very rapid and very energetic decomposition with liberation of gas and the formation of such products as leucin, tyrosin, indol, skatol, and certain fatty acids and ammoniacal compounds. Considerable quantities of alimentary substances can be thus decomposed in a very short time.—*Revue de Thérap.*, April 1, 1889.

Carbolic Acid and Iodine in Whooping-cough.—DR. ROTHE, having met with some unfortunate cases of whooping-cough treated with antipyrin, turned his attention to a combination of iodine with carbolic acid in the treatment of this affection, and with this combination he has obtained excellent results. He has, he says, treated hundreds of cases, and cannot remember one in which the affection lasted longer than four weeks, besides which no fatal case occurred. The mixture he employs is as follows: acid. carbol., 15 gr.; sp. vin., 15 gr.; tinct. iod., 10 gtt.; tinct. bellad., 30 gr.; aq. menth. pip., 2 oz.; syr. opiat., 150 gr. A teaspoonful of this is given to children over two years of age every two hours. When this treatment was carried out from the commencement of the complaint the severity was never great, and even when it was only begun in cases that had been going on for six or seven weeks it soon cut them short.—*Lancet*, April 6, 1889.

Local Antiseptic Treatment of Erysipelas.—DR. NUSSBAUM (*Gazette Hebdomadaire*, March 29, 1889) replaces antiseptic subcutaneous injections for erysipelas by the following treatment:

1. Anoint the erysipelatous surface with the following ointment:

℞.—Ichthyol } . . . āā 15 parts.
Lanoline }

2. Immediately after having applied the above, envelop the affected portion with salicylated cotton.

This mode of treatment arrests the progress of erysipelas and diminishes the pain and the cutaneous inflammation in the space of from a few hours to three days.

Stimulating Liniment.—

℞.—Phosphorized oil . . 50 parts.
Chloroform }
Tincture of nux vomica } āā 10 parts.—M.

Rub the paralyzed members three times daily for five minutes with a flannel saturated with this mixture. After which envelop them in salicylated cotton.—*L'Union Médicale*, March 24, 1889.

Injections of Pilocarpine for Traumatic Tetanus.—DR. LUIGI CASATI reports having used pilocarpine injections with success in three cases. The results obtained from the author's experiments upon animals are, according to the *Deutsch. med. Ztg.*, as follows: Of 9 tetanized rabbits treated with pilocarpine 7 recovered and 2 died, whereas of those not so treated, all died as soon as the first symptoms of tetanus manifested themselves. Recovery is generally rapid, but after the symptoms of tetanus have disappeared they always recur a second time, and end either in complete recovery or death. Several hours after the injection a distinct division of the symptoms takes place. Trismus is the last symptom to disappear. The tetanized animals support doses of pilocarpine which, under normal circumstances, would prove fatal. Pilocarpine does not interfere with the development of the tetanus bacillus; should one inject Brieger's ptomaine in conjunction with pilocarpine, the rabbits will show no symptoms of ptomaine poisoning. but only the curative action of pilocarpine.—*Wiener med. Presse*, March 17, 1889.

SATURDAY, APRIL 27, 1889.

THE EFFICIENCY OF WATER FILTERS.

IT is well known that drinking-water may be the carrier of the germs of disease, and also be rendered otherwise unwholesome by the admixture of foreign substances both organic and inorganic. It is also a fact that drinking-water supplied to cities is often below the proper standard of purity, and in some instances positively bad. The failure of city corporations to supply water of good, wholesome quality, or at least of the appearance of such, has made it necessary for individuals to resort to means of supplying the deficiency. The expedients adopted for this purpose are mainly boiling and the various methods of filtration.

Domestic filtration is commonly employed to strain out suspended matter, and thus clarify the water. A more important object is the removal of bacteria. The efficiency of the various kinds of filters in the market in removing suspended particles is easily tested, but the determination of the efficacy of different filtering materials in removing microörganisms requires skilful manipulation in the biological laboratory. Chemistry failed to furnish the desired proof, and no means was available until the culture process was introduced. The application of this test has led to important discoveries, which have exposed the imperfections of filters usually selected for household use, and stimulated the search for materials better adapted to meet the newly imposed and most essential requirements of the process of filtration.

In an elaborate paper on the efficacy of filters, and other means employed to purify drinking-water, read before the Section of Public Health of the New York Academy of Medicine, on April 5th, and presented in the last and present issues of THE NEWS, DR. CURRIER has given the results of carefully conducted experiments, which show how little dependence can be placed on the usual methods of domestic filtration in removing infective matter from water. He shows that domestic filtration, as commonly practised, is little else than a process of straining, which clarifies the water but fails to remove bacteria. In fact, old filters, constructed of improper materials, and even sterilized filters of the best forms, after a comparatively short time, furnish water with a larger percentage of bacteria than that contained in the water before filtration. This result is due to the filtering materials, as charcoal, sand, and even porous stone and porcelain, becoming charged with microbes, and forming a suitable nidus for the development of these minute forms of life.

There is a limit to the purifying powers of even the best constructed filters. Their action, at best, is but temporary. The materials should, therefore, be frequently renewed, and porcelain and stone should be sterilized by heat, if the function of purification is to be maintained.

Dr. Currier's conclusions, based upon very elaborate experiments, are, briefly: That boiling for thirty minutes will destroy harmful bacteria; that chemical agents are useless for sterilizing drinking-water; that ordinary filters do not remove all bacteria from drinking-water; that filters of porous rebaked porcelain are the best, but to insure permanency of action they should be occasionally sterilized throughout by steaming, or other means. When filtration is necessary, it should be conducted carefully on a large scale through sand-beds upon which there is a fine layer of organic and inorganic matter expressly produced by sedimentation. When domestic filtration is employed, on account of danger of infection, the water should, as a rule, be furthermore boiled.

TREATMENT OF ACUTE INTESTINAL OBSTRUCTION.

The treatment of abdominal surgical affections has of late enormously outdistanced their diagnosis. Likewise it is true that all cases which finally come to the knife would present infinitely more recoveries could their exact existing condition and subsequent

course be recognized from the onset. So also exploratory incision of the peritoneum in the hands of competent men has come to be intrinsically so safe a procedure that, considering the ulterior consequences of an expectant course, early resort to it is justified and indicated in many suspicious cases. We believe that were the remote terminations of one hundred cases of obscure abdominal disease treated upon the expectant plan compared with those of another hundred indiscriminately explored during the earlier stages, the results would preponderate in favor of the latter method to a startling degree. This, we believe, would be the conclusion were all classes of abdominal disease included. Limiting the series to acute cases, the favorable percentages would be again greatly increased; but, excluding therefrom all save those presenting symptoms of acute intestinal obstruction, we should expect that the terminations would overwhelmingly indicate surgical interference in every case at the earliest onset of suspicious or presumptive symptoms.

These remarks have been elicited by a recent communication to the *Archiv für Chirurgie*, 1889, Band 38, Heft 2, from PROF. VON WAHL, in which he narrates the histories of three cases of volvulus, and lays particular stress upon the likelihood and dangers of septic complications of the later stages of intestinal obstructions, and their avoidance by earlier surgical interference. His first case, a female, aged nineteen, was operated upon four and a half days after the onset of symptoms of obstruction originating shortly after a severe lifting strain. Sanguinolent serum in quantity was present in the abdominal cavity, and a coil of small intestine was twisted and bound beneath a mesenteric band in the left hypochondrium. Upon puncturing, emptying, and untwisting the intestine, the band disappeared, and the gut quickly resumed its normal appearance. The knife punctures were closed by suture, and the peritoneum irrigated. Convalescence was retarded and endangered by severe septic pneumonia, but recovery finally ensued. Case two occurred in a female pregnant six months. Abortion took place five days after the onset of obstruction symptoms, and operation was performed on the sixth day. Shortly before the beginning of pregnancy a tumor had been removed from the left side of her pelvis. Upon section, one portion of small intestine was found fixed by adhesions in several places, and around this fixed portion another loop of bowel had rotated through an arc of 180 degrees. The adhesions were separated by the knife, and the gut was then, without difficulty, unfurled. Convalescence in this case likewise was complicated by septic pneumonia, but the patient was ultimately cured. The third case was one of rare occurrence and interest. An adult male, after a severe lifting strain, soon experienced the usual symptoms of intestinal obstruction. Upon admission to the hospital three days afterward, a tumor six inches in breadth could be felt extending from right to left in a downward direction across the umbilicus. Section revealed a 180 degree rotation of the *whole small intestine* upon its mesenteric attachment, which latter made a firm constricting band. Intense congestion of the intestines and much sanguinolent serum were present. Death followed from general septic intoxication.

Von Wahl also quotes from the literature of intestinal obstruction cases where death succeeding operation was plainly caused by metastatic parotitis and pneumonia, by acute septic œdema of the glottis and lungs, and by pneumonia of the same nature as was encountered in his own cases. Septic poisoning and metastasis must, therefore, be held responsible for much of the shock, exhaustion, and subsequent complications which so often accompany cases of acute obstruction, especially by volvuli, which from their very nature should be most curable if the proper remedy is not too long withheld. For almost all varieties of the latter affection can most easily and safely be relieved by early operation; simply to untwist them is all that is usually required, but occasionally one or more adhesions must be parted or the bowel punctured before untwisting can be accomplished; thus dealt with in the early stages, the mortality should not exceed ten per cent. Hence, diagnosis of abdominal obstruction affections not having attained to the same high point of perfection as has their treatment, exploratory section should be our almost indiscriminate resource until diagnosis shall have become more exact and reliable.

WE chronicle with much pleasure the rare sense of justice shown by a municipality in its appreciation of the professional services of a physician. The municipal assembly of the city of St. Louis has just appropriated the sum of $500 to Dr. A. C. Bernays for medical attendance upon a member of the police force, from June to September, 1888, who, while in the discharge of police duty, received a gunshot wound of the abdomen, and upon whom Dr. Bernays successfully performed laparotomy.

At recent commencements the degree of Doctor of Medicine was conferred as follows:

Rush Medical College, Chicago	127
Memphis Hospital Medical College	62
University of Georgia, Augusta	53
College of Physicians and Surgeons, Chicago	48
Chicago Medical College	46
University of Buffalo	46
Detroit College of Medicine	43
College of Physicians and Surgeons of Keokuk	39
Indiana Medical College, Indianapolis	27
Woman's Hospital Medical College, Chicago	25
Arkansas State Medical College, Little Rock	22
Iowa College of Physicians	9
Georgetown (D. C.) University	8
Toledo (O.) Medical College	8

We regret to learn that a singular and painful accident has just happened to Dr. W. T. Ennett, one of the Vice-Presidents of the North Carolina State Medical Society, on the 17th instant. He was visiting at Garysburg, and was sitting before a fire-place, when suddenly a pulmonary hemorrhage came on. He became unconscious therefrom, and slipping forward his feet came in contact with the fire. Before help could reach him he was very seriously burned.

By the will of the late William J. Syms, of New York City, the Roosevelt Hospital will receive $350,000. Of that amount $250,000 is to be used in the erection of a surgical operating theatre, at the easterly end of the lot on which the hospital stands. The theatre is to be under the direction of Dr. Charles McBurney, and to be called the "William J. Syms Operating Theatre of Roosevelt Hospital." The remaining $100,000 is to be invested and the income applied to the expenses of the operating theatre.

The Medical College of the State of South Carolina proposes to elect a Professor of General Pathology and Practice of Medicine about the middle of next month.

In New York City, two physicians were invited to apply a so-called "hypnotic" test to an accused boy-murderer. Some persons having advanced the theory that the boy might have committed the crime while under the influence of another person's will-power, these two physicians were applied to, as experts in hypnotism, to experiment with the accused and to ascertain if he was a "subject." The results of the trials were negative, and one of the experts is reported to have said that the presumption was very strong that the boy had never been hypnotized. But what would have been the gain if the reverse had been the result?

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, April 18, 1889.

The President, Alfred L. Loomis, M.D., in the Chair.

Dr. E. F. Brush read a paper on

THE RELATIONSHIP EXISTING BETWEEN HUMAN AND BOVINE TUBERCULOSIS.

Tuberculosis was not, he said, as many suppose, the result of civilization, since barbarous and uncivilized races were afflicted by it as severely as many of the most advanced civilized races. Neither geographical position nor climatic conditions were a factor in its distribution, although every known part of the globe, with the exception of a few isolated areas, was a habitat of the disease. After several years of close study of the affection, including a consideration of all accessible statistics and the habits of the people where it prevails, he had arrived at the conclusion that the only constantly associated factor is found in the in-bred bovine species. If a community was closely associated with in-bred dairy cattle tuberculosis prevailed there. In Hirsch's work on *Geographical Distribution of Phthisis*, it was stated that in Cape Colony this disease is oftenest met with among the Hottentots inhabiting the plains near the coast. These people are great milk-drinkers; they suck the blood from the jugular vein of the living bullock, and they churn together blood and milk for a drink; Professor Law, in his *History of the Ox*, informs us that in the vast regions of Southern Africa cattle abound and multiply, and proof that these African cattle are in-bred is found in the writings of Darwin and others. These facts relating to the cattle-breeding propensities of the negroes account for the statement of Daniel that phthisis is widely prevalent and very malignant among the people of the West Coast of Africa. In the interior plateaux of Southern Africa, on the other hand, the disease hardly ever occurs; and this immunity could be accounted for by the presence of the tsetse fly, since, where this insect exists, cattle, horses, and dogs cannot live.

Coming to the civilized world, Dr. Brush first drew a comparison between Denmark and Iceland, where the climatic conditions are nearly the same. In Denmark, where there is one cow to every $1\frac{5}{7}$ of the human population, phthisis was found to be very common, and with a high rate of mortality; while in Iceland, where there is only one cow to four individuals, the disease was extremely rare. And it is a fact that the only people on the face of the globe who enjoy an absolute immunity from phthisis are those who are not in possession of the domestic cow. Thus, among the Kirghises on the steppes of Russia, who consume large quantities of mare's milk, and eat the flesh of horses and sheep, but have no cows,

a case of phthisis, according to Dr. Naftel and other authorities, was never known. The Esquimaux also enjoyed the same immunity because they had domesticated the reindeer and not the cow.

In considering the statistics of Europe it would be found that the prevalence of phthisis is regulated by the ratio of the bovine to the human race; and he thought there could be little doubt that the in-bred species of the bovine race is the prime etiological factor of tuberculosis in the human race. They not only fostered the germ, and prevented its extinction, but sowed it in the human race continually and abundantly. Without their aid the germ would perish, for of all germs known, none had so hard a struggle for existence in man as the bacillus of tubercle; as was shown by the fact that of the immense number of individuals who are exposed to the infection, so comparatively few contract it.

The cow was the only known animal that had transmitted tuberculosis to her offspring in inheritance. After diligent search he had failed to find a single well-authenticated case on record of a human fœtus at term showing evidence of tuberculosis; but in 1885 Johne had placed on record an undoubted case of congenital tuberculosis in a fœtal calf of eight months.

In conclusion, Dr. Brush said man cannot generate new forms, but he can so control and interfere with Nature's processes as to modify the original design. In-bred cattle are selected, sheltered, and pampered, so that they would be unable to withstand the rigorous conditions of the wild state. They propagate earlier, are larger milkers, and are more efficient beef-producers, while their meat is more delicate and tender than that of the wild animal. All this is achieved by man at the expense of his own health.

DR. H. M. BIGGS very strongly dissented from these conclusions. He believed that the statistics given were not strictly true; but even if they were true, he did not think they would prove the correctness of the position taken by Dr. Brush, since they left out of consideration all the other factors concerned in the production of tuberculosis. He had left entirely out of account the influence of age, altitude, and occupation, which had been shown to be very important etiological factors. There was the strongest evidence that tuberculosis could be transmitted by milk; yet notwithstanding this it was certainly true that the disease was not often conveyed in this way. If this was the case, the disease ought to be much more common among young children, who live almost entirely upon milk, than among any other class of individuals; while, as a matter of fact, it was extremely rare among this class. The facts appeared to show that phthisis is most common among the most highly civilized nations, and among the native populations of uncivilized countries who are brought into more or less constant contact with foreigners from civilized countries.

In all civilized countries there were to be met with other elements (particularly that of occupation), which enter into the causation of the disease. Confinement in close, ill-ventilated apartments had a most pronounced effect upon males and females alike. More than this, Dr. Brush's theory was entirely inadequate to account for the marked prevalence of the disease among armies and the inmates of prisons.

Again, other things being equal, phthisis was found to prevail in proportion to the density of the population. According to the Brompton Hospital reports, 70 per cent. of the patients suffering from phthisis had been accustomed to spending their time in hot and dusty rooms. As regards the distribution of the disease among different classes, in every 1000 deaths, 168 of the patients were grocers, 108 tailors, and 301 drapers; while nearly 500 printers died of phthisis. He could not but regard the conclusions of the paper as unfortunate, especially if they should be accepted, since they would have the effect of diverting attention from the most important mode of origin of phthisis, viz., transmission from the human subject.

If the disease were derived from animals it could only be through the avenue of the alimentary canal, and it was a well-established fact that the number of cases in which the infection enters the system through the alimentary canal are exceedingly few. In the case of animals fed on tuberculous matter the resulting tuberculous disease, when such occurred, was found to be located in the alimentary canal, not in the lungs; and there was every reason to believe that the same would be true in the case of the human subject. It seemed to him ill-advised to look for the cause of the trouble in this unlikely source, when there were so many ready ways by which the human system might become infected with tuberculosis. One of the most prominent of these was undoubtedly the sputa of tuberculous patients. The sputa of all such individuals abounded in tubercle bacilli, and when it was remembered how large was the quantity of the expectoration of consumptives and for how long a time the disease often lasted, it could well be appreciated what a source of danger to others this constituted. The sputum was apt to be scattered all around, and on its becoming dry, the bacilli it contained often floated about with the dust in the air. The bacillus was the universally recognized special cause of tuberculosis, and it might thus be seen how readily it could be inhaled in this way, and so brought into direct contact with the lungs, which were the ordinary seat of the disease. We had no proof that the meat of tuberculous animals taken into the stomach was capable of producing tuberculosis of the lungs; and, moreover, it was a fact that the viscera and not the muscles of tuberculous animals were affected with tubercle. In tuberculous animals, furthermore, the milk was not infected with the bacillus unless the mammary glands were implicated in the tuberculous disease.

The sputum of tuberculous patients was, therefore, the chief agent by means of which the disease was spread; and, although he felt convinced that a much larger number of cases really originated from animals than was generally supposed, yet this class constituted but a small number of all the cases of phthisis.

DR. FORREST said that in the Southern States there were certain sections where phthisis was almost wholly unknown among the whites, but was very common among the blacks. Yet it was well known that far more fresh beef and milk was consumed by the white population than by the negroes, who lived principally on corn and pork. It was also a fact that a very fine stock of cattle was now raised in these same districts. He could not see how, therefore, that the condition of affairs which he had described could be reconciled with the theory of Dr. Brush.

THE PRESIDENT said it seemed to him that the posi-

tion taken by Dr. Brush was too narrow a one, and that any one who assumed that phthisis is due to one cause alone was begging the question. It was a disease that had many causes, and the bacillus which constituted its special etiological agent would not give rise to it unless it met with conditions which favored its development. Among the conditions to be taken into consideration were climate, hygienic surroundings, heredity, and soil, and a long list of causes must be in operation before the bacillus was able to do its specific work. This, he believed, was a point which should not be lost sight of.

Dr. Brush said that he thought that his position had been misunderstood. He did not wish to imply that the disease was derived alone from the cow. All that he claimed was, that wherever in-bred cattle existed, there was found phthisis also. He needed no proof to show that but a small proportion of individuals who were exposed to the infection contracted the disease, since, although the number of deaths from phthisis in every civilized community was appalling, it would be infinitely greater than it is if this were the case. He had frequently known of children drinking the milk taken from cows dying of tuberculosis, and yet there could be no question that the large proportion of them escaped infection. In addition to the bacillus, there must be present the conditions favorable to its development. But, at the same time, he believed that the disease was originally derived from the bovine species. He did not believe that less than fifty per cent. of all dairy cattle were affected with the disease, and the statistics which he had quoted showed that wherever there was a race of people without cattle phthisis was unknown. He believed, furthermore, that if all the cattle in this country were to be killed, the disease would finally die out entirely here.

He did not wish to rely on statistics except so far as they substantiated the main point that he made, that wherever cattle existed, there phthisis also existed.

The practical outcome of the whole matter, to which he wished to call special attention, was, that the prevalence of phthisis could undoubtedly be diminished by properly regulating the breeding of cattle by law, so that the in-breeding now so common might be done away with.

Section on Pædiatrics.

J. Lewis Smith, M.D., Chairman.

Stated Meeting, March 14, 1889.

Dr. H. W. Vineberg presented a case of

laryngismus stridulus and eclampsia associated with rachitis

in a male child, nine months old, of good family, and who had never suffered injury except once when it fell out of bed. Some time after this accident the child was attacked with laryngismus stridulus with severe convulsions, three or four attacks coming on each day. On examination the patient was found to be fat, flabby, anæmic without craniotabes or bone deformity. The temperature was normal; the urine was not examined. No improvement followed the administration of calomel, cod-liver oil, or ol. phosphoratum. After ten grains of potassium bromide were given twice daily the attacks ceased. At the present time the child is taking wine of iron.

Previous to 1843 laryngismus stridulus was supposed to have some connection with the thymus gland. Friedleben and others have pointed out its frequent association with rachitis. Reflex irritation from almost any part of the body may bring on an attack. The morbid anatomy of the subject has as yet not been cleared up. Attacks of asthma and stridulous croup are sometimes mistaken for true laryngismus. The prognosis is grave. The treatment should be directed to the attack and the interval between attacks. Warm baths, cold douches, tickling the fauces, the bromides, musk, apomorphia, and belladonna are recommended; also phosphorus and cod oil.

Dr. Jacobi remarked that the arytenoid (adductor) muscles are supplied by the recurrent laryngeal nerve; reflex irritation may be central or peripheral, as from the stomach, bronchial glands, mediastinal tumors, or enlarged thymus; the latter may cause sudden death by local pressure in children with a small sterno-vertebral diameter. Cranial rachitis is the usual central cause and prolonged apnœa may occasion sudden death.

Dr. Vineberg also presented as a case of

tetany,

a child fifteen months old, having but four teeth and suffering from diarrhœa; the feet, hands, and fingers were flexed through contracture of the muscles.

Dr. J. Lewis Smith remarked that the case was probably one of idiopathic contracture as described by Henoch in his treatise on children's diseases. He remembered having seen three such cases.

Dr. C. H. May read a paper on

scarlatinous otitis.

According to different authors, four to five per cent. of all aural affections are due to scarlatina. Burchard Marion reports that of 5613 deaf-mutes ten per cent. became so affected in consequence of scarlatina. The diagnosis in young children is difficult to make. As a rule, the little ones press the affected side into the pillow. Chills, convulsions, pain, restlessness, a stupid gaze are the usual symptoms; the glands are swollen. The purulent and diphtheritic variety present severe symptoms and a tendency to tissue necrosis. The prognosis is influenced by treatment and is usually good.

Treatment: An ice bag to the temporo-maxillary region, or hot fomentation, or tincture of iodine, or leeches are applied behind the ear. Injections of hot salt water and cocaine, ʒj ad. Oj, into the ear will control pain. In noticeable congestion and bulging of the membrana tympani paracentesis should be performed. To facilitate the discharge of pus the ear may be inflated by means of a catheter or Politzer's bag. A catheter should not be employed in children under four years of age. Dr. May thinks there can be no danger of forcing infectious matter into the middle ear. He does not advise packing the auditory canal with dry boric acid powder. Paracentesis should be made in the postero-inferior quadrant of the drum-head; and Wilde's incision over the mastoid process is often necessary. Pilocarpine has been recommended when the nervous

apparatus is involved, but no noteworthy results have been reported.

DR. SEXTON remarked that the inflammatory process shows two distinct varieties, it being confined either to the atrium of the ear or localized in the attic. When of the latter variety the pus may burrow upward and cause a fatal termination. In incising the membrane illumination should be obtained by electric light. Children should be etherized. Bloodletting, poulticing, douching should not be practised, as they give no relief. He preferred mild treatment and frequently administered aconite and gelseminum. Otitis media might arise from sympathetic irritation from the teeth.

DR. GRUENING remarked that in his opinion iodine applied externally could be of little value. He would not apply leeches in children who are weak from high fever of an infectious disease, on account of the danger of abstraction of blood; furthermore, he advises early incision, especially if the membrane is densely red. The ear can be illuminated by means of an ordinary light. A distinction between pus in the atrium or attic is superfluous. To remove pus from the ear he aspirates, because the use of the catheter or Politzer's bag is liable to force infectious material into the ear. In conclusion he stated that dentition has nothing to do with otitis.

DR. POMEROY spoke of the value of diminishing hyperæmia of the parts by means of leeches and aural douches of salt water in order to prevent the attack from becoming formidable. He also employs the hot water bag and opium. After puncture he uses the Politzer bag and no catheter in children. Packing the auditory canal is fruitless in acute cases but should be employed in chronic cases. Should a swelling present itself behind the ear he should cut down upon its apex into the soft bone.

DR. POOLEY objected to the term scarlatinous otitis, a special name being unnecessary. In the treatment the element of rest was very important. Local abstraction of blood he thought advisable. Hot water should be applied by means of a medicine dropper, and the ear kept clean by syringing. He believed the use of the catheter or bag to be injurious in acute cases.

DR. MAY closed the discussion by stating that Politzer's inflation was certainly indicated in retention of pus.

SECTION ON THEORY AND PRACTICE OF MEDICINE.

R. C. M. PAGE, M.D., IN THE CHAIR.

Stated Meeting, April 16, 1889.

DR. M. ALLEN STARR read a report on

SIMULO IN THE TREATMENT OF EPILEPSY.

In March, 1888, Dr. W. H. White, of London, published in the *Lancet* some observations on the use of simulo in the treatment of epilepsy. The drug was employed in the form of a tincture made from the kernel of the pit of the fruit of the simulo plant (capparis corriacea), which was given in one to two drachm doses three times a day. Having given a brief description of the simulo fruit, Dr. Starr stated that the tincture is of a yellowish-brown color and has an aromatic taste, reminding one slightly of sherry.

Dr. White reported seven cases of epilepsy treated by his agent, all of them being cases in which several fits occurred every week. In the first case neither simulo nor bromide was of any particular benefit. In the other cases there was considerable improvement under the use of simulo, and in case number seven, which was one of unilateral spasms with paresis, the spasm was very much relieved by the drug, although it had not been affected by larger doses of the bromides. He concluded his report by stating that he would not have it thought that simulo will cure epilepsy, but he believed that an improvement occurs under its use, and that it may be used as a substitute for the bromides when these produce ill effects.

In August, 1888, Eulenberg, of Berlin, published a report of seven cases treated by simulo, four of them being epileptic, and three hysterical in character. It appeared to have no effect whatever in the cases of hysteria, and in three of the cases of epilepsy its effect was found to be weaker and less certain than moderate doses of the bromides (90 to 120 grains daily). In the fourth case, in which the use of the bromides for years had not succeeding in reducing the number of attacks below four to eight in a week, the effect of maximum doses of simulo (six drachms daily), was to reduce the number of attacks to two to five in a week. Subsequently Eulenberg combined the bromides with simulo, giving a half dose of each, and the effect was at first as favorable as under the use of large doses of simulo alone. The frequency of the attacks gradually increased, however, and finally the patient was put back upon the bromides alone. Eulenburg's conclusion was that while simulo is not without use, it is decidedly inferior to the bromides in its effects.

Dr. Starr procured some tincture of simulo from the manufacturers, Christy & Co., of London, and in October last commenced its trial on a number of epileptic cases of extreme severity, which seemed to offer the conditions for a fair test of the powers of the drug.

Case 1 was a female, forty-eight years of age, who had had hysteria and epilepsy since the age of sixteen. The effect of the bromides was to reduce the attacks of petit mal, from which she suffered, from four to six daily to one or two daily, and also to reduce decidedly the frequency and severity of her attacks of grand mal, which without treatment occurred about once in two months. The use of bromide was attended with such bad effects, however, that it was found impossible to keep it up continuously, and as no other agent (with the exception of nitro-glycerine, which always had a favorable effect upon the petit mal attacks, but none on the grand mal attacks) had been found of service, the case was a very difficult one to manage. This patient was kept for two months on tincture of simulo; but, while for a time it prevented the occurrence of an attack of grand mal, it failed to arrest hysterical attacks or attacks of petit mal, and as the petit mal attacks increased under its use, it was then thought best to suspend the treatment.

Case 2 was a girl, twelve years old, who had had epilepsy ever since infancy, her attacks consisting of slight convulsions with loss of consciousness and loss of urine. The bromides had been used without any marked effect. Under the use of tincture of simulo, the dose of which was gradually increased from half a drachm to two drachms three times a day, the number of attacks became reduced from about five a week to

about three a week, while their severity diminished, and she no longer lost control of the bladder.

Case 3 was a girl of sixteen, who had suffered from epilepsy with both grand mal and petit mal attacks for two years. The simulo, in doses of two drachms three times a day, had no effect upon the petit mal attacks, but diminished the grand mal attacks from sixty-three attacks in a month (December, 1888, before the drug was commenced) to four attacks in a month (in February, 1889, the simulo having been commenced January 8th). During the month of February she had seventy-five attacks of petit mal. During the month of March, however (the simulo having been stopped February 26th), on bromide, chloral, and belladonna with nitroglycerine, she had no grand mal attacks and but eighteen petit mal attacks.

Case 4 was a girl of fifteen, who had attacks of grand mal since the age of twelve. The attacks occurred about every three weeks, in spite of bromide treatment. On February 9, 1889, she was placed on tincture of simulo, one drachm three times a day. On February 16th she had an attack, and on February 23d the dose was increased to two drachms. Up to April 16th no attacks had occurred; this being an interval of eight weeks, instead of the usual interval of three weeks.

Case 5.—John H., aged eighteen, had convulsions as a baby, but was free from them until the age of fifteen, when he had an attack of grand mal. Such attacks had recurred at shorter and shorter intervals, and when he applied for treatment, January 31, 1889, he had had one attack every month for several months. He was put upon tincture of simulo (six drachms daily), and reported on March 30th that he had no attacks since the treatment begun.

Case 6.—Max L., aged twelve, has had epilepsy ever since the age of two years; attacks of grand mal about once a month and attacks of petit mal several times a day. He was put upon tincture of simulo (six drachms daily) December 26th, and took it continuously until March 11th. During this time he had no attacks of grand mal, but the attacks of petit mal continued as before.

Case 7 was a young man of nineteen, who had had procursive epilepsy since the age of seven, the attacks consisting of a sudden pallor, followed by a flushing of the face and a sudden uncontrollable movement of the body. These attacks had never been controlled by bromides, and during the year 1888 they averaged one hundred every month. Tincture of simulo also had no effect upon them; but under the use of nitroglycerine combined with bromides they were reduced one-half. In addition, this patient had nocturnal convulsions, and the simulo was found to have a decided effect upon these attacks of grand mal, although the results obtained from it were inferior to those from the bromides. The case manifested many signs of abnormal cerebral development and showed tendencies toward paranoia.

The conclusions drawn from these cases by Dr. Starr were as follows:

1. Tincture of simulo has no effect upon attacks of hystero epilepsy or upon the hysterical state.

2. It has no effect in modifying the frequency or severity of attacks of petit mal or of procursive epilepsy.

3. It has some effect in modifying the frequency and severity of attacks of grand mal, but is inferior in this respect to the bromides.

4. In cases where for any reason it is deemed necessary to suspend the bromides, it would be well to substitute simulo for them.

There seemed to be no ill effects from the use of the drug. He found no evidence of change in the rate or character of the pulse or respiration or other physiological effects produced by the doses employed, and he thought it would be well to increase the dose progressively until one or even two ounces are used daily. The chief objection to its use at present is its costliness, the price being 25 cents an ounce. The suggestion of Eulenberg that it would be well to obtain and use the active principle of the drug, he thought worthy of consideration.

Dr. E. D. Fisher said that he had had no practical experience with the use of the drug, as its costliness was such that he had not felt justified in trying it in dispensary practice. His attention had been first directed to it by Dr. White's article in the *Lancet* in March, 1888, referred to in the paper. It would certainly be a great advantage, he thought, if we could get any agent which would at all take the place of the bromides in those cases of epilepsy where the use of the latter was attended with bad effects. The tincture of simulo, so far as employed, would seem at least to have no bad effects. Dr. Starr had expressed no opinion as to the mode of action of this drug, and he thought some information on this point was desirable, as nothing had as yet, so far as he knew, been published regarding it. On the whole, simulo seemed worthy of a further trial. In some of the cases reported it appeared to do well when given in connection with the bromides, and he would like to inquire if Dr. Starr had ever used it in this way.

Dr. Landon Carter Gray said that he could only agree with Dr. Starr as to the uselessness of simulo in epilepsy. He had tried it in several cases, (at least four or five), both alone and in combination, and had obtained from it no results except such as one could get in almost any case of epilepsy by changing the drugs employed. This was merely a temporary effect, and the same could be obtained by a hundred other agents. He had, therefore, discontinued the employment of simulo, as it had in his hands proved so nearly useless as not to afford sufficient encouragement to give it a more extended trial.

Dr. Starr said, in answer to Dr. Fisher's question, that he had not tried simulo in combination with the bromides.

CORRESPONDENCE.

ACUTE MELANCHOLIA AS A SEQUEL OF GYNECOLOGICAL OPERATIONS.

To the Editor of The Medical News,

Sir: Dr. T. Gaillard Thomas, in a paper read before the New York Academy of Medicine, April 4, 1889, entitled "Acute Mania and Melancholia as Sequelæ of Gynecological Operations," said: "There is very little literature extant upon this subject, which, until recently, has appeared to attract no attention. For obtaining what little there is I am indebted to two of my friends, Dr. Paul F. Mundé and Dr. Andrew J. McCosh, who have kindly looked it up for me. *Prior to the year 1887 there is nothing.*"

Mr. Lawson Tait, in a lecture delivered at the Jefferson Medical College Hospital, September 13, 1884, called "Abdominal Section in Disease of the Uterus or of the Uterine Appendages," and published in THE MEDICAL NEWS of September 27, 1884, spoke thus:

"Removal of the uterine appendages. . . . . After the operation. . . . . So far we have not had any trouble, except *from one thing, and this a distressing one*. It occurs after all sorts of abdominal operations, after exploratory incisions, after the removal of one ovary for cystoma, after the removal of both ovaries for cystoma, and after hysterectomy. I refer *to the occurrence of acute melancholia*. All the cases of mental alienation that I have seen following these operations are seven in number, and all have taken the direction of this most unfavorable form of insanity—acute melancholia. I cannot say that any one of them is likely to recover. I do not know that this is a necessary result in a certain number of cases. I have performed abdominal section some 960 times, and in this number I have met with 7 cases of acute melancholia. Of course, a good many of these cases died, especially in the earlier years of my practice. We may state that acute melancholia occurs in about one per cent. of those submitted to abdominal section. I do not know that anything like this follows other surgical operations. This is the only after-result of an objectionable character with which I am acquainted."

During the meeting of the New York Academy of Medicine, April 4, 1889, at which Dr. Thomas read the above-mentioned paper, Dr. Landon Carter Gray thought "that Dr. Thomas deserved the credit of having described *a new genus of insanity*, having related six cases and referred to twenty others."

Finally, Dr. Thomas expressed "the hope that other cases would be reported as they occurred, and that the subject would be investigated more thoroughly."

HENRY A. SHELLEY, M.D.

319 EAST ONE HUNDRED AND TWENTIETH STREET,
NEW YORK CITY.

AUTOMATIC AMBULATION.

To the Editor of THE MEDICAL NEWS,

SIR: Under the above title two cases of a rare form of epilepsy have been described. As Dr. Starr truly said, it was known before the case reported by Dr. Donaldson.

In Strümpell's second volume, page 429, in his article on epilepsy, he describes a form of psychical attack. This is given the name of "*Psychisch-epileptischen Aequivalente*." This is identical in character with the cases described by Dr. Starr and Dr. Donaldson. In Prof. Westphal's clinic, in January, 1888, the writer saw a patient suffering from this form of epilepsy. The attacks were, however, of short duration, rarely exceeding five minutes. But during that time the patient's acts were clearly those of a person with changed consciousness, for they had no relation to what she was doing immediately before the attack or to what she did immediately after the attack was over. She remembered nothing of what she did at these times of changed consciousness.

Very respectfully,

JAMES W. PUTNAM, M.D.

388 FRANKLIN ST., BUFFALO, April 19, 1889.

OBITUARY.

SAMUEL W. GROSS, M.D.

SAMUEL W. GROSS, M.D., LL.D., Professor of the Principles of Surgery and Clinical Surgery in the Jefferson Medical College, died on Tuesday, April 16th, at his home in Philadelphia, in the fifty-third year of his age. He was taken sick about the 25th of March, and typhoid pneumonia developed, marked by high temperatures and an almost constant delirium, from the effects of which he sank. He was attended in his last illness by Drs. Da Costa, Osler, Horwitz, and Wirgman, and was unremittingly watched and nursed.

Dr. Gross was the eldest son of the late Prof. Samuel D. Gross, and was born in Cincinnati, February 4, 1837. He was educated at Shelby College, Kentucky, began the study of medicine at the Medical Department of the University of Louisville, and continued it at the Jefferson Medical College of Philadelphia, in the session of 1856–57, and from which he was graduated in March, 1857. After a visit to Europe, he settled in Philadelphia and commenced the active practice of his profession, acting for a time as co-editor of the *North American Medico-Chirurgical Review*. When the war broke out in 1861, he at once entered the service of the United States. He was appointed Brigade Surgeon (U. S. Vols.) August 3, 1861, and was on duty with General Thomas's command, Army of the Ohio, and as Medical Director, Fifth Division Army of the Ohio, until July, 1862, and subsequently at De Camp General Hospital, David's Island, New York Harbor, until July 28, 1863; and at Draft Rendezvous, Riker's Island, New York, to August 26, 1863. He was then ordered to Hilton Head, South Carolina, and from September to November, 1863, was in charge of Field Hospital, and Surgeon-in-Chief at Morris Island, South Carolina. In January and February, 1864, he was Chief Medical Officer Northern District, Department of the South, and from March to May, 1864, was on duty as Medical Director District of Florida, at Jacksonville, Florida. In June, 1864, he was assigned to the Department of the Susquehanna, and was on duty at Haddington General Hospital, Philadelphia, Pa., until May, 1865. He was mustered out of service June 24, 1865. He was brevetted Lieutenant-Colonel, June 1, 1866, and his commission sent him June 15, 1866. In the discharge of his military duties Dr. Gross evinced remarkable efficiency and ability, and was greatly beloved by the officers with whom he was associated.

At the conclusion of the war he returned to Philadelphia, and again entering into practice, became surgeon to the Howard Hospital, the Philadelphia Hospital, and the Hospital of the Jefferson Medical College. He was also appointed Lecturer on Genito-Urinary Diseases in the summer course of the Jefferson Medical College, and in the spring of 1882, on the retirement of his father from the chair of surgery, the chair was divided, and Dr. Samuel W. Gross was appointed Professor of the Principles of Surgery and Clinical Surgery, and Dr. John H. Brinton, Professor of the Practice of Surgery, and Clinical Surgery. His chair of Principles Dr. Gross held until his death, his last clinical lecture being delivered only a few days before he was taken fatally ill. Several years before his death he received the degree of LL.D.

In 1876 Dr. Gross was married, and his wife survives him.

He was an active Fellow of the College of Physicians of Philadelphia, and served for years as a member of the Library Committee. At the death of his father, in 1884, he was elected President of the Board of Trustees of the Pennsylvania College of Dental Surgery. He also served as President of the Pathological Society of Philadelphia.

Dr. Gross's contributions to journalistic literature and to the proceedings of societies were many and various. In the *North American Medico-Chirurgical Review* for January, 1859, he published "A Case of Aneurism of the Right Femoral Artery cured by Digital Compression, with remarks, and a statistical report of twenty-two other cases treated by this method." In the *American Journal of the Medical Sciences* for 1869, he reported "A Case of Poisoning from Atropia;" in the same journal for January and April, 1867, he published an elaborate article on "Wounds of the Internal Jugular Vein, and their Treatment," strongly advocating the ligation of the vein. In the October number of the *Journal* for the same year, he wrote a most able review of sixty pages on eleven works on military surgery in English, French, and German. In this he entered extensively into gunshot injuries of the head and of the joints, and presented the statistics of 13,514 amputations for gunshot injuries, a number which he subsequently increased to 20,933 in the sixth edition of Gross's *Surgery*. For the April, 1871, number of the same journal, he wrote a valuable paper on "Ulceration of the Jugular Veins, communicating with an Abscess or Open Sore."

The study of tumors and of malignant disease was one which possessed peculiar fascination for him. In July and October, 1879, he published in the *American Journal of the Medical Sciences* a valuable paper based upon much original investigation on sarcoma of the long bones. This paper, as also his treatises on mammary tumors, in 1880, was in part the outcome of his Mütter lectures on Surgical Pathology, delivered before the College of Physicians of Philadelphia. In the *Transactions of the American Surgical Association* for 1881 and 1882, he published articles on carcinoma of the breast and on the resulting cicatrices after operation, and in the *Transactions* for 1883 he reported a case of nephrectomy for medullary sarcoma and partial cholecystectomy for calculus upon the same subject. In 1884, he read a paper before the Association on "Stricture of the Œsophagus, and the Operations for its Relief," and in 1887, one on the "Prognosis of Sarcomata of the Breast," in which his own results were largely embodied. In the March and April numbers of the *American Journal of the Medical Sciences* for 1888, he published a "Clinical Study of Carcinoma of the Breast and its Treatment." In this paper particular attention was given to metastatic deposits, and Dr. Gross described and pictured his own method of operating, and insisted upon the necessity of opening the axilla, and on the complete removal of all involved or suspected glands.

He also prepared for the second volume of the *American System of Gynecology*, edited by Dr. Mann, a voluminous article on "Tumors of the Breast," in which the doctrines he held and taught on the pathology, clinical characters, and treatment of these affections are vividly set forth.

In 1880, Dr. Gross published his *Treatise on Tumors of the Mammary Gland*, embracing their histology, pathology, diagnosis, and treatment. On tumors of the female breast, Dr. Gross has been recognized as an authority both at home and abroad. His accurate knowledge of the pathological anatomy of these affections guided him in his clinical treatment which undoubtedly was pre-eminently successful. In 1881, his *Practical Treatise on Impotence, Sterility, and Disorders of the Male Sexual Organs* appeared. Both of these works passed to second editions. He also at various times did much to assist his father in the preparation of the successive editions of Gross's *Surgery*. In 1876 he edited his father's treatise on *Diseases, Injuries, etc., of the Urinary Bladder*, and in 1887, in conjunction with his brother, A. Haller Gross, Esq., he edited the autobiography of his father.

As one of the staff of The Medical News he was a frequent and valued contributor to our pages, and his articles were always characterized by surgical acumen, breadth of view, fidelity to detail, learned research, clearness of expression and practical application.

From this summary of his lifework, it will be seen that his pen was never idle. He was always writing something, and as soon as one paper appeared, he busied himself in the preparation of another. He endeavored to have a contribution for each annual meeting of the American Surgical Association. He was not merely a reporter of cases; his aim was far higher; he sought in a true philosophical spirit, by the study of groups of cases and pathological conditions to arrive at the cause of disease, and to grasp the great principles of clinical treatment. His ultimate object was the cure of disease and the alleviation of human suffering. All studies were with him secondary to these ends, and to attain them, he labored continuously, wisely, and, we may say, successfully to a marked degree.

But the last labor of his life, and one of which he often spoke to the writer of this notice, with an energy and enthusiasm all his own, was a paper on "Stone in Children, and the Operations for its Relief," to appear in the forthcoming *Cyclopædia of the Diseases of Children*. To solve the question of the proper operation he had undertaken a thorough search through periodical literature for extensive data from which to deduce his conclusions, and to the same end he had written many letters, seeking the experiences of surgeons and hospitals at home and abroad. The arrival of each answer was warmly welcomed, and the information it gave recorded with delight. His unfinished notes and criticisms, his unused data, now rest on his office table, and it is a sad reflection that in the delirium of his fatal illness his mind constantly reverted to the cherished thoughts of his last working hours.

Dr. Gross took a deep and active interest in the medical societies with which he was connected, and especially in the American Surgical Association, which was founded by his father, whose profile is borne upon its seal. In his attendance at medical gatherings he was by no means a passive or silent member. He was a progressive man and, having greatly at heart the welfare of the profession and the advancement of medicine, his voice was often heard, and with no feeble or uncertain meaning. His utterances carried weight, not only because of the soundness of his views, but also from the

bold, honest, and straightforward manner in which he advocated them.

He was a learned surgeon, deeply versed not only in the medical literature of his own language, but also in that of Germany and France. He was a constant reader of periodicals, reports, and transactions of societies. His memory was retentive, and the precise information thus stored up, was always at his instant command. His professional judgment was unusually correct, and his surgical treatment was based on an accurate knowledge of the pathological anatomy of diseased or injured parts.

As an operator he was bold and self-reliant. He was systematic in the highest degree. Every step in the operation was thoughtfully planned, and boldly, judiciously, and promptly carried out. He was fertile of resource, undaunted, and well able to meet and deal with the contingencies of operative surgery. He was a thorough and careful operator, seeing to the final steps and dressing of an operation with an unremitting attention. His operations were well done to the end.

As a lecturer Dr. Gross was eloquent, earnest, and enthusiastic. He was loved and respected by his class, who fully appreciated his rare power of imparting knowledge and his unflagging efforts for their instruction. He was indeed a model teacher. His style was clear, logical, and terse. He taught in an eminent degree principles; and seeing clearly, he sought to make others see. He succeeded, and his lectures, didactic and clinical, were thronged with listeners of maturer years, who came to profit by his lessons.

In manner he was energetic and quick. In thought and discussion he at once went to the gist of a matter, and impressed all as a man of force and decided character. He was warm-hearted and hospitable, and to the young and struggling physician he was more than a friend, ever ready to lend a helping hand, and often rendering benefactions in secrecy and silence. To those who stood near to him and knew him best, he was most kind and gentle, a faithful friend, loyal in times of trouble, tender, and true. In life he was loved and honored; the void he leaves will be not easily filled, and his memory, entwined with that of his father and predecessor, will long endure.

NEWS ITEMS.

In Memoriam.—At a meeting of the Philadelphia County Medical Society, held April 17th, a minute was adopted expressive of regret for the death of Dr. Bruen and esteem for his services. We make the following extracts:

"Dr. Edward Tunis Bruen, late Vice-President of this Society, has been removed from our midst by the relentless hand of death. Never physically strong, especially since receiving his degree in medicine in 1873, he rapidly succumbed to an attack of double croupous pneumonia, which proved fatal Sunday, March 31st, less than a week from its incipiency. Despite his apparent lack of strength he exhibited a remarkable endurance, and accomplished a vast amount of work in varied lines, as teacher, writer, and practitioner. As a student he seemed indefatigable, as evidenced by his familiarity with medical literature, as well as by his services on the staffs of so many hospitals.

"His writings were extensive, not only for the many societies of which he was a member, but also of original articles for the medical journals, and for comprehensive systems of medicine. He was also a popular private preceptor, and had numbers of students constantly under his direction.

"Personally Dr. Bruen was a delightful companion, whose native refinement and rare geniality made him prominent in every gathering which he graced, and made him always welcome to a very large circle of professional friends.

"This Society has lost through his death an active, interested, and highly valued member, in the prime of his usefulness; and many of us feel the loss of a loved and never-to-be-forgotten friend."

AT a meeting of the German Medical Society of Philadelphia, held April 8, 1889, the following minute was adopted:

"The German Medical Society of Philadelphia records with profound sorrow the loss of its honored member, Dr. Edward T. Bruen, whose wide and growing fame as a scientist, as well as whose rare personal qualities, have won for him high honors and the affectionate regard of all who knew him."

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 16 TO APRIL 22, 1889.

SMITH, A. K., *Lieutenant Colonel and Surgeon.*—Reports the address of the New Army Building as at No. 39 Whitehall Street, New York City, April 18, 1889.

WILLIAMS, JOHN W., *Major and Surgeon.*—Died at Jackson Barracks, Louisiana, April 15, at 5.06 P.M.

HAPPENSETT, JOHN C. G., *Major and Surgeon.*—Is relieved from duty at Willett's Point, New York, and ordered to report to the commanding officer Atlanta Barracks, Georgia, for duty as Post Surgeon at that post.—Par. 12, *S. O. 88, A. G. O.*, April 16, 1889.

EWEN, CLARENCE, *Major and Surgeon.*—Promoted Surgeon U. S. Army, with the rank of Major, to take effect April 15, 1889.

Pursuant to instructions received from the Adjutant-General's Office, Washington, April 13th, the following-named medical officers will assemble with troops in New York Harbor, on the 27th instant, prepared for field service in connection with the New York Centennial parade: ROBERT H. WHITE, *Major and Surgeon;* CLARENCE EWEN, *Major and Surgeon;* JOHN J. COCHRAN, *Captain and Assistant Surgeon;* and CHARLES B. EWING, *First Lieutenant and Assistant Surgeon*—*S. O. 90, Headquarters Division of the Atlantic, Governor's Island, New York City*, April 19, 1889.

WOODRUFF, CHARLES E., *First Lieutenant and Assistant Surgeon.*—Is relieved from duty at Fort Mackinac, Michigan, and ordered to Fort Gaston, California, for duty.—Par. 14, *S. O. 86, A. G. O.*, April 13, 1889.

MCKEE, JAMES C., *Lieutenant-Colonel.*—Leave of absence granted in S. O. 44, A. G. O., February 21, 1889, is extended seven days.—Par. 11, *S. O. 86, A. G. O.*, April 13, 1889.

POLHEMUS, ADRIAN S., *Captain and Assistant Surgeon.*—Is relieved from duty at Fort Gaston, California, and ordered to Fort Monroe, Virginia, for duty.—Par. 14, *S. O. 86, A. G. O.*, April 13, 1889.

APPEL, AARON H., *Captain and Assistant Surgeon.*—Is granted leave of absence for twenty-one days.—Par. 1, *S. O. 38, Headquarters Division of the Missouri*, April 16, 1889.

Under authority from the Secretary of War, conveyed by letter of the 16th ultimo, from Division Headquarters, the post of Fort Sisseton, Dakota, will be discontinued from June 1, 1889.—*S. O. 35, Headquarters Department of Dakota, St. Paul, Minnesota*, April 8, 1889.

ORIGINAL LECTURES.

BRIGHT'S DISEASE AND ITS TREATMENT.

A Clinical Lecture delivered at the Philadelphia Hospital.

BY FREDERICK P. HENRY, M.D.,

PHYSICIAN TO THE PHILADELPHIA AND JEFFERSON COLLEGE HOSPITALS.

GENTLEMEN: I introduce this patient because her case is a typical one of that class of diseases to which the name of Bright is universally applied. I do not propose to discuss the question whether the widely varying appearances of the kidneys of this group of diseases represent different stages of one process or independent processes from the beginning, but intend to devote a portion of the time at my disposal to the consideration of certain symptoms common to them all, and all dependent upon the imperfect excretion of urine.

Until quite recently it has been supposed that the most poisonous ingredient of the urine is the urea, and, consequently, that the grave nervous disturbances following the diminution or suppression of the urinary excretion were due to the accumulation of urea in the blood. The term uræmia was introduced to express this view of the pathogeny of kidney diseases and was universally adopted. It is now known to be a misnomer, but it is not the only medical term that has lost its etymological significance, and will doubtless continue to be employed to indicate an assemblage of symptoms dependent upon the imperfect excretion of urine.

The adjective "uræmic" is commonly applied to a group of symptoms of the gravest character calling for the promptest application of the most powerful remedies. Of these symptoms the most prominent are coma, convulsions, and delirium. I am not prepared to advocate the abandonment of the term uræmia and its cognate adjective, although, as you will presently see, the term "urinæmia" suggested by Bouchard is much more accurate, but I would call attention to the fact, often overlooked, that it is equally applicable to a group of less conspicuous symptoms which are often the precursors of those to which I have just alluded. These slighter manifestations of uræmia are of the greatest practical importance, inasmuch as they indicate a degree of poisoning which is overcome with comparative ease.

I will mention some of these precursory symptoms to which attention should always be given by those in charge of cases of Bright's disease. One of the most striking of them is a frequent desire to micturate. This symptom has been called by Dieulafoy, of Paris, *Pollakiuria*, which is a very different thing from polyuria. In the latter the amount of the twenty-four hours' urine is increased; in the former it is not. Pollakiuria signifies that a normal or subnormal amount of urine requires for its expulsion an abnormal number of contractions of the bladder. This is often one of the earliest symptoms of Bright's disease, but sometimes it does not make its appearance until a late stage and is then one of the precursors of more marked symptoms of systemic poisoning. It is due to an irritation of the bladder by a urine of abnormal composition. Many years ago it was recommended by most writers upon the subject of gonorrhœa, and perhaps is still by some, that, in that disease, the urine should be diluted by the copious ingestion of water so as to lessen its specific gravity and render it less irritating to the inflamed parts. The theory on which this treatment is based is now known to be false, for the urine that is least irritating to the genito-urinary tract is one of which the specific gravity approaches that of the blood serum. A urine of low specific gravity irritates the bladder, and this lessened density is undoubtedly one of the causes of the pollakiuria of Bright's disease.

Other symptoms of uræmic poisoning of minor grade are noises in the ears, itching of various parts of the skin, urticaria and other skin eruptions, and vasomotor disturbances, usually in the direction of vascular spasm. This may have its seat in the pulmonary vessels and give rise to great dyspnœa, closely resembling that of a typical attack of asthma, or it may manifest itself in the external parts, especially in the upper extremity. The hand, in such attacks, may become as pale and as cold as that of a corpse. This condition of "local asphyxia" which, by the way, is not peculiar to Bright's disease, was first described by Raynaud, and is, therefore, known as Raynaud's disease. It would be more correct to call it Raynaud's symptom, as its pathogeny is various. Finally, the symptom which probably most surely indicates an approaching outbreak of violent uræmic phenomena, is *myosis* — contraction of the pupils. It is one of the earliest symptoms of experimental uræmia, making its appearance when from ten to fifteen cubic centimetres of urine have been injected into the veins of a rabbit.

When, therefore, a patient with Bright's disease complains of noises in the ears, of itching of the skin, of frequent desire to urinate while the urine is not increased in quantity and free from mucus and pus, you should regard him not as liable to become affected with, but as already the subject of, uræmia. If, in addition, you observe that the pupils are abnormally contracted, you should employ active measures to prevent the outbreak of more violent and dangerous symptoms of poisoning.

I have criticised the term uræmia on the ground that urea is not the most poisonous ingredient of the urine. This is a weak statement of the fact, for instead of being the most, it is the least toxic of all the urinary constituents. The following simple experiment proves that there are substances in urine much more poisonous than urea: Ten grammes of urea were injected beneath the skin of a guinea-pig, causing the death of the animal in two hours and seventeen minutes. Beneath the skin of a second animal were injected one hundred and twenty-eight cubic centimetres of urine containing the same amount of urea. This animal died in twenty-one minutes.

The amount of urea present in the blood in cases of Bright's disease is not believed, by those who have studied the question experimentally, to be sufficient to give rise to any poisonous symptoms. Urea is a powerful diuretic and its accumulation in the blood tends to increase the secretion of urine, so that, paradoxical as it may seem, the less urea there is in the blood, the greater is the danger of becoming uræmic. In fact, Professor Bouchard, of Paris, taking advantage of its well-known diuretic properties, has actually treated a case of uræmia with hypodermatic injections of urea.

The complex of symptoms known as uræmic is the result of poisoning not by one but by numerous substances. Leaving urea out of the question, the urine, according to Bouchard, contains six distinct poisons: 1. A narcotic, concerning which nothing further is known than that it is organic and soluble in alcohol. 2. An organic substance which possesses a strong sialogogue action. 3 and 4. Two convulsives, one of which is organic and the other mineral. 5. A poison which contracts the pupil, and 6. A poison which lowers the temperature.

When urine is injected into the veins of an animal convulsions do not occur because the narcotic poison kills it before the convulsives have time to act. These poisons have not all been isolated, but there is no question that the mineral convulsive is potassium and that the coloring matters are decidedly toxic. The former statement is proved directly by the injection of potassium, and the latter indirectly by the fact that urine decolorized with animal charcoal is much less toxic than urine that has not been so treated.

Certain alkaloidal substances known as leucomaines are found in minute quantity in normal urine and have been supposed to be the cause of the symptoms known as uræmic. They are formed in the intestine through the agency of the microörganisms contained in that part of the digestive tract. They are excreted, in part, by the bowels. Another part is retained and destroyed in the liver, while the remainder passes that organ, enters the general circulation and is excreted by the kidneys. That these substances are highly toxic there can be no doubt, and in diseases of the intestinal canal, especially in enteric fever, they probably give rise to the symptoms of adynamia known as typhoid, but experiments tend to prove that, as a rule, their part in the production of uræmic symptoms is not a prominent one. For example, the symptoms of poisoning caused by double nephrectomy ensue too rapidly to be explained by the accumulation of these alkaloids.

I could mention further facts in proof of the statement that the process of uræmic poisoning is a very complex one, but those I have given you should be enough, if not to convince, at least to induce you to study this important subject for yourselves.

I will, therefore, devote the remainder of the hour to some general suggestions concerning the treatment of Bright's disease.

In the first place, you should dismiss from your minds any idea of suppressing, or even diminishing, the albuminuria by drugs administered with the object of constringing the renal vessels, or of so modifying the albumin as to make its filtration through the glomerular vessels difficult or impossible. Such effects have been ascribed to tannic and nitric acids, but they have been weighed in the balance and found wanting. The treatment of Bright's disease must, therefore, for the most part, be dietetic and hygienic.

Before mentioning any particular articles of diet that exercise an injurious effect in Bright's disease, it should be stated that in the urine of a certain proportion of perfectly healthy persons after a hearty meal—*i. e.*, a meal containing an abundance of nitrogen, albumin may be found. It would appear, therefore, on *à priori* grounds, that albuminous substances should be administered sparingly, and clinical experience brings ample testimony in support of this inference. It may be laid down as a rule that eggs are to be discarded from the diet. Experiments on animals have proved that the quantity of albumin excreted with the urine is much greater than the amount of this substance injected into the veins—in one instance four times as much—and that the albuminuria thus excited is more or less persistent. It would seem that egg albumin to certain animals and to certain constitutions is a decided irritant to the kidneys. The same is true to some extent of meat, which should be administered sparingly, and preference given to white meats and fish, which contain less albumin than beef and mutton. Another objection to the use of albuminous substances is that they increase the quantity of urea in the blood, and whatever views may be held with reference to the production of so-called "uræmia," there is no doubt that the presence of urea in an albuminous solution increases the filtration of the albumin.

Cheese is another substance to be avoided. Fifty years ago (in 1839) Christison observed temporary albuminuria in persons who had eaten heartily of this substance.

It is sometimes argued that as albumin passes out of the system in large amount, this loss should be atoned for by the free ingestion of albuminous substances, but such an argument proceeds from ignorance of the facts of the case. In albuminuria of high degree the loss of albumin, when carefully estimated, is found to be remarkably small. It rarely amounts to more than a few tenths of one per cent., and it has been calculated by Senator that half a pound of meat contains enough albumin to cover the weekly loss of this substance in high degrees of albuminuria.

As regards fluids, alcoholic drinks should be entirely avoided, but when patients insist that they cannot do without such beverages, which is equivalent to saying that they will not, they may be advised, out of a variety of evils, to choose the least, which is claret. Its percentage of alcohol is small, and it contains tannin, which is still regarded by some as of medicinal value. Beers are considered more injurious than wines. The composition of wines is involved in some obscurity, but they certainly do not contain the salicylic acid and cocculus indicus which have been found in some beers.

Having mentioned some of the substances to be avoided in the diet of those afflicted with Bright's disease, it remains to be stated what things may be consumed, not only with impunity but with benefit. The main reliance should be upon milk. An exclusive milk diet is often talked about but seldom lived up to. The bulk of this liquid, which must be taken to supply the barest needs of the system, is so great as to overtax the average healthy stomach, to say nothing of the irritable stomach of Bright's disease. According to Voit, a

healthy adult prisoner, while idle, requires 85 grammes of albumin, 30 grammes of fat, and 300 grammes of hydrocarbons per diem, while two litres (about 3½ pints) of milk contain only from 68 to 70 grammes of albumin. The fat in this amount of milk will be twice as much as is necessary, and the hydrocarbons about one-third the necessary amount. If the digestion is good the milk may be given unskimmed, as the fat may supply the deficiency in hydrocarbons, but if, as is generally the case, it is bad, the milk must be skimmed and the deficit in hydrocarbons made up by the addition of bread, oat meal, corn meal, hominy, or rice. On such a diet the nutrition may be well maintained, especially if the patient does not take much exercise, and here let me insist on the important fact that a patient with Bright's disease should take little or no active exercise, for muscular activity by increasing arterial tension is always injurious. Passive exercise in the form of massage is all that should be indulged in. The functions of the skin may be maintained by occasional warm baths followed by vigorous friction, during which great care must be observed to avoid taking cold. The underclothing should be of wool the year round.

The question of the climatic treatment of Bright's disease has not received the attention it deserves. Above all things the climate recommended should be dry. A warm is to be preferred to a cold climate, but a cold dry climate is better than one that is warm and moist. It is probable that the early detection of Bright's disease and the removal of the patient to a suitable climate will be followed by at least as good results as have attended similar procedures in cases of phthisis. Pye-Smith mentions the case of a young man who was anæmic and œdematous, with casts in his urine and increased vascular tension, who was completely cured by a residence of one winter in Egypt, the only additional treatment being flannel, diet, and chalybeates.

The drugs employed in the treatment of chronic Bright's disease are administered with the view of mitigating the severity of the secondary symptoms. Of these, the one universally present is anæmia, which may be so great as to cause serious difficulty in determining whether or not it is primary. For example, Fagge mentions a case of contracted kidney which was "set down," presumably by himself, as one of pernicious anæmia. The difficulty is enhanced by the fact that in high degrees of anæmia, owing to diminished blood pressure and malnutrition of the renal epithelium, a slight degree of albuminuria is frequently present. As to the degree of the anæmia of Bright's disease, that, of course, depends to a great extent upon the stage it has reached, although the anæmia in an early stage of cases that have been neglected may be greater than that of a later stage of cases which have received proper treatment. Chalybeates are, therefore, indicated from the start, a fact which was empirically ascertained long before the introduction of clinical examinations of the blood. There is no better preparation of iron in Bright's disease than the tincture of the chloride. Basham's mixture, which, besides this tincture, contains acetic acid and liquor ammoniæ acetatis, is an excellent preparation. The last-named drug is of value on account of its diaphoretic properties, and its administration has been a matter of routine at Guy's Hospital since the time of Addison.

Another diaphoretic has hardly fulfilled the expectations that were formed regarding it on its first introduction. I refer to jaborandi, and its alkaloid, pilocarpine. It is depressing in its action on the entire system, and is sure to interfere with the digestive functions. It should, therefore, be held in reserve for cases of rapidly progressing œdema, and then administered with care. It is best given hypodermatically, beginning with one-sixth of a grain of the nitrate of pilocarpine; next best by the mouth, in the form of the fluid extract. The infusion is very nauseating, and has not been prescribed by me for several years.

Purgatives are of great value in Bright's disease, and should be administered twice a week, even when the bowels are regular. The best cathartics are the salines, and of the salines there is none better than a mixture of magnesium sulphate and potassium bitartrate. A drachm of the former and half a drachm of the latter in lemon syrup and water is not unpalatable, and may be given every hour until several doses have been taken, or one single larger dose of the two may be given early in the morning in a glass of hot water. It is doubtful whether the saline and alkaline-saline waters so much employed in Germany in the treatment of Bright's disease possess any medicinal influence apart from their laxative properties. Mercurials should not be employed in the treatment of Bright's disease, as they are apt to induce salivation, and are besides contraindicated by the anæmia which is always present.

Another drug to be avoided, especially in that form of the disease associated with contracted kidney, is opium. Comparatively small doses of opium have caused narcotic poisoning in several instances. Intercurrent attacks of pain may, however, necessitate the use of this drug, but if morphia be used hypodermatically, it should always be combined with atropia. In acute Bright's disease this intolerance of opium is said not to exist, but it is hard to draw the line between acute and chronic. For instance, you may be called to attend a patient with an attack of acute Bright's disease, and this very attack may be engrafted upon a chronic process of which both yourself and the patient may be entirely ignorant.

The dyspnœa, which is often an alarming symptom of Bright's disease, is best combated with nitrite of amyl and nitroglycerine. The effect of the former is transient, that of the latter much more permanent. Great œdema of lower limbs and scrotum may be relieved by needle punctures, from which there will be a constant oozing of serum. These punctures may, however, be the starting-point of erysipelas or gangrene in late stages of the disease, and such complications are rapidly fatal.

The treatment of uræmic convulsions or coma, to be successful, must be vigorous. In case of violent clonic convulsions, venesection should be promptly resorted to, from ten to twenty ounces being abstracted from a vein. In case of coma a drastic or hydragogue purgative, such as elaterium or croton oil, should be administered, and of the two I prefer the latter. Two drops of croton oil in a little mucilage may rescue the patient from an apparently hopeless condition. The cardiac complications present the same indications as those of primary heart disease.

With the aid of the various measures above enumerated, life may often be prolonged for an indefinite period. Albumin and casts may be present for years in the urine of persons who present an appearance of robust health;

but it is scarcely necessary to say that such people have made a study of living under difficulties, and are aware that the slightest indiscretion may prove fatal.

THE COTTAGE PLAN OF TREATING CONSUMPTION IN COLORADO.[1]

BY SAMUEL A. FISK, A.M., M.D.,
OF DENVER, COLORADO;
PRESIDENT OF THE COLORADO STATE MEDICAL SOCIETY; PROFESSOR IN THE UNIVERSITY OF DENVER.

IT is well, I think, to recall every once in a while the fact of the prevalence of phthisis. In a general way it is recognized that it is a dread disease, the cause of many deaths, and, until recently, it has been considered incurable. One is almost appalled, however, when he comes to investigate the facts. It seems nearly incomprehensible that about 100,000 lives are lost annually in the United States alone through this fell complaint, and that in general it is the direct cause of twelve per cent. of all mortality, and that in many cities this percentage runs up to even twenty per centum of all deaths.

Since the days when smallpox created such frightful ravages, which happily are now done away with by proper sanitary measures and by the introduction of vaccination, pulmonary consumption has become the dread foe of mankind, the insatiate minotaur of disease.

The accustomed, the every-day event, is apt to attract but little attention. It is the unaccustomed that is noticed. So when Spain loses 100,000 of her population by an epidemic of cholera, the world is struck dumb with fear and sorrow. The annual loss of an equal number of lives in our own country, by a disease more insidious and quite as fatal, passes without comment.

The reason for this may be that we feel ourselves, in a measure, helpless. We know not which way to turn to prevent. The introduction of the germ theory and the demonstration of the bacillus has not aided us much. Deep inhalations, the pneumatic cabinet, deep injections, creasote, iodine, carbolic acid, inflation with hydrogen sulphide, and all other means of treatment have not been of much avail. They have not sensibly diminished the death-rate.

To-day the best accepted plan of treatment is the climatic, the application of atmospheric and telluric influences to this diseased condition.

Undoubtedly different manifestations of the disease require different kinds of climate. It would not be proper, for instance, to subject an advanced case of laryngeal phthisis to the rigorous climates that many cases of incipient phthisis can stand, nor to place an enfeebled person, with bad digestion and poor powers of reaction, where his system would be still further enfeebled rather than built up.

Dr. Knight, of Boston, in an able paper read before the Society for Medical Observation a year ago, has very ably summarized the ideas of the profession, or perhaps I should say those ideas most generally held, with reference to the selection of a climate for patients with pulmonary tuberculosis, and, inasmuch as they are the opinions held by Hermann Weber, Lindsay, and others, I will venture to state them briefly.

The first object to be attained, he writes, is an out-of-door life in a pure air, the chief good coming through the general improvement in nutrition, and this reaches its maximum benefit when the patient can lead an active out-of-door life at considerable elevation (4,000 to 8,000 feet above the sea-level). He then proceeds to say that "There seems little doubt that in suitable cases the improvement in nutritive activity is much more marked in mountainous regions than on the plains," the reasons being (1) rarefied air; (2) dry and pure air; (3) the large number of clear days when the invalid can be out of doors.

In the main, the cases that can expect a benefit from the climates of high elevations are the incipient cases, those cases more advanced, but without excavations and not having any serious constitutional disturbance; the hemorrhagic, fibroid conditions, when the patient is young and the heart not enlarged, and those recovering from pleurisy or pneumonia, in whom the irruption of tubercle is feared. With reference to high altitudes he remarks: "The region which I have found best for this kind of treatment is the eastern slope of the Rocky Mountains, in the States of Colorado and New Mexico, where the altitude ranges from 4,000 to 8,000 feet."

Such, then, is the opinion of one of the recognized leaders in this particular branch of medicine in this country, an opinion which is meeting with constantly increasing acceptance. Across the water the same ideas exist with reference to high-altitude cures, and they find expression in a recent utterance of Sir Andrew Clark: "I am as sure as I can be about anything at present, incapable of actual demonstration, that the recoveries from phthisis judiciously treated at high altitudes, are much more numerous and much more lasting than those treated by any other method at any other place."

I trust that the Society will pardon me this introduction to what I wish to present as the main idea for the discussion this evening. I have made it because I wish to emphasize the fact that we have in our climate those conditions which experience has shown, and which the profession are learning to recognize, conduce to more numerous and more lasting cures from phthisis than those treated by any other method. We have conditions favorable for out-of-

[1] Read before the Denver Medical Association, etc., March 7, 1889.

door life in an elevated region. We have the dry and pure air, and a percentage of sunshine that is almost unrivalled. We can point with pride to a close analysis of our meteorological data, and square them by the crucial tests proposed by Franklin, Weber, Tucker Wise, and others for the desirable climatic elements in the treatment of phthisis, and find them in no whit wanting. There are those among us who have spent no little time and effort in calling the attention of the profession, and of the public, too, to these climatic conditions, and to their efficacy in the arrest and cure of pulmonary disease. But we must not rest here; we should learn to take advantage of all that modern investigation has proved to be of avail in the proper treatment of phthisis and superimpose it upon the benefits to be derived from our climate.

"The author will have written to little purpose," says Dr. Lindsay, "if he has not shown that climate *per se* is not the exclusive agent in the case, and that to rely upon it alone, to the exclusion of its indirect influence upon life and habit, is to invite failure."

"Wherever the patient goes he should, if possible," writes Dr. Knight, "consult some good physician of the region, who will lay out a plan of life. Many patients make themselves sick, and even destroy their chances of recovery, by neglecting to consult a local authority for this purpose."

"I have already allûded to the circumstance," are the words of Dr. Hermann Weber, "that intelligence on the part of the patient and his friends is a great help toward recovery in phthisis, and that want of judgment into the nature of the illness, and of the manifold dangers, and into the means of cure, renders the prognosis less hopeful, unless we are able to place the patient under the strictest superintendence of a judicious doctor, etc."

I have introduced these quotations because they voice what has probably been the experience of every one here, that people coming here and attempting to look after themselves, without medical advice, do not, as a rule, reap the best that is to be gained from our climate; and that very generally they make some grievous mistake which costs them so severely in point of health that they die, or go away disgusted saying that the climate is not what it is cracked up to be.

A climate, like any therapeutic measure, has to be used discreetly to obtain the best that can be gained from it, and this can be attained in the best way from consulting those who have had experience in it. Not only does it require a knowledge of the climate to treat a phthisical patient properly, but the practitioner, to be well equipped, should have had an experience in handling such cases, so as to know how to give directions into the minutest details of the regulation of the patient's life.

I know of no disease that requires such careful handling as that of phthisis. The treatment is somewhat concerned with the administration of drugs, but only to a slight extent in comparison with the attention that has to be given to the regulation of diet, exercise, clothing, the proper attention to all functions, the ventilation of the rooms, the regulation of the hours of sleep—in fact, the regulating of the invalid's life.

Many think that such details can only be carried out by putting the patient under the very closest surveillance, and for this purpose sanatoria have been erected at which phthisical patients are gathered, and in which their lives are regulated to a nicety, the whole institution being run on a system with almost clock-like precision. The two most noted of these sanatoria are those of Dr. Hermann Brehmer, at Gôrbesdorf (elevation 1740 feet), and of Dr. Dettweiler, at Falkenstein (elevation 1500 feet).

The attention of the profession in America has recently been called to the two systems by two excellent articles from the pen of my friend, Dr. Kretzschmar, of Brooklyn, and they have, further, the endorsement of Dr. Hermann Weber, to the effect that "the results obtained at this establishment show how much can be done in phthisis by carefully arranged hygienic management, even with imperfect climatic elements."

It is worth our while to inquire whether some such system might not be introduced with advantage in our treatment of this disease, rather than to keep on pursuing the plan now in vogue—which, in contradistinction, I have called the cottage plan—which allows the invalid to be his own master, to live, always subject to direction, of course, but without surveillance, in a boarding-house, hotel, or at his own home.

I know that this plan has many disadvantages, and yet I am a strong believer in it. I know that in the matter of exercise, for instance, which should be regulated with great care, in accordance with the demands of the individual case, it is not always possible to get your patient to carry out instructions unless he be carefully watched. I have seen more harm done by over-exercise than by too little exercise. I can recall a case in which recovery was sacrificed to a fishing excursion of only a few hours' duration. I have in mind another case in which irreparable harm was done by too long a ride on horseback. I think a life in my practice was sacrificed by pitching quoits and swinging Indian-clubs after a fatiguing journey. I have seen imprudence in regard to tiring one's self in talking, singing, and keeping late hours, produce severe hemorrhages. I need not multiply examples; they will recur to each one of you. To be sure these results might have been avoided in a sanatorium where the patient would have been under guard; but such cases, after all, are few in comparison with the total of cases under treatment. The majority of patients will use due care, if the importance of the subject be presented to them, and it is possible, if such measures be necessary, to have the watch established and

conducted by the friends and family rather than by hirelings.

I will acknowledge, too, that it is of the utmost importance that the invalid should have the proper amount of out-of-door life, here again regulated to the demands of the particular case. If he be weak, it should be obtained by sitting or resting in the open air; if he be stronger, by moderate walking and driving; and, where he is able, by a life in the saddle.

But we in Colorado have not found it necessary to build sanatoria to carry out these ideas, and our results can attest our successes.

It is of the utmost importance that the strictest attention should be paid to the diet of the invalid. Undoubtedly this can be regulated to a fine point in a sanatorium. It may be necessary to cater to a capricious and whimsical appetite, or to have the food supplied frequently and in small amounts, all of which can be carried out in a sanatorium, as is done in the two I have mentioned.

But when this becomes absolutely necessary it can be done in one's home quite as well as in a sanatorium, and that is the plan followed in Colorado.

It is not necessary to go into all the details of the regulation of an invalid's life, which can undoubtedly be carried out to their fullest extent at some well-conducted institution. There are these very decided objections in my mind to such methods.

I think that it should never be lost sight of that the phthisical invalid is a human being, usually of mature years, who values his independence, who chafes under discipline of any sort, and who hates and detests being schooled again, or being huddled with other invalids like a flock of sheep.

It seems to me that enough attention has not been paid to the treatment of the mental states of phthisical patients. The *spes phthisica* has become proverbial, and it is spoken of off-hand as though, given a phthisical case, he must necessarily be hopeful, and therefore cheerful, a condition that he can no more help, and for which he is no more responsible, than a good Knox Presbyterian is for the sins that he was foreordained to commit.

This is by no means the case. He may be deceived as regards the seriousness of his condition, but he is by no means free from depression. He is rather fond of dwelling on his symptoms, of comparing notes with his fellow invalid. He watches too closely, if he be permitted to do so, his appetite, his digestion, the hours of sleep, his temperature, the amount of cough, and character and quantity of his expectoration.

He is easily depressed by a slight variation from the normal in any of these conditions, and is made very apprehensive by any ill that befalls another invalid, lest the like may soon come upon him. A death casts a gloom over the whole community, and produces a mental depression in a colony of invalids that has a serious effect upon their well-being.

Because of this infectiousness, because of their too great susceptibility to the blues, because grit and determination and a cheerful mental condition have a great part to play in effecting a recovery, I think it unadvisable to congregate invalids where their thoughts are constantly employed in comparing notes with fellow invalids, and where they are subjected to the depressing influences that necessarily surround disease.

Again, all authorities agree now-a-days that an aseptic air is a prime essential in effecting a cure. I need not run over the writers to prove this fact. It is a well-recognized principle, and can be summed up in the words of Dr. Hermann Weber: "Hence it is clear that *purity* or an *aseptic state* of the air is the first demand which we ought to make on the climates to which we send persons affected with phthisis;" and then later on he writes: "*Purity* or *aseptic quality of the air is incompatible with the crowding together of a large number of invalids.*"

This is, it seems to me, a positive objection to the sanatoria, that by crowding the invalids together they render an air aseptic in itself very foul and septic. So well recognized is this that great pains are taken at most sanatoria to produce good ventilation.

But no better precautions can be taken, it seems to me, than to isolate such cases from each other.

I must confess that it strikes me as somewhat absurd to advocate the absolute necessity for a pure, aseptic atmosphere, and then to constantly subject the patient to septic influences.

Dr. Geddings, of Aiken, in a recent paper, writes: "The physician in search of a health resort for his phthisical patient wishes to know, above all things, the extent to which the air of the place proposed is aseptic." Later, in the very same paper, which is a strong plea for the desirability of Aiken as a health resort because of its possessing an aseptic atmosphere, he writes:

"For a number of years I have resided near a large hotel which, during the winter, is frequented by a number of consumptives in every stage of their disease. These people, in expectorating, not infrequently miss the spittoon, and the muco-purulent sputa reach the carpet-covered floor. Others, again, use their pocket-handkerchiefs as cuspidors, or, as I have seen them do, they spread over the bed a large newspaper for that purpose, preserving it until the physician makes his visit in order that he may see the amount and character of the expectoration. Thus, even when not deposited upon the floor in the first instance, the sputum dries and portions of it, after being diffused through the atmosphere of the rooms, eventually settle upon the carpet. Then, mixed with dust, the bacilli are frequently stirred up by sweeping, but, in obedience to the laws of gravity, soon return to their resting-place on the carpets.

This goes on for months; day after day, week after week, the process is repeated, and it would be difficult to devise a better method of making a wholesale collection of tubercle bacilli."

We accept the doctor's statement, and believe that his conclusion is correct. It would be difficult to devise a better method of making a wholesale collection of tubercle bacilli.

Inasmuch as he also tells us that this large hotel is frequented by consumptives who have gone to Aiken under the advice of physicians, because its air is so thoroughly aseptic, we congratulate them on having attained their object so thoroughly.

But, leaving now the general discussion, I must hasten to summarize my ideas.

I am a firm believer, from years of experience and on theoretical grounds, in the efficacy of the Colorado climate in the arrest of a large number of cases of pulmonary tuberculosis of the types mentioned by Drs. Knight and Lindsay. I believe that the best results are obtained under the advice and careful supervision of a competent physician on the spot. I do not believe in congregating invalids, quite as much because of the dread of mental contamination as because of the exposure to septic influences.

I am convinced that good results are only to be obtained by paying strict attention to the minutest details in each individual case in regard to the diet, exercise, sleep, ventilation, clothing, the several functions of the body—in fact, by a close watch over a patient's daily life.

I know that this can be done, as it is now being carried out in Denver, Colorado Springs, Manitou, and other places in Colorado, by permitting the invalid to live a home life, in his own house or one that he rents, with his family; or, where such surroundings are not possible, in a well-selected boarding-house.

There are objections at times to this method. The physician does not invariably have the absolute control of his patient that he would have were the case placed under strict surveillance in an institution for such cases, and bad results do occur, as I presume they do even at Görbesdorf or Falkenstein. But, gentlemen, I have been a consumptive invalid myself, and many of you have also been in the same condition yourselves, and I appeal to you, if you do not feel with me, that as a consumptive you would rather live as a man, under the plan pursued in Colorado, than be caged with a crowd of hollow-coughing consumptives in any sanatorium, even though it might have the covered walks and the winter garden, suitably warmed and ventilated, of Görbesdorf itself.

One objection is frequently made to Colorado as a resort, and that is that it is no place for a poor man.

Unfortunately this is true. The expense of getting here is great, and the cost of living after one reaches here is considerable. It is to be doubted, however, if the erection of sanatoria would materially help affairs. To be properly conducted they are expensive, and Dr. Kretzschmar says of Dr. Dettweiler's establishment at Falkenstein that the expenses amount to not over twelve marks or three dollars a day, a condition of affairs which would certainly not help a poor man very much, and a daily expense which would enable any one to live very comfortably in Colorado.

SUDDEN DEATH IN TYPHOID FEVER.

BY A. McPHEDRAN, M.B.,
LECTURER IN CLINICAL MEDICINE, UNIVERSITY OF TORONTO, ETC.

IN connection with an editorial on this subject in THE MEDICAL NEWS of February 15, 1888, this case will prove of interest. The following notes of the history are abstracted from my hospital case-book.

Thos. M., aged thirty-two, laborer, was admitted to the Toronto General Hospital, December 11, 1888. He said he had been ill one week before entering. His temperature was 105° F., and he seemed very ill for so early a period in the disease; this was probably due to the disturbance incident to his removal to the hospital—he came from one of the suburbs, a distance of six miles. A few days later the symptoms moderated and presented those of an ordinary attack of typhoid fever. He continued to do well, and on December 20th his temperature was 102°, pulse 100, regular and of good volume and tension; taking plenty of nourishment; sleeping well; urine normal; no diarrhœa.

December 21. His condition was reported by Dr. T. P. Weir, my house physician, as quite satisfactory, pulse being even stronger.

December 22. 1 A. M. Seen by Dr. Weir, who made a special visit to the ward on account of a change of nurses. Sleeping quietly. A few minutes later he asked the nurse, who was attending a patient in the next bed, for a drink, which was given without his making any movement. A minute or two later she noticed that his breathing was distressed. He moved his arms about and seemed to be conscious. Before Dr. Weir, who was summoned, could reach him he was dead.

Post-mortem.—Ulcers in lowest twenty inches of ileum indicated the end of the second week of the disease. Mesenteric gland near ileo-colic valve very large and diffluent. Solitary glands in cæcum, ascending and transverse colon enlarged but not ulcerated. Kidneys healthy. Lungs: some old pleuritic adhesions; slight œdema at apex of right; some venous congestion of both posteriorly, probably post-mortem. Heart: right auricle greatly distended with recent black clot; right ventricle considerably distended; left side of heart contained a little blood, ventricular wall not contracted. Brain was not examined.

The symptoms attending death in the foregoing case indicate cardio-respiratory failure as the cause of death and as no adequate cause of death was to be found in the lungs the cause must be attributed to heart failure. The symptoms were not compatible with a cerebral cause. The tissue of the heart was firm and showed no histological change to account for such failure. There were no evidences of the existence of such causes of sudden death in typhoid fever as hemorrhage, embolism, uræmia or overwhelming typhoid toxæmia. The only cause suggested in the aforesaid article in THE MEDICAL NEWS having even a possible connection is special localization of the infecting principle upon the pneumogastric nerves. That such localization ever occurs is only a theory incapable of proof; the probability of its being true is, to say the least, doubtful. It is difficult to understand how a poison that is depressing in all the other manifestations of its effects could in this instance act as a stimulant and so excite the vagus centre as suddenly to arrest the heart's action in diastole.

A much more probable theory is given in a most interesting and valuable paper lately published by Prof. John McWilliam, of the University of Aberdeen, on "Cardiac Failure and Sudden Death."[1] He says that

"A long series of experiments on the mammalian heart has convinced me that in ordinary circumstances sudden cardiac failure does not usually take the form of a simple ventricular standstill in diastole. . . . . It assumes, on the contrary, the form of violent, though irregular and incoördinated, manifestation of ventricular energy. Instead of quiescence, there is tumultuous activity, irregular in its character and wholly ineffective as regards its results. . . . . The muscular action partakes of the nature of an arhythmic, incoördinated, and rapidly repeated contraction of the various muscular bundles. Some bundles are in a state of contraction while other bundles are relaxed, and instead of a coördinated contraction leading to a definite narrowing of the ventricular cavity, there occurs an irregular and complicated arhythmic oscillation of the ventricular walls which remain in a position of diastole."

He points out that the susceptibility of the heart to be thrown into this state of "delirium" is increased by any conditions that interfere with its normal nutrition, as, for example, in the course of prolonged experiments in which "the nutrition of the heart is altered and impaired, its irritability is markedly exaggerated and the tissue has passed into a state of unstable equilibrium." The heart being in this condition of unstable equilibrium very slight causes may suffice to throw it into this state of irregular fibrillar mode of contraction—or "delirium cordis;" as, for instance, the gentlest handling or even a touch with the tip of the finger. And not only so, this state of delirium not infrequently develops spontaneously and without the intervention of any apparent irritant or immediate disturbing agency.

In the light of these facts there seems little room for doubt that the nutrition of the heart is so altered in all depressing diseases, especially in typhoid fever and diphtheria, as to render it very liable to be thrown into "delirium," and this derangement of the heart's action probably occurs in all cases of sudden death in these diseases.

RIGHT-SIDED APHASIA IN A LEFT-HANDED PERSON.

BY H. C. WOOD, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS AND CLINICAL PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM IN THE UNIVERSITY OF PENNSYLVANIA.

THE following case has seemed to me worthy of being recorded on account of the curious relations between the habitual use of the hands and the speech function. On reading the record taken from my note books, it will be seen that the aphasia was the result of a lesion in the left side of the brain. Although the person was for the ordinary purposes of life left-handed, he had always written with the right hand; the centres connected with writing, in locating themselves, so to speak, had followed not the centres of habitual physical action, but the centres of speech function. In other words, this man possessed a brain in which the speech centres were highly developed in the left hemisphere, although the motor centres for the hand and leg, and probably for the face, were more highly developed in the right than in the left hemisphere, and in which when the art of writing was learned, the motor centres of the left hemisphere underwent special development, apparently on account of their close relations with the centres of speech.

Mr. S. B. K., was brought to my office by Dr. E. N. Musser of Mechanicsburg, Pa., with the following history. A retired merchant of about fifty, he was in good health until the 10th of September 1888, except that for several days he had complained of numbness of the right side, especially of the fingers; although examination by Dr. Musser failed to detect any loss of sensation in the arm. On the day mentioned, while telling a story, he suddenly lost the thread of his narrative and after a moment's silence, said to a friend, "There is something the matter with me." On attempting to walk, he found that locomotion was impaired; but leaning on his friend's arm he finally reached home. When Dr. Musser saw him he could not walk alone at all with his eyes open, although with assistance he could. "When his eyes were closed, could not take a step." He could move his hands and feet, but in walking had a distinctly ataxic gait. There was no headache; no convulsive movements; no loss of consciousness. The aphasia gradually increased, and

by the end of the week it was almost complete. It was also accompanied, Dr. Musser thought, by progressive loss of mental power.

The following I take directly from my note book. "The patient is evidently left-handed. Dr. Musser states that he has always used the cane, saw or hatchet with the left hand. In my office he uses the scissors perfectly well with his left hand, but he writes, as he always has done, with his right hand. The left pupil is a little larger than the right; the left grip 100, the right 90; station on both feet good; can stand distinctly steadier on the left than on the right leg, but station is not much affected by shutting the eyes. In walking he drags his right toes; when he walks with his eyes shut, does so with evident difficulty, staggers and seems about to fall, although he recovers himself. The knee-jerk on the left side is apparently a little more active than on the right leg; there is distinct loss of sensation of the right hand, and a slighter loss in the right foot; there is no alteration of the optic disks, and an attempted examination of the visual field failed on account of the patient becoming very excited so that it was utterly impossible to make him understand, or to get him to do what was wanted. He hears the watch on the right side about three inches, on the left side not more than five or six inches. There is no distinct facial palsy.

The patient's intellectual powers are evidently much affected, it being very difficult to get him to understand what is wanted. The aphasia is very pronounced, but not absolutely complete. He formerly talked German fairly well, but at present uses no German except one or two words; seems to understand questions much less readily than when addressed to him in English. The following questions and answers give a fair idea of his aphasic condition. "How long have you been sick?" "Twill tim t-t twill till." "Have you headache?" "Yes, sir." "Where?" "I-I have t-will it t-twill l-leav pal north till or nor." "Can you read?" "Yes, sir." (Reads.) "Meri can ant only can't see at does lesanteen an und max, l-tel neville." In answer to the question if he went to bed by himself, he commenced to make signs of undressing. When asked what time it was, he looked at his watch and said, "warter of three," it being twenty minutes of three, and he evidently seeing that the hand was at twenty minutes and near the quarter, and not being able to say "twenty minutes," did the best that he could. When asked to write his name and address, wrote his name legibly, then the address illegibly; and when asked to write some words, was unable to do so at all.

HÆMATOMA OF THE SEPTUM NARIUM.[1]

BY MAX THORNER, M.D.,
OF CINCINNATI, OHIO.

C. H. S., German, tailor, consulted me about eight weeks ago in reference to an obstruction of both nostrils. He had been under my care during last summer for nasal polypi, which had been successfully removed. He attributed the present trouble to a "cold," or the possible recurrence of the polypi. Upon examination I found that both nostrils were entirely obstructed by a tumefaction on both sides of the cartilaginous septum, which, touching the inferior turbinated bones, rendered nasal respiration well-nigh impossible. The swelling, which was distinctly fusiform, appeared to be covered by a purplish-red, glistening mucous membrane; it was not sensitive to the touch, and yielded readily to pressure with the probe.

Since there had never been any evidence of this tumor in the patient's nose during his former treatment, I elicited upon further inquiry the following history from him:

About a week previous to this consultation he happened to come home in a wagon, and arriving at a door in the rear of his home, jumped down hastily on to the door steps. At this very moment his wife, who had been awaiting him, suddenly opened the door, which opened outward, and he was struck very forcibly by the door on his nose. He, however, did not pay any attention to this accident, there being a slight hemorrhage only, whilst the pain produced by the injury, though intense in the beginning, subsequently subsided within a short time.

For that reason, a few days later, when he first noticed the obstruction of his nose, he did not attribute it to the sustained contusion, but simply charged it on the much-abused and popular etiological factor of "having caught a cold."

I made an incision into the tumefaction, on the left side, with a curved bistoury. About a drachm of blood having escaped, the tumor on both sides of the septum flattened, and the mucous membrane lay close to the cartilage. When I saw the patient the next day the sac had partially filled again. But this time he refused another incision, in order to try first some home remedies. Three days later the swelling was as large as in the beginning. In spite of my urgent advice to have another incision made, the patient insisted upon continuing poulticing his nose, which, according to popular belief, would reduce the swelling without resorting to knives.

He reappeared, three days later, in a somewhat altered condition. The last days he had felt miserable, had had several chills, had been unable to sleep, and had the most intense pain in his whole head. He complained also of loss of appetite, and of pain in his eyes. The latter presented chemosis of the conjunctiva, epiphora, and œdema of the lower lids. The swelling on both sides of the septum had increased, the mucous membrane covering the same was crimson, and fluctuation from one nostril to the other was very distinct. There was no doubt that pus had formed, and that we had now to deal with an abscess instead of a hæmatoma. By two long incisions across the bulging swelling on both sides of the septum, a considerable amount of pus was evacuated. In the middle of the cartilaginous septum was a perforation the size of a small bean. The probe could be introduced about one inch backward, and touched the denuded vomer.

[1] Read before the Cincinnati Medical Society, February 12, 1889.

After-treatment consisted in tamponing the abscess cavity with iodoform gauze, repeated every day; and in three weeks the cavity had closed, leaving only a small perforation in the cartilaginous septum. There remained, however, around this perforation, and especially near the floor of the right nasal fossa, a solid thickening on the septum, representing, no doubt, an ecchondrosis, due to a simultaneous perichondritis.

Hæmatoma of the septum narium is not a frequent occurrence. A great many text-books do not mention it at all. According to Sir Morell Mackenzie, it is nearly always caused by direct injuries to the nose. An extravasation of blood between the deeper layers of the mucous membrane and the cartilage takes place; and the septum mostly being fractured, the escaped blood assumes the shape of a bilateral tumor on both sides of the septum. Morell Mackenzie, however, mentions two cases of spontaneous, unilateral hæmatoma of the nasal septum. If the blood be not absorbed readily, which is not probable, surgical measures must be resorted to; otherwise there will soon be purulent degeneration of the contents of the sac, as occurred in my case.

The diagnosis is easily to be made: the history of a previous traumatism, the sudden development of a bilateral, symmetrical tumor, the physical condition of the same, the absence of pain and fever, and, eventually, in doubtful cases, the aspiration of the contents with the exploring needle, will settle any doubt regarding the nature of the tumefaction.

In conclusion, I wish to call attention to the fact that, as it was the case with my patient, there remains mostly a perforation in the septum. The latter has been regarded, and is sometimes still looked upon, as a pathognomonic sign of a specific infection. On a former occasion I have tried to show how little we can depend upon the presence of a perforation in the nasal septum alone for the diagnosis of syphilis.

I have seen a number of such perforations, where syphilis could be excluded with certainty, although I fully agree with J. Solis-Cohen, when he says: "The probability is, in at least a fair proportion of instances, that the perforation has resulted during the course of a syphilitic coryza, which has occurred in early infancy." (*Diseases of the Throat and Nasal Passages*, 2d ed.) Yet there is a variety of other circumstances that may produce perforations: as in the reported case, hæmatoma or abscess of the septum, or operations performed upon the same. We find, furthermore, perforations as sequelæ of scrofulous or tubercular affections, of phlegmonous inflammations, and of lupus of the nose. They have been observed following variola and typhoid fever, and they are found occasionally in chronic rhinitis, especially in the atrophic form. Also the bad habit of removing, with the finger-nail, crusts and scabs adhering to erosions of the septum has frequently resulted in perforations. And according to Carl Seiler (*Diseases of the Throat, Nose, and Naso-Pharynx*, 3d ed.), they are said to be always present in workmen employed in bichromate of potash works.

354 W. EIGHTH ST., CINCINNATI.

HOSPITAL NOTES.

MATERNITY HOSPITAL OF PHILADELPHIA.

SERVICE OF BARTON COOKE HIRST, M.D.

HÆMATURIA IN PREGNANCY.

This is a subject which receives almost no attention in current works on obstetrics, and yet blood in the urine is a symptom of not such very rare occurrence in the pregnant woman, and is one, moreover, that always excites the alarm of a patient and those interested in her, and may cause the attending physician some anxiety.

M. S., primigravida, aged twenty-six years. When about six months pregnant she first noticed that her urine was bloody; the hæmaturia appeared suddenly, and to as great a degree as it has since attained. There is no history of malarial infection. There have been no intervals in which the urine was clear; at every micturition there has been a considerable quantity of blood mixed with the urine. There is no history of traumatism. As long as the patient can remember she has suffered pain over the region of the kidneys, which, at intervals, has become quite intense, shooting down along the course of the ureters. Since the appearance of the hæmaturia there has been some difficulty in urination; the flow is suddenly stopped, apparently by the lodgement of a small clot in the urethra; as soon as this is expelled the stream again becomes free. This condition persisted until the delivery of the infant. On the second day of the puerperium the quantity of blood was much diminished; on the third day it had quite disappeared, and there is now, nine days post-partum, no trace of it.

The explanation of this case, as of the majority in which bloody urine appears during pregnancy, is very likely to be found in bleeding hemorrhoids of the bladder, produced by the pressure of the large gravid womb upon the pelvic veins.

There were symptoms pointing to the possibility of an impacted renal calculus, but the absence of acute pain while the patient was under our observation; the sudden onset of the hæmaturia when the uterus had reached a size to exert pressure upon the pelvic organs; the rapid disappearance of the blood as soon as this mechanical obstruction was, in great part, removed, all point to the hemorrhoidal origin of the hemorrhage.

The treatment of such a case can be little more than expectant until pregnancy is terminated, unless—a rare event—the quantity of blood lost is alarming.

MEDICAL PROGRESS.

The Treatment of Ileus.—DR. GOLTDAMMER recently delivered an address on ileus before the Berlin Medical Society. It was based on fifty observations (thirty men and twenty women). Thirty-five of the whole number

died and fifteen were cured. With regard to the fundamental condition accurate statements could be made in thirty-eight cases. In ten cases there was carcinoma of the colon; in seven invagination; in six the cause of the ileus was found to be kinking of the coils of the small intestine, owing to circumscribed peritonitis; in five it was old cicatricial stricture; in four volvulus; in two tubercular peritonitis; in two internal incarceration. In one, in which the patient was moribund when admitted, the cause was reduction of a hernia *en masse*, and in one a gall-stone impacted in the small intestine. In all the malignant cases it was the large intestine that was affected. Rectal cancers were not included. In only two of the ten cases could a tumor be felt in the region of the sigmoid flexure. The seat of the stricture could never be reached from the rectum. In one of these cases the patient was a girl, aged twenty-five; in another, a man, aged twenty-six. Of the other cases of chronic stricture of the gut there were four of the old cicatricial stricture of the large and one of the small intestine. In two cases tubercular peritonitis had led to the matting together of the coils of small intestine and of their adhesion to the abdominal walls, and hence to strangulation. Of the intussusception cases the affected part was in one the descending colon; in three the small intestine; in two there was invagination of the ileum into the colon; whilst one case remained doubtful. In three of these cases a distinct tumor could be felt. In six cases death occurred after a duration of from four to eight weeks; one case recovered. The volvulus cases as well as those of internal strangulation all ended fatally in a few days. The treatment was confined to two things: the exhibition of opium in large doses and rigorous diet. The beneficial effect of opium on the acute symptoms of intestinal occlusion is well known. For this purpose it should be administered in the largest doses till contraction of the pupil, or less frequently, sleep is induced. If the opium cannot be kept on the stomach, morphine must be given hypodermatically. Injections of water or inflation with air should next be tried. In chronic obstruction a slow passage of feces may occur when, owing to the stoppage of peristalic action, the pressure of additional feces from above against the strictured point is arrested. Of the acute forms of stricture, intussusception is unquestionably benefited by opium. In these cases the imprisoned gut may spontaneously become released. One is often told by such patients that they have had similar attacks before. Every stimulation of peristaltic movement increases the constriction of the invaginated portion of intestine. The same holds good with regard to volvulus and internal strangulation. Here also arrest of peristalsis mostly prevents further filling of the intestine, and makes relief of the obstruction possible. For the release of the upper intestinal segment the application of the stomach-pump and puncture of the distended gut should also be tried. Together with the opium treatment, the strictest diet must be prescribed. Only small pieces of ice should be swallowed; nutrient enemata must be given. When complete rest of the bowels has been induced one to three litres of water should be injected with moderate force once or twice a day. By this plan of treatment Dr. Goltdammer succeeded in curing fifteen out of the fifty cases. From this he inferred that it is premature to look upon operative interference as the only remedy in ileus. The ten cases of cancer and the five of old cicatricial stricture afforded no hope of success from operation. In fifteen other cases it might, perhaps, on the whole, be conceded that timely surgical intervention offered a moderately good prospect.

With regard to the question why in these cases no operation was attempted, Dr. Goltdammer reminded his hearers that during life it was impossible to make a precise diagnosis. From this difficulty of diagnosis, and from the fact that a considerable number of patients recovered without operation, he argued that the field of preliminary laparotomy ought not to be extended. As regards diagnosis, it was perhaps possible to divide cases into two groups—namely, chronic mechanical obstruction of the lower part of the intestine, and acute internal strangulation and intussusception. But even this distinction is often not possible in particular cases. Moreover, the complication with peritonitis involves great difficulties; even coprostasis cannot always be excluded under the circumstances. A number of accurately recorded cases serve to prove that a favorable turn may often take place at a very late period of the illness. In addition to this, laparotomy is a dangerous operation. Patients suffering from ileus seem to bear the operation very badly, in spite of all antiseptics. Collapse and weakness of the heart's action are usually very marked. The peritoneum is, as a rule, not in a normal state, and, therefore, reacts differently from a healthy membrane. Unexpected difficulties are also often met with in operating. Dr. Goltdammer quoted instances exemplifying this.

Setting aside cases in which ileus depends on a hernia, preliminary laparotomy must, he said, be limited to (1) cases in which intussusception is recognized—the condition of which is most readily diagnosed with any certainty. The youth of the patient, suddenness of onset, absence of meteorism, loose and bloody stools, tenesmus, with the presence of a tumor of characteristic shape, will enable the experienced to make a diagnosis. (2) Cases in which, after an acute onset, and in spite of energetic treatment with opium, severe symptoms of obstruction and collapse persist, so as to give rise to the suspicion of acute internal strangulation. In both these cases laparotomy should be determined upon early. (3) The operation should be undertaken as a last resource in cases in which, after the subsidence of all symptoms under opium, severe symptoms set in anew. In these cases surgical interference may often be too late.

The discussion on Dr. Goltdammer's address took place at a later meeting of the Society on March 20th. Dr. Schlange took up a different standpoint from that of the lecturer, whose views he described as retrograde and opposed to the results of modern surgery. Even if the making of a precise diagnosis had to be postponed, a surgeon who operated in every case (the opening of the abdominal cavity being now free from danger) would not only have cured all the cases which had got well under Dr. Goltdammer's treatment, but would have rescued a much larger number at least from immediate death, even if the essential disease had continued to exist. Of course, laparotomy was practicable only before peritonitis had set in. All depended on an early diagnosis. He warned surgeons against operating in the later stages of the disease after the onset of peritonitis.

Dr. Fürbringer agreed essentially with Dr. Goltdammer's view, especially as regards the uncertainty of

diagnosis and the treatment, but he made more use of washing out the stomach and of injections high up into the intestine. Of the patients under his charge in his wards nearly two-thirds had died, while one-third had recovered, under this treatment. He called particular attention to one group of cases, which to a certain extent represented a distinct class; it was characterized by five marks: 1, stoppage of the bowels lasting from eight to fourteen days; 2, stercoraceous vomiting; 3, meteorism; 4, exudation which could be felt from the rectum; 5, atypical fever. These cases usually ended fatally from perityphlitic processes. Of such cases, which seemed almost hopeless, he had cured six by the treatment mentioned.

DR. KÜSTER entirely endorsed Dr. Goltdammer's suggestions. An operation must be performed in all cases of acute strangulation, especially reduction *en masse*, which could be diagnosed with certainty. Among the cases of slow development there was a group which was also open to diagnosis, namely, neoplasms, the presence of which could be recognized by a mucous discharge, which gradually became bloody. These cases called for enterostomy. For the bulk of other cases surgeons must first endeavor to obtain accurate means of diagnosis.

DR. SONNENBURG urged that surgeons should seek to determine the seat and nature of obstruction, and not rest contented with a general diagnosis of "ileus." Dr. Goltdammer had contributed nothing toward the elucidation of this important question. In the opium treatment there was danger that the feeling of comfort given by the drug might cause the favorable time for surgical interference to be lost. He referred to Von Wahl's method of inflating some segments of intestine as being possibly useful for diagnosis.

PROFESSOR SENATOR recalled an utterance of Professor Bardeleben in a previous discussion on this subject that people might, so long as the diagnosis was so uncertain, reasonably differ as to whether an operation was justifiable or necessary in such cases. For his own part he did not think the present discussion afforded grounds for an essentially different standpoint.

DR. LANDAU mentioned two cases of ileus caused by retro-uterine hæmatocele. Such cases were open both to diagnosis and operative treatment.

After DR. JACUSIEL had spoken in support of Dr. Goltdammer's views, the latter replied to the objections which had been brought against his statements and suggestions, which, he said, were based on existing circumstances, and were not intended to govern medical practice for all time to come.—*British Med. Journal*, April 13, 1889.

Treatment of Intestinal Hemorrhage in Typhoid Fever.—DR. LINDSAY, Physician to the Belfast Royal Hospital, in a paper on this subject in *The Dublin Journal of Medical Science*, April 1889, says that he has always been accustomed to follow Murchison's instructions, and has given tannic acid, laudanum, and turpentine, with ice externally and ergotin by hypodermatic injection. Some good authorities prefer to omit the turpentine, but he cannot say that he has ever seen any harm resulting from its use, and its power as a hæmostatic is undoubted. In one of his cases he gave laudanum pretty freely, in spite of the presence of albumin in the urine, and with good results—no sign of narcotism appearing. He is disposed to think that in intestinal hemorrhage, as in hæmatocele and other forms of internal bleeding, opium may be given fearlessly, and pushed even to heroic doses. Stimulants are certainly required in some cases, but must be regulated with much caution.

In conclusion, he says that while intestinal hemorrhage in typhoid fever is a serious symptom, it is by no means usually fatal, and prompt and decisive treatment is called for, and will often prove effectual.

Treatment of Hysterical Convulsive Cough.—

℞.—Powdered valerian root . 15 grains.
Powdered digitalis . . 1½ "
Powdered sugar . . 15 " —M.

Divide into ten powders. One to be taken every hour.

If the cough comes on during the menstrual period, and is accompanied with dysmenorrhœa, one teaspoonful of the following should be administered every two hours:

℞.—Carbonate of ammonium . 75 grains.
Tincture of opium . . 10 drops.
Decoction of yarrow . . 4 ounces.
Syrup of saffron . . . 1 ounce.—M.

—*L' Union Médicale*, March 24, 1889.

The Hot-air Treatment of Tuberculosis.—A supplement to the *Berliner klin. Wochenschr.* of March 11th contains a recent address by Professor Kohlschütter, on Weigert's hot-air treatment of pulmonary tuberculosis, given at a meeting of the Aerzte-Verein, in Halle, on February 20th. The fact that this treatment has already become a subject of comment by the newspaper world did not deter the speaker from examining the question scientifically. It is known that tubercle bacilli are peculiarly susceptible to influences of temperature; their vitality is lowered by a temperature of 101.3° F., and they are killed by a temperature of 107.6° F. To breathe hot air continuously for any length of time is impossible—only one of the speaker's patients could do so for as long as an hour—and the beneficial action of hot air in the above sense must be on the well-known principle of intermittent gradual sterilization, the germs being killed off in successive crops as they develop. Weigert, in attempting to apply this clinically, showed that extremely hot dry air can be breathed without injury. In Weigert's apparatus (which may be procured from A. Meissner, 71 Friedrichstrasse, Berlin), the thermometer shows a temperature between 480° and 570° F., and, although the air actually inspired is doubtless not so hot as this, it is hot enough to cause the expired air to have a temperature of 60° C. (140° F.). In a particular case of Professor Kohlschütter's the following effects were observed: in seven weeks after inhalation, twice daily, the chest-girth increased from 36 to 38 inches, and a pleuritic exudation in the left side was absorbed. Crepitation and dulness were replaced by normal physical signs, and good breath-sounds were heard over both lungs. Careful examinations of the sputa showed that the bacillary appearances were remarkably altered. At first the bacilli were numerous and more or less uniformly scattered; subsequently they were found only in groups of three or four, and were far fewer. At a later stage they had all but disappeared. The temperature of the body rises

about the third of a degree (F.) after each inhalation, but soon subsides. The pulse frequently showed a difference of only five, as counted before and after each inhalation. The respirations became deeper and slower; the patient in question—several others were treated—at last could do with seven respirations per minute; this is ascribed to the difficulty of inspiring through long tubes. The previous dyspnœa was lost, and more exercise could be taken. The cough at first increased a little, the expectoration considerably; but, at the date of the address, both were lost altogether. The bodily weight had increased from 73 to 73.57 kilos. (nearly two pounds). The author expresses himself as well satisfied with the results so far, and thinks this method of treatment worthy of more extended trial.

Salicylic Acid in Chronic Tuberculous Joint Disease.—DR. R. W. LOVETT, in a paper on this subject, published in the *Boston Medical and Surgical Journal* of April 11, 1889, reaches the following conclusions:

That salicylic acid in large doses is useful as an aid to the mechanical treatment of chronic tuberculous joint disease, not in routine conditions, but—

(1) When night cries are present.

(2) When the diseased joint is very painful and sensitive to jar.

(3) When vomiting and general discomfort are associated with an increase in the local disease.

That relief from pain, and diminished sensitiveness follow at once, as quickly as in acute articular rheumatism, and that the drug should be given in as large doses as for that affection until the pain is relieved or the physiological effect is produced.

Atrophy of the Optic Nerves Treated by Suspension.—DR. DARIER, at a meeting of the Société d'Ophtalmologie de Paris, held March 12, 1889, stated that the success obtained by Dr. Charcot from the suspension treatment of tabes had led him to try the same treatment in optic atrophy. The results surpassed all expectations. In all thus treated acuity of vision was greatly improved; one of the patients, who was nearly totally blind, being at present able to distinguish between objects. In two other patients acuity of vision was increased from one-sixth to one-third, and in still two others from one-quarter to one-half.

DR. ABADIE related the history of an eighteen-year-old patient, the sufferer from juvenile atrophy (his condition otherwise being good), in whom suspension wrought such changes that he was able to read, which he had not been able to do for six months.—*Wiener med. Presse*, March 31, 1889.

Treatment of Tuberculous Ulcers of the Tongue.—

℞.—Lactic acid . . . . . 80 parts.
Water . . . . . 20 " —M.

The affected parts to be touched several times daily with a camel's-hair brush previously immersed in this solution.—*Revue de Thérapeutique*, April 1, 1889.

Flute-player's Cramp.—A case of professional cramp in a flute-player was well described by DR. FÉRÉ at a recent meeting of the Société de Biologie. The patient was a habitual member of a theatrical company, to whom the flute was the only instrument allotted. He felt at first a paralysis in the extensors of the ring finger and little finger of each hand, and then a cramp in the opposing muscles which made him drop the instrument, sometimes with a cry of pain. Local massage and general tonic treatment brought him back again to a condition fit to resume his former work, though those of his audience with a finer ear than the rest could trace the effects of the cramp in the slightly slower time in which the notes played with the ring finger and little finger were given. Brown-Séquard took the opportunity to press the remark that in such cases of professional cramp the fatigue of the whole body was at least an equally essential component with the local strain. In a case of writer's cramp in a Cincinnati journalist, he had seen both feet as much affected as both hands after an excess of writing. (*Le Progrès Méd.*, 1889, p. 126.)—*The Practitioner*, April, 1889.

Trephining in Epilepsy.—The operation of trephining for traumatic epilepsy has been followed by some brilliant results, and there can be no question as to the justifiable nature of the procedure. The knowledge of the topography of the brain which has been brought within the reach of practical surgeons by the valuable researches of Ferrier and others has made it a comparatively easy matter to localize the exact seat of lesion in some, at least, of the cases of traumatic epilepsy. The patient conscious of the coming nerve storm, is often able to refer the onset to a certain part of a limb. This affords a valuable clew to the situation of the spot in the brain the nutrition of which is at fault. The consideration of these cases is always most interesting, and surgeons may well be proud of the success which has followed so important a procedure.

M. Péan, of the St. Louis Hospital in Paris, has just recorded an interesting case of epilepsy cured by the application of the trephine. The patient was suffering from slight epileptic seizures, the right side being mainly affected, and the lower limb more than the upper. During the intervals between the attacks, there was some paresis of the right leg. The diagnosis was made of a cerebral tumor, and its localization determined. The trephine was applied, and a fibro-lipoma was found attached to the pia mater. The growth was removed forthwith, but for some days after the operation the convulsive fits continued. Subsequently, however, they entirely ceased, and the patient became convalescent.

Homeriana for Tuberculosis.—DR. LASKOFF states in the *Allg. med. Ctrl. Ztg.* that he has successfully tried homeriana in the treatment of tuberculosis. This plant grows wild in Russia. Belonging to the order of Polygonaceæ, it contains an irritating oil, which, in fact, appears to be its foremost active principle. He administered this remedy in the form of an infusion, generally in affections of the respiratory passages, especially bronchitis and tuberculosis. Of 112 cases of tuberculosis treated with this remedy, he claims to have cured no less than 90; certainly a large number. The first symptoms of improvement observed were a fall of the temperature and a diminution in the expectoration. At the same time auscultation and percussion revealed marked improvement in the pulmonary symptoms.

In the more advanced stages of tuberculosis the action

of this drug diminishes, and although then unable to effect a cure, it still decreases markedly the night-sweats, cough, expectoration, etc.

The drug is administered in decoction or infusion made from one ounce of homeriana to two pints of water, which amount is to be taken during the twenty-four hours.—*Wiener med. Presse*, March 24, 1889.

Palpation of the Kidney.—DR. JAMES ISRAEL (*Berl. klin. Woch.*, No. 7, 1889) says that in palpating the kidneys one is apt to make the mistake of deviating too much laterally. If a line be drawn upward from the middle of Poupart's ligament parallel to the middle line, and the hand pressed deeply about two fingers' breadth below the point where this line intersects the costal margin, the normal kidney may be felt. It is important to have the abdominal muscles perfectly lax. Chloroform is useful, but has the disadvantage that we are unable to examine the organs in deep inspiration. It is also necessary to have the colon emptied.

Three methods may be adopted to palpate the kidney:

(1) *Bimanual palpation* in the dorsal position The patient is placed on a firm couch, the knees slightly bent over a pillow. If the right kidney is to be examined, the physician stands on the right side, places the left hand under the lumbar region and with the right presses from before backward, the middle finger being placed one inch below the junction of the tenth rib with the costal margin. Pressure is exerted during expiration, and is kept up continuously until the fingers reach the kidney. In this examination, very gently and slowly increasing pressure (always with the flat hand) is necessary. The points of the fingers should never be bent, as it leads to reflex contraction of the abdominal wall.

(2) *Guyon's method*—"*ballottement rénal*"—consists in the production of a rapid movement of the kidney from behind forward, so that the organ may be felt from the anterior abdominal wall. The position is the same as in the former method. While the patient is quietly and slowly breathing with open mouth, one hand laid flatly over the lumbar region gives short regular taps against the loins, so that the overlying kidney is moved forward against the other hand placed in front.

(3) When these two modes fail, a third often succeeds. Here the patient is in the lateral position. He lies on the opposite side with his legs flexed, breathing slowly and deeply with open mouth. With one hand behind, the lumbar region is pressed forward, the patient inspires deeply, pressure is applied from the anterior abdominal wall, and at the end of inspiration the organ may be felt in its lowest position. It is this movement which distinguishes it.

Israel maintains, in opposition to some other authorities, that normal as well as diseased kidneys, if not fixed by new growth, perceptibly move downward in most cases with deep respiration, although not so constantly nor to such an extent as the liver and spleen. This may be readily determined, and in some cases seen, through the abdominal wall. He has demonstrated renal mobility during breathing in the course of an operation. When an incision is made into the cushion of fat surrounding the kidney, the organ may be seen to make a respiratory excursion of an inch in extent. This peculiarity, Israel says, is often of great service in diagnosis.—*The Practitioner*, April, 1889.

Transplanting the Cornea.—The transplantation of clear corneal tissue to take the place of the opaque cicatrix which is left after ulceration has been repeatedly tried. So far the method of doing this, introduced by v. Hippel a few years ago, appears to be the only one followed by anything like permanent success. After having given the operation a more extensive trial, v. Hippel has recently (*Graefe's Archiv*, xxxiv.) published a very full account of it, and has pointed out the precautions which seem necessary at each step. Of eight cases operated on, four were considered successful. From a degree of visual acuity not amounting to more than ability to count figures at six or nine feet, the patients attained after operation $\frac{20}{CC}$. The operation itself is altogether free from danger, and may be undertaken in any case where there is not extensive attachment of the iris to the back of the leucoma, or considerable alteration in corneal curvature. A portion, generally about four millimetres in diameter, is removed from the patient's opaque cornea by means of a trephine, which is guarded by a ledge to prevent its entering too deeply, and the cutting edge of which is set in rotation by means of clockwork, in order to render it possible to obtain great precision in the depth and perpendicularity of the incision all round.

The result of Leber's experiments in connection with the flow of fluids within the eye, as well as the failure of previous attempts at transplantation, led v. Hippel to recognize that an essential condition of success consists in leaving Descemet's membrane intact. Only by doing so can the transparency of the transplanted portion be permanently maintained. In removing the portion circumscribed by the trephine with a pair of fine scissors and Graefe's knife, care must, therefore, be taken not to perforate, while at the same time as level a floor as possible is desirable. The next step consists in the removal of a portion of a rabbit's cornea. This is done with the same trephine, and must involve the whole thickness of the cornea. The difficulty in this step appears to be to keep the rabbit sufficiently quiet, although its cornea is well cocainized to permit of the excised portion having exactly the desired shape. When the portion of rabbit's cornea has been obtained it is glided into position, and care taken that it comes to lie, as far as possible, flush with the rest of the corneal surface, otherwise it is readily displaced. Iodoform is then powdered on the eye, and both eyes are bandaged and not touched for two or three days, after which a daily dressing is applied. No vascularity or intransparency of the graft occurs where it succeeds.—*Edinburgh Medical Journal*, March, 1889.

Creolin in Suppurative Otitis.—The use of creolin in ear diseases is strongly recommended by DR. PURJESZ, of Buda-Pesth. In cases of acute and chronic inflammation of the middle ear he syringes once or twice daily with a solution containing five or six drops of creolin to about nine ounces of water, in addition to which the Eustachian tube is opened up by the employment of Politzer's method, or, if necessary, by means of catheterization. Dr. Purjesz finds that creolin is an excellent antiseptic for this purpose, and in the strength employed by him quite free from any objection on the score of causing irritation. Its low price, too, makes it especially suitable in practice amongst the poor.—*Lancet*, April 6, 1889.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE . . . . . $5.00.

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, MAY 4, 1889.

SYRINGOMYELIA.

BY occasional contributions our knowledge of syringomyelia is becoming more certain and its differentiation more easy. It is a disease in which the cord contains cavities of abnormal size and distribution. As an anatomical curiosity it has been known for two centuries; as a type of disease it has only been clearly recognized during the last ten or twelve years. In Germany and France somewhat numerous contributions to its literature have been made during recent years; English and American medical writers have supplied but few. Gowers' *Treatise on Nervous Diseases*, however, contains a valuable discussion of the pathology of the affection; and Starr, in May, 1888, published in the *American Journal of the Medical Sciences* an interesting summary of its literature, pathology, and symptomatology. Debove and Déjerine (*Gaz. Hebd.*, March 1 and 8, 1889) have furnished two of the most instructive recent papers in the form of carefully detailed records of two patients who were exhibited before one of the French medical societies.

The rapidity with which, in this age of medical enterprise, the literature of a subject grows is shown by the fact that five years ago Fürstner's collection of four cases, with autopsies, was quoted as a most valuable contribution to the subject, while in 1887 Bäumler had succeeded in collecting one hundred observations—sixty-six with autopsies and clinical histories, twenty-five purely anatomical observations, and ten purely clinical cases.

Cases of syringomyelia vary greatly in symptomatology according to the size, location, and ramifications of the cavities within the spinal cord, as well as according to the congenital, stationary, or progressive character of the disease. A certain more or less regular syndrome is characteristic of the ordinary form of the affection. It is, in brief, one of atrophy, with paralysis irregularly distributed and progressing; peculiar disturbances of the sensations of pain and temperature, and marked vaso-motor and trophic disturbances, such as cyanosis, heat and flushing, eruptions, ulcerations, abscesses, changes in the excretion of sweat, and affections of the bones. The picture presented by Déjerine's patient was one of atrophic paralysis, which began at the age of twenty-five years, affecting the upper limbs and trunk; fibrillary contractions; scoliosis; no impairment of touch, but marked loss of sensibility to pain and temperature, particularly in the upper part of the trunk, the upper limbs, and the right half of the face; integrity of the special senses; abolition of the olecranian reflex; exaggeration of the knee-jerk; no marked trophic cutaneous disorders, but smoothness of the skin of the upper extremities; slight swelling of the inferior extremities of the radius and ulna; modifications in the secretions of sweat, and reactions of degeneration in certain muscles. Among the most striking disturbances present in this case, and commonly in syringomyelia, were those of sensibility; and to these, in consequence of their importance, it may be worth while to refer a little more in detail.

At the commencement of the affection, in 1848, the patient had noticed that his sensibility was defective. He could even then be touched by hot liquids without feeling it. In 1888, fifty years later, he showed the same troubles of sensibility, and thought that they had neither increased nor diminished. Tactile sensibility was absolutely normal in the trunk, the face and limbs. Sensibility to pain was much impaired at the level of the hands, forearm, arm, shoulders, and the upper part of the trunk before and behind, as far as a circular line passed under the breasts. A very sharp prick of a pin was not perceived as painful, although it seemed to the patient as if some one had touched him. Analgesia was also present over the entire right half of the head. When a needle was drawn across from right to left he felt a sensation of pain as soon as it approached

the median line. There was no retardation of the transmission of sensation. Touching him with a bottle filled with ice on the entire skin of the face, neck and throat, the upper limbs, shoulders, arms, forearms, and hands, he scarcely felt a sensation of cold. The lower limbs, the entire abdomen, and trunk above the circular line passing under the breasts were normally sensitive to cold. The patient, however, felt no difference of temperature between 30° and 50° in the same region. In the left face only, sensibility to heat was preserved, and a difference in temperature between 35° and 44° clearly perceived. Applying a bottle of water at 85° to the extremity of his fingers, he felt after some seconds a lively sensation of heat, but over the rest of the cutaneous surface mentioned water at the same temperature held on the skin for any length of time did not produce any sensation of heat.

The duration of syringomyelia is very variable; often it remains practically stationary for a long period. The case reported by Déjerine is striking, among other things, in the history of its long duration. Active symptoms of the malady first showed themselves in this patient in 1848; in 1852 he was examined by Duchenne; and Louis and Briquet, among other lights of medicine, later discussed this interesting but unfortunate patient. The examination upon which Déjerine's communication is chiefly founded was made by this physician in January, 1888. The patient is still living, fifty years after pronounced symptoms were first observed.

The diagnosis of a typical case of syringomyelia may now be regarded as not particularly difficult; but the frequently irregular character of its symptoms may cause it to be confounded with other affections, as progressive muscular atrophy, anterior poliomyelitis, particularly in the adult, amyotrophic lateral, disseminated or posterior spinal sclerosis, bulbar paralysis, hypertrophic internal pachymeningitis, and some forms of myelitis and neuritis. Cases of syringomyelia have been reported as instances of irregular forms of these various diseases. In syringomyelia, indeed, these affections do exist both in pathology and symptoms; there may be, for instance, ascending degeneration of some parts of the cord, and descending of others; the gray horns may be the seat of destructive disease; nerves may atrophy, and not rarely the nuclei of the nerves of the bulb are attacked. The point to be remembered in making a differentiation of syringomyelia is, that a certain special combination and order of development of symptoms are characteristic of an affection whose essential pathology is abnormal holes in the spinal cord, and that the affections with which it is confused are usually the results of pressure or of extension of the original disease.

A curious point in diagnosis is the fact mentioned by Déjerine, that one of the most difficult affections to distinguish clearly from syringomyelia is anæsthetic leprosy, now generally regarded as a form of multiple neuritis, the clinical tableau presented by this disease being often, in brief, Aran Duchenne atrophy, analgesia, thermo-anæsthesia, and severe trophic affections. This error of diagnosis has been made in reported cases, and Déjerine regards it as almost inevitable in the absence of the prior manifestations and etiology of leprosy. Abnormal cavities in the cord sometimes exist without giving rise to active symptoms. Gowers says that this is particularly the case in young children.

The phenomena of syringomyelia have thrown some light on disputed problems in spinal localization. The clinical history of cases shows the frequent presence of trophic disorders of the bones, skin, nails, and bladder, as well as of the muscles. This is, so far as it goes, confirmatory of the localization of all trophic centres, except those for the muscles, in the central gray matter of the cord, and is corroborative, to a certain extent, of the view that the vesicular column of Clarke in the posterior horns is a region of vegetative centres; at any rate, in the central part of the gray matter of the cord, as stated by Starr, the vaso-motor and the trophic centres for the integument, finger-nails, and joints may be located. The existence of marked depression or absolute loss of the sensations of pain and temperature, with preservation of tactile sensibility, is corroborative of the difference in localization of the paths for the conduction of tactile sensibility and of those for pain and temperature. It shows the probable identity or close anatomical relations of the latter tracts, and the distinct anatomical situation of the former. The clinical and pathological observations on syringomyelia, however, are not necessarily confirmatory of the localization of the tracts for the transmission of pain and temperature in either the central gray matter or the interior portions of the posterior horns. They are more probably rather in the ascending lateral tracts, as placed by Gowers, but as the tracts for these sensations are constantly decussating, probably in the posterior commissure, the destruction of this decussation is

sufficient explanation of the changes in sensation produced by the disease.

From the very nature of the disease, treatment amounts to little or nothing. Hot baths have been used, and the various forms of treatment recommended for sclerosis, but with no permanent beneficial result.

The Annual Meeting of the American Surgical Association will be held in Washington, D. C., on May 14th, 15th, and 16th, under the Presidency of Dr. David W. Cheever, of Boston. The following papers are announced to be read: On Sarcoma of Tonsil, by Dr. David W. Cheever, of Boston. On Hernia—a Comparison of the Various Methods Adopted for Its Radical Cure; Inviting Discussion of their Respective Merits, by Dr. C. H. Mastin, of Mobile. On the Surgical Treatment of Gangrenous Hernia, by Dr. M. H. Richardson, of Boston. On the Early Diagnosis of Morbid Growths, by Dr. J. Collins Warren, of Boston. What Forms of Peritonitis Demand Treatment by Surgical Measures? by Dr. J. Ewing Mears, of Philadelphia. On Free Division of the Capsule of the Kidney, for the Relief of Nephralgia, by Dr. L. McLane Tiffany, of Baltimore. On Digital Dilatation of the Pylorus, by Dr. J. M. Barton, of Philadelphia. Contribution to the History of Gunshot Wounds of the Intestines, by Dr. Theo A. McGraw, of Detroit. On some Modifications in the Technique of Abdominal Surgery, Limiting the Use of the Ligature *En Masse*, by Dr. Lewis A. Stimson, of New York. A Successful Case of Nephrectomy for the Removal of Cancer of the Right Kidney, by Dr. John Homans, of Boston. Drainage and Drainage Tubes in their Application to the Treatment of Wounds, by Dr. Stephen H. Weeks, of Portland. Successful Ligation of the Primitive Carotids done Almost Simultaneously, in the Removal of Epithelial Cancer from the Base of the Tongue and Fauces, by Dr. L. C. Lane, of San Francisco. On Injuries to the Axillary Vessels, by Dr. Randolph Winslow, of Baltimore. On Acute Infectious Osteomyelitis and Periostitis, by Dr. Herman Mynter, of Buffalo.

The American Public Health Association will hold its next meeting in Brooklyn, N. Y., beginning October 22d. In addition to the regular scientific business, which usually consumes the entire time of the meeting, there will be a carefully organized annex for the exhibition of sanitary appliances and life-saving apparatus. It is also proposed to give one afternoon to an inspection of the quarantine stations of New York harbor. Dr. J. H. Raymond, of the Hoagland Laboratory, Brooklyn, is Chairman of the Local Committee.

Next Tuesday the Johns Hopkins Hospital, at Baltimore, will be formally opened with appropriate ceremonies, including addresses by President Gilman and Dr. J. S. Billings. The building is the finest of its kind on this continent, and it is doubtful if it has a superior anywhere, and neither pains nor expense have been spared to make it in all respects a model hospital, as will be seen by the full description which we give of it in another column.

At their recent commencements the degree of Doctor of Medicine was conferred on graduates as follows:

University of Pennsylvania	124
Starling Med. College, Columbus, O.	28
Columbus, O., Med. College	22
Kansas City Med. College	18
University of Kansas City	15
Gross Medical College, Denver	10
Niagara University, Buffalo	9
University of Denver	8
Colorado State University	1

The Faculty of the University of Vienna has conferred upon Dr. J. S. Billings the degree of Doctor of Medicine *causa honoris*.

On the occasion of his departure for his new field of labor at Johns Hopkins Hospital, Dr. Osler's medical friends in Philadelphia will give him this evening a farewell dinner at the Hotel Bellevue.

Dr. Robert Abbe, of New York, will read a paper before the Philadelphia County Medical Society on the 8th of May, on "Intestinal Anastomosis," giving the results of his experience, not only with Senn's plates, but of his own proposed substitute of catgut rings, which we noticed editorially in our issue of April 13th. The paper will be followed by a discussion.

Dr. Harvey Lindsly, one of the oldest physicians in Washington, died in that city on Sunday afternoon, at the age of eighty-five years, from exhaustion, due to old age.

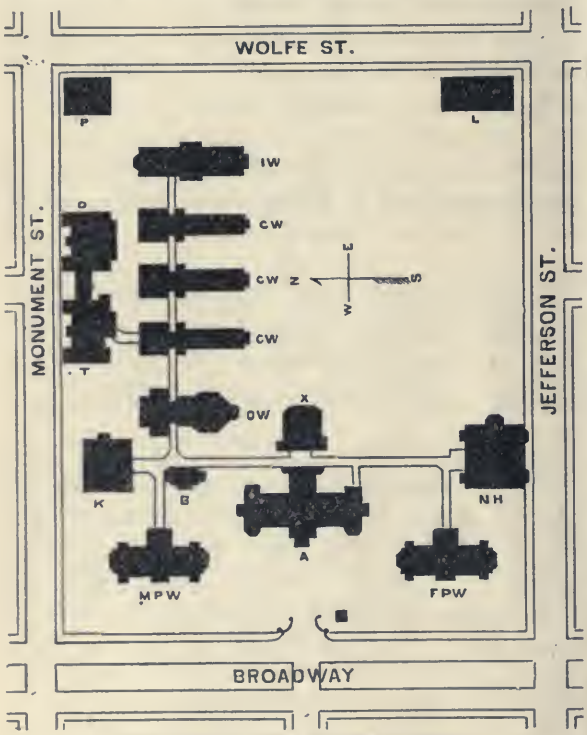
Dr. Lindsly was born in Morris County, N. J., January 11, 1804. He graduated at Princeton Col-

lege and took his degree in medicine at Washington in 1828 and then entered upon and continued in active practice in that city until 1872, when he retired. He was elected to the Presidency of the American Medical Association at its meeting in Washington in 1858. He was at one time Professor of Obstetrics in the National Medical College, and afterward Professor of the Theory and Practice of Medicine in the same school, and was for a long time President of the Board of Health of Washington City. He contributed a number of valuable papers to the *American Journal of Medical Sciences*, as well as to several magazines in general literature. He leaves a widow and four daughters.

SPECIAL ARTICLE.

THE JOHNS HOPKINS HOSPITAL OF BALTIMORE.

THE Johns Hopkins Hospital will be formally opened next Tuesday. The grounds of the Hospital include four entire blocks, containing about fourteen acres of ground, having a frontage on Broadway of 709 feet and extending back 856 feet. The buildings are seventeen in number and the roof area covers over four acres.



Block Plan of Johns Hopkins Hospital.

A.—Administration Building.	O.W.—Octagon Ward.
X.—Apothecary's Building.	C.W.—Common Ward.
M.P.W.—Male Pay-ward.	I.W.—Isolating Ward.
F.P.W.—Female Pay-ward.	T.—Amphitheatre.
N.H.—Nurses' Home.	D.—Dispensary.
K.—Kitchen.	P.—Pathological Building.
B.—Bath House.	L.—Laundry.

THE DESIGN OF THE HOSPITAL.

The Hospital has been building about thirteen years, and shares with the University the distinction of being a monument to the philanthropy and generosity of the late Johns Hopkins. The endowment is over $3,000,000, invested in substantial interest-paying securities, and only the income has been used in the construction of the buildings. With the exception of the Laundry, Autopsy Building, Chapel and Green-house, all the buildings which are of brick with trimmings of dark blue stone, are connected by covered corridors one story high. The top of this corridor forms an open terrace-walk on a level with the ward floors. The objects of the hospital, as indicated by its founder, were threefold: The proper care of the indigent sick; the education of trained nurses and incidentally of physicians; the promotion of discovery in medical science and the promulgation of the same for the general good. To these might also be added the outdoor relief feature, on which the founder laid not a little stress, and which will be among the first to which the officers of the institution will bend their energies in order to popularize the Hospital.

The medical school will not be a part of the Hospital, but of the University, though the two will work in harmony, and the students of this department will receive their practical experience within its walls.

THE GENERAL PLAN.

The first problem which engaged the attention of the trustees was the selection of a general system on which the buildings were to be erected. It is generally conceded that a village of cottages, with commodious arrangements, large, airy apartments given up to the sick, with an adequate supply of nurses, and of medical and surgical skill, would show a smaller average mortality than the more crowded ward system, just as villages are, other things being equal, more healthy than large towns. But this plan is hardly practicable for large cities, though the one-story barrack system, destructible in whole or part, which was so successfully used in the civil war, resembles it in many of its excellences. The barrack system was not found to give all the advantages that could be gained from what is known as the pavilion system employed in the construction of the present institution. The greatest objection made against placing one ward above another is based on the increased facility for the transmission of foul, contaminated air from one floor to another, and the impossibility of giving as good ventilation to the lower as to the upper floors. The plan, therefore, finally adopted in constructing this building is generally to have but one floor in a pavilion devoted to a ward.

All the pavilions have a basement nine feet high, raised above ground, laid with a granolithic flooring, containing only the heating and ventilating apparatus, and connected directly with a closed corridor ten feet wide, which communicates directly with all save two buildings, the dead-house and laundry. With the exception of the pay wards, none of the pavilions can be entered from the closed corridor except by first passing through the open air. Thus do all the floors on which the sick wards are situated communicate directly with a long, flat terraced roof on the top of the corridors, surrounded by

railings, which serves for exercise of the patients and their general communication in fair weather, and likewise affords a free circulation of air all around the wards left unobstructed on what is termed the first floor of the system.

It has been the plan of the founder to give each patient in the hospital 100 feet of floor space, in accordance with the recognized necessity of providing ample breathing space, and avoiding all the dangers common to hospitals, and to provide each bed with eight feet of wall space. It is the expressed will of the founder that not more than 400 sick persons be accommodated at any one time in the institution, and in the sixteen buildings thus far constructed the whole number of beds provided in the wards is not more than 224, not including seven in the accident wards, only to be temporarily occupied by patients undergoing treatment in that building. In the pay and isolating wards separate rooms are provided for the patients, but in the three kinds of free pavilions, the common octagon wards, beds are arranged in one room, though there are in each four separated rooms for certain cases, where special modifications of light and temperature are required.

THE COMMON WARDS.

The common wards are rectangular in form, ninety-one feet long by thirty-two feet broad, with twelve beds arranged on either side of its length, at least one window being placed between each two. For the octagonal ward system it is claimed that the beds being placed at exactly equal distances from each other and from the fireplaces and ventilators, that the difficulty of unequal heating and stagnant air spaces is avoided, but moreover that more sides of the ward are entirely free for the largest amount of sunlight and heat than by any other form. Some one part of the room is always lit up by the direct rays of the sun during some part of the day. One somewhat serious objection raised against this system is that it does not allow the attendants a fair view of every patient at the same time, as a large ventilating shaft occupies the centre of the room. But this has to be waived in consideration of its supposed greater value. It has also been urged that the sick-room does not require the watching of a penal institution. Each of the two octagonal wards will have two stories.

THE ISOLATING WARD.

The isolating ward is for the treatment of patients suffering from contagious diseases. Each person is assigned a separate apartment, whose ventilation is made through an individual shaft.

HEATING AND VENTILATION.

The problem of heating is inseparably connected with that of ventilation in hospitals, and the two were considered together in maturing the plans. The open fireplace has a conspicuous place in all the buildings where a room occupied by not more than two persons is to be heated, because of the especially agreeable effects of direct radiant heat and the cheerful appearance such fires give, and the ready means they afford of providing a rapid exit for the effete organic matter of the room. Such heating is, however, very wasteful in proportion to the heat thrown out, and will not answer for wards because of the unequal heating of objects situated at varying distances from it; they also increase labor, and are dangerous in that smoke and obnoxious gases are at any time likely to be driven from them into the wards. In the Johns Hopkins Hospital one of these open hearths is placed in every individual sick room to furnish ventilation, but to be kindled only in case the other means of heating fail, or before the large furnaces have been lit for the season. All the advantages furnished by the open grate can be obtained from the use of hot water under low pressure in coils. A very simple device, an automatic switch-damper, is applied in numerous parts of each sick room, as well as in nearly all the rooms of the hospital, to admit fresh air. All that is seen of the arrangement is a slightly altered form of a heat register, placed in the wall not far from the floor, in especially great number in the wards. The apparatus for mixing the air is placed in the basement. A certain well-defined volume of air is constantly entering through this register, an amount which the attendants cannot control, but which has been measured by experts, so as, with other arrangements in the wards, to cause a complete renewal of the air every fifteen or twenty minutes. When on damp or sultry days the air is sluggish in its upward movements a fan arrangement in the basement of each building forces it through the switch-damper.

It is proposed to place in the medical director's room in the Administration Building an electrical device called a "telemeter," by which he can see at a glance the temperature of various parts of each ward in the entire hospital, and if the heat be too great or too little he can order its modulation by decreasing or increasing the amount of air in a given switch-damper that is to pass around the coils.

For the removal of the vitiated gases there are several devices employed in the same ward, including, besides the fireplace heaters, a coil of hot-water pipes near the top of the shaft, which creates a constant upward current of some little velocity from the rooms below. In the central hall of each pavilion there is in addition an enormous shaft for ventilating each entire floor. At night when the products of combustion of the gas jets are to be removed, in the morning when all the wards are to be thoroughly flushed, and in summer that this dead residuum may be removed, ventilators at the top of the room are opened. The pay wards have individual rooms, with all the features of switch-damper ventilation below and above. In the Nurses' Home is exhibited an anemometer to measure the velocity of the current upward into the ventilating shaft, which rapid egress is necessary to replenish the pure air. The attics above the wards have also in every instance the best of ventilation.

PLUMBING.

Throughout all the buildings the pipes are exposed, so that at a moment's notice they can be examined and the source of any difficulty remedied at once. No sewer is allowed to pass directly under any building, for the waste water drains directly through special pipes down Jefferson Street into the Harford Run, and fecal matter flows through a large outlet, which is to be frequently flushed with large quantities of fresh water, into an immense well under the Nurses' Home, which is ventilated by a stack one hundred and twenty feet high.

No mouldings are allowed on the furniture or woodwork in any of the buildings lest shrinkage cause cracks

and fissures for the lodgement of disease germs. The walls are all joined in segments of circles and not in right angles, the washboard joining the floor, and the wall is similarly curved that a damp rag may allow no small fraction of an inch to go uncleansed. For a similar reason all the fittings and joints are tight, and the furniture is not carved to any extent. The floors are of well-seasoned hard yellow pine, well oiled to prevent indentation, separation at junctures, and the absorption by the wood of anything that may be spilt upon it. Rugs and druggets will not be allowed on the floors to act as sponges for imbibing and retaining bacteria of disease. In some cases, for similar reasons, granolithic floors are used where there is likely to be slopping, and soapstone walls where cracks would be likely to occur in the ordinarily plastered walls, as in the kitchen.

Extreme cleanliness is to be insisted upon in the attendants' rooms and storage-rooms. No closets with doors or drawers are furnished, that nothing soiled or improperly cleansed may be concealed.

THE OCTAGON WARDS.

The common octagon wards are placed in the southern part of each building to procure as much invigorating sunlight as possible, while at the far end (south) of each such ward is a sun-bath, where the patients may be exposed to the beneficent rays. Still the number of windows in each ward is not unnecessarily increased, for that would result in producing ill-comfort in the patients without corresponding benefit. Four separate rooms are provided in each ward, where special modifications of light and temperature desirable in the treatment of the case may be provided. In case the disease prove a dangerous one, of course the ward is emptied and the bedding and clothes thoroughly disinfected and purified, or even burned. It is hoped that one bed in each ward may always be left unoccupied, and even, if possible, one entire ward left vacated. These buildings are two stories high, with basement.

ADMINISTRATION BUILDING.

The administration building is three stories high; the upper stories are divided into rooms for resident medical officers and students. The medical director's room will contain, besides the telemeter, annunciators, and speaking-tubes to all the buildings, a pneumatic clock, in order to provide precisely the same time in all parts of the building, to regulate exactly the administering of medicines and baths. The board room is provided with the original set of furniture, books, and fittings of Johns Hopkins's library. The resident physicians and resident students' separate bed and dining-rooms and reading-rooms are in this building. A superabundance of bath-rooms is provided, in order to induce very frequent cleansing and change of linen on the part of the medical attendants. Separated from the corridor and administration building by an open-air bridge, in order to keep out the disagreeable odors from the living rooms, is the apothecaries' building, three stories high. The indoor dispensary is located here. The two upper floors are occupied with rooms for female servants.

BATH HOUSE.

In another annex are the baths of the hospital, where, if possible, the patients are induced to come. If unable to leave their beds, a complete portable bathtub is brought to the bedside. Turkish, Russian, mercury, vapor, electric, needle, plunge, and other bath-rooms are provided here for all who have them prescribed for them. Separate bath buildings are provided for males and females.

THE KITCHEN.

This building is three stories high besides the cellar and boiler vaults. The upper story contains dining-rooms for employees and sleeping-rooms for cooks. The entrance to the kitchen is by the closed corridor, and, therefore, on the floor below that to the sick wards, into which its odors cannot penetrate. All modern conveniences of steam apparatus are provided for cooking, and large hoods for carying off the vapors to the flues. All the non-commissioned officers dine here. It is provided that all the garbage and waste must be at once carried out into the open air and dumped into a shute to be carried away. All the viands for the patients are carried in felt boxes, to be kept hot by this simple device, to the wards some distance off. In each ward there is, however, a nurses' kitchen, with steam tables to prepare any simple dish that may be required for an emergency or during the night.

THE BOILER-HOUSE.

The boiler-house is beneath the surface of Monument street, and is reached from the sub-cellar of the kitchen building. It contains four hot-water and three steam boilers, the last communicating directly through a tunnel to the amphitheatre and dispensary building, which they heat. They also provide steam for the boilers of the kitchen and steaming tables throughout the buildings. The hot-water boilers heat the switch-dampers of all the buildings and tops of the ventilating shafts. Two enormous filters purify all the water that enters the institution, even that which goes to the boilers. Pumps in this boiler-house raise filtered water to tanks capable of holding 100,000 gallons in the top of the administration building. This is held as a reserve in case of an accident to the water main feeding the institution, or the breaking down of the city's reservoirs.

THE PAY WARDS.

The male pay ward is at the corner of Monument Street and Broadway. The walls are neatly painted in oil, and the furnishings are only a little better than in the common wards. An iron bedstead, with brass knobs, three chairs, a wardrobe, washstand and bureau, almost the same as in the officers' rooms, constitute the furniture. The building may be entered from the connecting corridor, but the patients' rooms cannot be reached save by passing through the central hall, where is the enormous ventilating shaft. A noticeable feature everywhere is the absence of patients' elevators, for it is believed that more comfort will be insured by raising the sick on stretchers up broad stairs with an easy rise than by subjecting them to the shock of sudden stoppages on the elevator. Fear of the rise of contaminated air through the elevator hatches also assisted in deciding on this feature. The female pay ward, at the other end of Broadway, is rapidly approaching completion, and will be ready for occupancy by the end of the year.

THE ISOLATING WARDS.

The isolating wards are for patients suffering with contagious diseases, and can only be entered by double doors from a long, high central corridor. Three rooms have the Winans perforated floor for producing an increased heat for special cases.

THE AMPHITHEATRE.

The amphitheatre building, where surgical operations will be conducted, contains seats for 200 students. Lecture-rooms, accident reception-room for patients, consulting-room, etherizing-room for preparation of patients, wards, nurses' apartments, etc., find their appropriate place in this building. There are also well-equipped rooms in which patients can recover from the effects of their operation. A movable crane, from which is suspended a strap and stirrup, is a device by which the patient can move himself when restless, from one side of the bed to another. This may be adopted in the other wards.

OUTDOOR DISPENSARY.

An adjoining building is for the outdoor dispensary. It contains a very large central waiting-room for the beneficiaries, surrounded by eleven physicians' and surgeons' rooms; there is also an apothecary's dispensing table. Baths, water-closets, etc. complete the structure.

THE NURSES' HOME.

The nurses' home fronts on Jefferson Street, and is four stories in height. It stands some distance from the end of the closed corridor, thus necessitating a passage through the open air of these attendants in going to and from the wards, and securing the home immunity from contagion. Parlors and reception-rooms, library and reading-rooms, a main hall, eight sleeping apartments for nurses, are on the first floor. Forty-four sleeping rooms for nurse students, one for each, are on the second and third floors, with all necessary conveniences. It also contains a training kitchen, a dining-room for the nurses, and a lecture-room.

THE LAUNDRY.

The laundry, a one-story building, completely isolated from the rest of the group, stands at the corner of Jefferson and Wolfe Streets, and plays an important part in the institution. Its disagreeable vapors render its complete isolation necessary. Tubs, boilers, rotary washing machines, centrifugal wringing apparatus, and other modern devices for laundrying clothes are provided. The disinfecting chamber is in the basement of this building. The roof is flat, and is to be used for sunning the clothes.

THE DEAD-HOUSE.

The autopsy building, near the corner of Monument and Wolfe Streets, now used by the pathological laboratory of the University, also stands isolated for an obvious good cause. It contains on its first floor an amphitheatre, where fifty students standing, after the plan adopted in Berlin and Strasburg, can view an autopsy. There is also an air-tight morgue-room, a waiting-room for funerals, and a pathological laboratory, all on the first floor. The upper story contains rooms for histological research and for photomicrography and a small museum. The basement will probably have a small crematorium in which to consume refuse animal matter.

GENERAL OBSERVATIONS.

Three more common wards, an octagonal ward and an isolating ward, all on the south side, a chapel and a green-house remain to be constructed. There will, moreover, be extensive gardens.

For the above description we are largely indebted to the columns of the *Baltimore Sun*.

REVIEWS.

THE PATHOLOGY, CLINICAL HISTORY, AND DIAGNOSIS OF AFFECTIONS OF THE MEDIASTINUM OTHER THAN THOSE OF THE HEART AND AORTA: Being an essay to which was awarded the Fothergillian medal of the Medical Society of London, March, 1888. By HOBART AMORY HARE, B.Sc., M.D. (Univ. of Pa.), Demonstrator of Therapeutics and Instructor in Physical Diagnosis in the University of Pennsylvania, etc. 8vo., pp. 130. Philadelphia: P. Blakiston, Son & Co., 1889.

DR. HARE in writing this book on mediastinal disease has well earned the Fothergillian medal, for he has rendered good service to the medical profession not only in calling attention to a subject of vast importance, but also for resuscitating it from an oblivion into which it was driven by undeserved neglect. He gives here the tabulated record of five hundred and twenty cases of mediastinal disease other than those of the heart and aorta, distributed as follows: Cancer, 134; sarcoma, 98; abscess, 115; non-suppurative inflammation, 16; lymphoma, 21; fibroma, 7; hæmatoma, 6; dermoid cysts, 11; hydatid cysts, 8; various other diseases, 104; and nearly every one of these classes is discussed in relation to its pathology, etiology, diagnosis, and treatment.

The study of mediastinal disease, to say the least, is of as much importance as that of any other affection within the thoracic cavity, partly because it is of more difficult recognition, and partly because it bears a most essential relation to diseases of neighboring organs, notably to those of the respiratory passages and the heart. There can be no doubt that many diseases of the larynx, lungs, and heart, which are commonly attributed to local causes in these organs, will find a solution of their origin in the pressure of a mediastinal lymphoma, fibroma, etc., on the recurrent laryngeal or on the pneumogastric nerves, the pulmonary, or on the cardiac plexuses. This is especially true of such affections which invade the posterior mediastinal space.

We congratulate the author on the happy selection of his subject, and on the faithful manner in which he worked it out, as well as on the intelligent appreciation which it is receiving from the profession.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON NEUROLOGY.

LANDON CARTER GRAY, M.D., CHAIRMAN.

Stated Meeting, April 12, 1889.

NERVOUS SYMPTOMS ARISING FROM OVARIAN DISEASE, AND THEIR TREATMENT.

DR. CHARLES L. DANA, in opening a discussion on this subject, said that in these cases the gynecologist had

the advantage over the neurologist in the fact that he not only observed the symptoms but also saw the ovaries themselves. The term ovarian irritation he took to imply an irritating organ, and not an irritated organ, as in cardiac irritation, for instance, when the heart was irritated by reflex nervous influences. The question at issue must be confined to ovarian irritation, if there was such a thing. The designation was hardly correct, however, since the uterus and the tubes were appendages of the ovaries and might share in the trouble.

Then, a point arises as to the anatomical and physiological basis of ovarian irritation. In many cases there might not be any anatomical change in the organ, but merely a physiological or functional one. By far the most frequent change present, however, was chronic hyperæmia or chronic ovaritis. This was so important a condition that we might, for the most part, dismiss from consideration the parenchymatous changes resulting in the formation of cysts, etc. It was a well-recognized fact that such changes were not accompanied, as a rule, by the reflex nervous symptoms that often characterized the condition of chronic hyperæmia or chronic ovaritis.

To the latter it had been customary to refer a great variety of nervous affections, such as vaso-motor disorders, cardiac disorders, hysteria, epilepsy, mania, melancholia, chorea, neuralgic states, spinal irritation, sciatica, migraine, and irritability of the bladder and rectum. The question, therefore, arises, How far are such conditions really attributable to the ovaries? In his own opinion, he said, if the ovaries were anatomically healthy they could not produce these reflex troubles, and chronic ovarian hyperæmia and chronic ovaritis could not produce any of the severe constitutional neuroses alone. He also believed that the latter had much less effect in the causation of such troubles than was generally supposed, and that the removal of the ovaries did not, as a rule, remove grave neuroses, such as chorea, epilepsy, melancholia, and intractable neuralgias. About one-half of such troubles usually occurred in women whose ovaries were perfectly healthy; while in those whose ovaries were really seriously diseased none of these neurotic symptoms manifested themselves.

Battey, of Georgia, had discovered a peculiar form of epilepsy which he designated as ovarian epilepsy, and had reported ten cases of it in which he removed the ovaries, with the result of a cure in eighty per cent. of the cases. It was extremely probable, however, that the greater number of these cases were simply instances of convulsive hysteria, which was likely to get well under almost any course of treatment. It was certainly a fact that no such disease as ovarian epilepsy was recognized by neurologists, and neither Gowers nor any other author who had written systematic treatises on epilepsy made any mention of it. Of so-called ovarian mania, Battey had reported four cases, with one cure, and Goodell five cases, with four cures, from removal of the ovaries. They were, no doubt, instances of hysterical insania, and according to Clouston, the proportion of cures in this affection under any treatment amounted to sixty per cent.

As the greater number of such cases were hysterical in character, the percentage of cures by operative procedure did not present a very brilliant result, and it was, moreover, a fact that in a very large number of hysterical women there was no appreciable disease of the ovaries or uterus whatever. In hysteria the mind of the patient was apt to become specially directed to certain points in the system, and it was perfectly natural that many patients should come to regard the pelvic organs as the source of their troubles; so that the removal of the ovaries would at least have a very strong moral effect. On the whole, therefore, it was his opinion that the ovaries by themselves occupy a very subordinate place in the production of neuroses. Although an inflamed ovary might cause considerable neurotic trouble, the same might be true of any other process of disease in the system, and hysteria was essentially a brain affection.

DR. W. GILL WYLIE said that he was substantially in accord with the main points advanced by Dr. Dana. He was inclined to think that the influence of the ovaries in producing reflex nervous symptoms has been overrated. Without doubt an inflamed or diseased ovary will cause marked reflex symptoms, but much depends upon the condition and inherited tendencies of the whole nervous system of the individual. What he meant, he said, was this: that the same disease of the ovary in different women will cause very different symptoms. In a delicate, imperfectly developed woman a diseased ovary may make a confirmed invalid and cause numerous reflex symptoms, while a well-developed woman, with a normal, well-balanced nervous system, may carry about a diseased ovary without ever being confined to her room, and not have any definite reflex symptoms.

The imperfectly developed woman is almost certain to have an imperfectly developed uterus and ovaries, and is, therefore, much more liable to have uterine and ovarian disease than the average woman, and it must not be forgotten that imperfectly developed women are also prone to have a diseased or abnormal nervous system. He was convinced that it is often very difficult to separate the symptoms actually caused by disease of the ovaries from those due to an abnormal or imperfectly developed nervous organism. He has also found that chronic uterine or ovarian disease is nearly always complicated with a disease or at least an abnormal condition of the rectum or colon, and he had made some very brilliant cures of cases of supposed uterine or ovarian disease by dilating the anus and removing the reflex disturbances caused by an anal pressure. In other cases he has found the colon dilated and sacculated (being loaded with round, hard scybalæ), and this condition has been at the bottom of a case of melancholia or hypochondriasis supposed to be due to disease of the left ovary.

An inflamed ovary will cause reflex symptoms, especially for some days preceding menstruation, on account of the increased vascular tension existing at that time. An ovary imprisoned by a firm peritoneal exudation will cause unusual reflex symptoms and local pain, due to the resistance offered to the maturing ovum swelling under the peritoneal adhesions, or to the occluded Fallopian tube and abnormal ovulation resulting in cystic degeneration and the swelling cysts stretching the peritoneal adhesions. He has seen several cases where the reflex symptoms amounted almost to insanity, caused, as was shown when the abdomen was opened, by a thickening and hardening of the ovarian tissue, resulting in the production of a very great increase of the fibroid tissue, and, in some cases, of small nodules or fibroid

tumors on or in the ovary. In this class of cases the patients suffer intense local pain, and just before menstruation become very irritable and excitable to an extreme degree.

As to treatment, in all cases where the reflex symptoms or the nervous symptoms are marked, he invariably gets the advice of a neurologist before resorting to active treatment, so as to avoid the mistake of exciting and bringing to a climax some commencing or undeveloped disease of the nervous system. Then, before attempting to reach a positive diagnosis he makes it a rule to keep the patient for some weeks under his own observation, unless the symptoms demand immediate surgical interference. Also, before deciding whether an ovary is enlarged or decreased, he thinks it wise to insist upon an examination of the patient under ether. If one can plainly make out disease of the ovaries, indicated by fixation or enlargement—that is, permanent enlargement, the organ being as large as a small hen's egg—and if the symptoms are not relieved or rendered latent by improving the general health of the patient, or by the use of means to improve the local circulation, such as counter-irritants, etc., then laparotomy should be considered, if the subjective symptoms warrant it.

But unless actual physical disease can be plainly made out by local examination under ether, he would not advise laparotomy until every other means, in the hands of several different physicians, have been faithfully tried. He said he was sure that in many cases where the ovaries have been removed, if the influence of imperfect development had been recognized, and a simple stimulating local treatment, combined with careful attention to improving the general condition, had been properly carried out and persisted in, the patients would have saved their ovaries and regained their health as completely, if not more completely, as by castration. In these cases he said he was accustomed to apply cotton pledgets soaked in a solution of boro-glyceride and glycerine twice a week, to dilate the uterine canal once a week between the menstrual periods, and make a stimulating intra-uterine application. In some cases he applied electricity, and in others put in a drainage plug for a week every three or four months, etc.

When there was distinct nervous disease he did not think much could be accomplished by the removal of the ovaries. Personally he had performed the operation in but five cases, and only one of the patients was cured, while three were not at all benefited.

DR. B. SACHS said it would seem that both neurologists and gynecologists were of one opinion in regard to this matter. At the present day he did not suppose that any of those present would think of removing the ovaries in cases of chronic neurosis, such as epilepsy or chorea. He referred to cases of epilepsy in which this was done, and said that even in a case of hystero-epilepsy which had come under his observation the ovaries were found to be perfectly normal after removal. The question that all would like to have determined was: What effect has disease of the ovaries on chronic hysteria, and is the removal of these organs justifiable in this condition or not? As far as he could judge, if there was considerable enlargement of the organs, or they were in a state of chronic inflammation, this would seem to afford ground for their removal. But in the majority of cases of hysteria such conditions did not exist, and the question, therefore, arose: Are we justified in removing a normal ovary? Where there was ovarian hyperæsthesia there was likely to be a general hyperæsthetic condition of the system, and by the extirpation of the ovaries we simply removed one focus of trouble, without in any way affecting the others that remained.

He should like to see statistics furnished which would show in cases of true hysteria how many were cured by the removal of the ovaries when diseased, and how many by the removal of the ovaries when normal. His own experience went to show that after the removal of the ovaries the symptoms always return after a longer or shorter period of time.

DR. M. P. JACOBI spoke of the necessity of distinguishing between those cases which have their origin in the ovarian region and those which arose in simply an hallucination of the brain, but referred by the patient to the pelvic organs. In the constitutional hysteria in which the most pronounced symptoms were developed, the patients were, as a rule, entirely free from ovarian or uterine disease, and in such cases any effect that operative interference could have would be due simply to the mental impression made upon the patient. It was her opinion that ovaritis never occurs as a primary disease, but invariably originates in a fundal endometritis. On this account she thought it exceedingly important to distinguish between the symptoms due to ovarian and those due to uterine disease, and to bear in mind the fact that disease of the uterus and the ovaries often existed together.

She believed that the symptoms of chronic nausea and chronic tympanites were especially characteristic of lesions of the utero-ovarian nerve. All the filaments of the ovarian nerves had been traced to terminations in the bloodvessels, and hence, primarily, there would be vaso-motor disturbances. After some remarks on the influence of the sympathetic system, she said that the English authorities especially had long recognized ovarian dyspepsia, which was atonic in character, as among the remote effects, and in the treatment of this condition Tait had applied strong counter-irritation to the region of the ovary with success. In conclusion, she related the case of a patient suffering from very severe ovarian dyspepsia who was completely relieved by the application of a strong current of electricity, one electrode being placed over the lumbar vertebræ and the other over the ovarian region in the hypogastrium.

DR. W. R. BIRDSALL said that it seemed to him that the conclusion expressed by Dr. Wylie in regard to operative interference was correct, and he fully agreed with him that the removal of the ovaries was not called for unless active disease of these organs could be demonstrated, except in special cases where all other means of treatment had been faithfully and persistently tried. But even in such cases the results thus far accomplished had not been such as to encourage the resort to operation, and he believed that the more evidence accumulated the less frequently would the ovaries be removed. There was a class of neuroses in which, if one chain of evidence of symptoms was relieved by a special course of treatment, trouble would sooner or later break out in another part of the system. Thus, he knew of patients who had successively had their nasal septa straightened, their ocular muscles cut, their uteri cured of malpositions, and their bladders and rectums relieved of irritation. All these methods of treatment had improved the

condition of the patient for the time being, but scarcely had one set of symptoms been controlled by the measures employed when a new set would become developed. At the same time, he believed that whenever there was distinct local disease the removal or relief of this source of irritation was of decided benefit; but he thought that the mistake was too often made of considering these local lesions as the primary cause of trouble, which was really to be referred to the general neurotic condition of the patient.

He agreed with Dr. Jacobi that the uterine disease was frequently associated with that of the ovaries, and in this connection he mentioned the case of a patient, a married woman, who at times was subject to a sinking sensation amounting almost to unconsciousness, which she referred to the ovarian region, the stomach, and down the thigh. On making a physical examination he found anteversion of the uterus and prolapse of the ovaries. As soon as the displaced ovary was touched, she complained of the sinking sensation mentioned, and he felt convinced that a large part of the patient's nervous trouble was due to the abnormal local condition present. He, therefore, called in a gynecologist, who, after replacing the uterus put in a pessary, which also had the effect of keeping the ovary up, and after this she had no further trouble. On the other hand, he had seen many instances in which attacks of this kind were not relieved by local treatment.

In cases in which the ovaries are bound down by adhesions the pain is often extreme and the nervous symptoms quite marked. There is another class of cases, of which he had not seen more than two or three instances, where the pain was as persistent after the removal of the ovaries as before; and he believed it to be a fact that the removal of a painful organ does not necessarily cure a neuralgic pain long established. This was shown by the not infrequent failure of resection of nerves to afford relief in chronic neuralgias; and hence, if neuritis was the cause of the trouble, the removal of the ovary might not effect a cure. There might indeed already be present disease of cerebral origin. In conclusion, he said that he believed there were two extremes to this question. No doubt many ovaries had been removed which had better been left; but at the same time he thought that in the future cases would sometimes occur in which the removal of the ovaries would be attended with benefit.

DR. H. T. HANKS said that as a practical gynecologist he would take the standpoint of Dr. Wylie. As he had stated, there were some conditions of the ovary which could be relieved by patient and long-continued local treatment; and electricity was often very beneficial in this connection. When the ovaries were bound down by adhesions ovulation took place with the greatest difficulty, and much suffering resulted to the patient; and in cases where removal of the organs was not deemed advisable great relief could often be afforded by the application of electricity just previous to the menstrual period. If we were able to determine just what condition was present, great relief could sometimes be secured by very simple means. Having referred to one or two illustrative cases, he said that in view of the very large number of laparotomies which had now been performed, he thought gynecologists ought to be able to come to a positive conclusion in almost every case presented to them whether the ovaries ought to be removed or not. When a decidedly diseased ovary which was hypertrophied or prolapsed was met with, and this was attended by the symptoms usually characteristic of such a condition, he thought that the operation should be performed.

DR. H. J. BOLDT desired to take the same standpoint as most of the other speakers, and he related the case of a bed-ridden patient whose ovaries he removed in the hope that she would improve. She did improve for a time after the operation; but later all the symptoms came back as bad as before. In hystero-epilepsy he thought proper cases for operation would be those in which, in spite of all other treatment, the attacks continued to increase in frequency. In two cases of his own of this kind, however, the removal of the ovaries was not attended with success. There was improvement for a time, and then the attacks returned as bad as ever. His experience had, therefore, led him to the opinion that in any case where the ovaries appear to be normal, no matter how severe the nervous symptoms may be, the removal of the ovaries will not afford relief. On the other hand, in cases where the ovaries were bound down by firm adhesions, such as those referred to by Dr. Birdsall, he would expect great benefit to be derived from the operation. In some cases of nervous trouble the symptoms were decidedly worse after operation than they had been before, and he thought that the ovaries should never be removed until all other means of treatment had been exhausted. In addition to electricity, massage often proved of very great benefit, and he thought this means was not resorted to as frequently as it ought to be.

DR. M. D. FIELD said that his experience as an examiner in lunacy led him to the belief that many women who have had their ovaries removed are in our insane asylums to-day. A considerable number of the cases which he had seen had come directly from Bellevue Hospital, where the operation had been performed. He had no doubt, however, that many of them had a predisposition to insanity before the removal of their ovaries, and that the shock of the operation or the effect of etherization brought on the mental trouble.

DR. GRAY said it seemed to him that the whole question of reflex nervous symptoms was intimately connected with the growth of the various specialties in the last few years, and that unless specialists had some competent knowledge of the nervous system and its pathology they were apt to get into all sorts of vagaries. If one desired to relieve an epilepsy, for instance, it was necessary that he should understand what epilepsy does when left to itself. Almost any kind of treatment would often do good for a time in this affection; and the same was true of hystero-epilepsy and hysteria. The trouble was that the specialists did not study the intrinsic history of the disease. Reflex disturbances coming from the viscera were almost always suspicious. The involuntary nervous system constituted an element of great importance, as Dr. Jacobi had pointed out, and it was necessary to understand clearly the difference between the voluntary and the involuntary nervous systems. While, as a rule, he was very sceptical about the cure of epilepsy by gynecological operations, he had seen two cases in which the relief of a vaginitis which was present relieved the epilepsy.

DR. WYLIE said that where no ovarian disease could

be detected he would operate only in extreme cases in which the patients were bed-ridden and all other means had failed to give relief. As a rule, he would remove the ovaries only when these organs were clearly demonstrated to be seriously diseased. As to the cases referred to by Dr. Field, the patients were no doubt exceedingly nervous to begin with. In one case which Dr. Dana had seen in consultation, the patient was already insane before he operated. He removed the tubes and ovaries on account of the presence of a well marked pyosalpinx, and the operation was followed by considerable amelioration in the condition of the patient. If insanity were so common a result of removal of the ovaries as Dr. Field would seem to intimate, he thought the cases should all be published with complete histories.

DR. DANA said that the opinion which he had entertained up to the present occasion, as derived from recent works on gynecology and current medical literature, was that gynecologists were accustomed to resort very frequently to removal of the ovaries for the relief of these nervous troubles; and he was very glad to find that the sentiments expressed in the discussion to-night were adverse to frequent operative interference, and, therefore, considerably in advance of the views held of late by many in the profession, as expressed in text-books and medical journals.

SECTION ON THEORY AND PRACTICE OF MEDICINE.

R. C. M. PAGE, M.D., IN THE CHAIR.

Stated Meeting, April 16, 1889.

DR. F. W. JACKSON read a paper on

THE SIGNIFICANCE OF THE CREPITANT RALE.

Not long since, he said, a fellow-practitioner had remarked to him in regard to the actual significance of the crepitant râle that it only means pneumonia. This was the position practically taken by the late Dr. Austin Flint, who in his *Manual of Auscultation and Percussion*, said: "The crepitant râle is the diagnostic sign of pneumonia. It very rarely occurs in any other pathological condition. Of all respiratory signs this is the most entitled to be called pathognomonic." Dr. Jackson contended that this sign alone is not diagnostic of pneumonia, and that it is simply a sign of pleuritic changes or inflammation, and perhaps of other conditions of the lung as well.

Nearly all writers practically followed the teachings of Laennec or Walshe. He quoted the description of Laennec, in which he speaks of the crepitant râle as occurring in the pulmonary tissue and carrying with it a well-marked sensation of moisture. On the other hand, Walshe had said: "Dryness is one of the best marked acoustic properties of true crepitation; the sensation is not that of bubbles bursting, but rather that of a delicate tissue undergoing minutest ruptures with a crackling noise at many points simultaneously."

As regards the mechanism of the crepitant râle the three leading theories were:

(1) That of Laennec, according to which it is due to the bursting of fine bubbles of air through a viscid fluid in the air vesicles or alveolar passages of the lung.

(2) That favored by Walshe, that the sound is due to forcible distention of the air vesicles, whose walls are rendered stiff by a glutinous exudation.

(3) That advocated by Dr. James R. Leaming, that the sound is produced by the rubbing together of the two surfaces of an inflamed pleura which is coated with fibrin.

All the older writers and most of the modern European ones favored the intra-pulmonary origin of the râle, while many of the more recent writers and teachers, in New York, at least, ascribed it to pleuritic exudation. Nearly all modern writers agreed, however, that it is not pathognomonic of pneumonia.

The exact study of the phenomena of râles demands that the sound shall have been heard at the shortest possible period before death, its position on the chest wall and acoustic characters carefully noted, and then that the lungs and pleura be subjected to a critical post-mortem examination with reference to these data. In the cases thus far studied in this way by him he has found that where a fine râle was heard on inspiration some pleural changes were commonly noted at or near the site of the râle, but not always of such a character as to be convincing. In an extended clinical experience, a point of view from which he could speak with more confidence, he said that he had noted some differences from the rules laid down in the text-books. Thus, the crepitant râle was not always persistent, (sometimes disappearing and reappearing alternately in a short space of time), and the extremely fine, extremely dry sound occurring in a great number of crackles was found to be a rare form of crepitant râle, whether associated with pneumonia or any other pathological condition. Of the brilliant, explosive, abundantly crackling type of râle, that which is slightly moist and a trifle more coarse in quality seemed to him to be far more common, and he has frequently observed it in acute lobar pneumonia, acute dry pleurisy, and phthisis, and less frequently in broncho-pneumonia.

He has been struck with the number of patients who apply for treatment whose chief or only complaint has been of pain in the chest, and in whom careful examination revealed as physical signs a little dulness and a variable number of fine râles, either crepitant or subcrepitant in character. These sounds are superficial, localized in a small area, and increased by cough or deep inspiration, and so common has he found this condition, which he regards as due either to old or recent fibrin on the pleura, or to pleuritic adhesions, that he rarely makes the diagnosis of intercostal neuralgia or muscular rheumatism. Râles at the apices of the lung, if old pleurisy be excluded, he commonly finds to indicate phthisis, and refers to a localized pleurisy. While it might be urged that these sounds were not crepitant râles, they corresponded in everything but the element of a "shower of crackles" to the definition, and they certainly constituted a very fine râle heard on inspiration. Dr. Jackson said he had sometimes heard the crepitant râle present during the second stage of pneumonia, though the number of crackles was much less than in the first stage, and in some instances it required strained attention to hear it. He has always regarded the râle of œdema of the lung as a subcrepitant râle of a peculiarly liquid character. The conclusions which he drew from his study of this subject are:

1. The crepitant râle is not pathognominic of pneumonia.

2. It is heard also in dry pleurisy, in broncho-pneumonia, and in phthisis.

3. There is a strong probability that it is almost always due to pleuritic inflammation.

4. The question as to whether it is heard also in pulmonary œdema and pulmonary apoplexy is unsettled.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, April 2, 1889.

THE PRESIDENT, GEORGE W. JACOBY, M.D., IN THE CHAIR.

The first order of business was the

ELECTION OF OFFICERS FOR THE ENSUING YEAR.

The following were chosen:

President.—George W. Jacoby, M.D.

Vice-Presidents.—W. R. Birdsall, M.D., and C. L. Dana, M.D.

Recording Secretary.—Frederick Peterson, M.D.

Corresponding Secretary.—E. D. Fisher, M.D.

Treasurer.—G. M. Hammond, M.D.

Councillors.—Drs. E. C. Seguin, M. D. Field, L. C. Gray, B. Sachs, and M. A. Starr.

DR. C. L. DANA then presented for Dr. J. W. S. Gouley a specimen of the spine and spinal cord in a case of

FRACTURE OF THE BODY OF THE TWELFTH DORSAL VERTEBRA, WITH COMPRESSION OF THE CORD.

The case was of especial interest in connection with the subject of spinal surgery, and of operative interference in cases of fracture and paraplegia. The man, aged twenty, fell, on April 19, 1887, through a floor, ten feet, striking on the abdomen and then turning on the back. Complete motor and sensory paraplegia, with involvement of the sphincters, at once set in. When examined next day by Dr. Gouley, at Bellevue Hospital, the lower limbs were motionless, and there was total anæsthesia up to Poupart's ligament on the left side, and half way up the thigh on the right. The feces came away involuntarily, and the urine had to be drawn. There was no record of fever or pain, except a little of the latter in the back. The patient's condition remained without much change, except that the legs became atrophied and the reflexes lost, for two years, until his death in February, 1889. The autopsy showed fracture of the body of the twelfth dorsal vertebra, and pushing forward of the fragment, reducing the size of the canal to three millimetres, and cutting the cord almost in two. The cord was disorganized at its lower extremity, and secondary degenerations were present, which would be studied later.

DR. PHILIP C. KNAPP, of Boston, then reported

A CASE OF TUMOR OF THE BRAIN; REMOVAL; DEATH.

The patient was a man, aged thirty-two, a florist, with a good personal and family history. In the summer of 1886 he had some nausea and vomiting, and the next winter his hand began to feel stiff. In March, 1887, he had a convulsion, and about the same time he lost power in the left hand. Since that time he had had repeated convulsions, in many of which the left hand was first affected, and a left hemiplegia with contracture. Vision had steadily failed, the mental powers had declined, he had headache, vertigo, nausea, and vomiting. Physical examination showed tactile and thermal anæsthesia on the left side, most marked in the left forearm; loss of muscular sense on that side; double optic neuritis; paralysis with contracture; diminished cutaneous and exaggerated tendon reflexes on the paralyzed side. He was admitted to Boston City Hospital December 17, 1888, and on the 28th a tumor was removed by Dr. E. H. Bradford. The tumor was a tubercle, weighing thirty-five grammes, and bacilli were found in it under the microscope. It was subcortical, and situated in the ascending frontal and parietal convolutions of the right hemisphere, about opposite the second frontal convolution, extending downward and backward into the inferior parietal lobule. The patient died of shock in three-quarters of an hour. There was no autopsy. The localizing symptoms were the convulsions, paralysis, and anæsthesia. The proportion of tumors accessible to the surgeon was regarded, on comparison of statistics, as about five to seven per cent. Fifteen cases had thus far been reported in which the tumor had been removed, and eight recovered from the operation. Four cases of operation for cerebral cysts were cited, and four cases where the tumor was not found at the operation, but was discovered later at the autopsy. Some measurements on skulls and heads were given, showing the inaccuracy of Broca's method of cranio-cerebral topography.

DR. DANA said that neurologists should feel congratulated in that their part in Dr. Knapp's case turned out so correctly and satisfactorily. He thought this case tended to confirm the view that the motor areas represent also to a considerable extent cutaneous sensation. Dr. Knapp's statistics showed that operations have been quite successful, yet he had made them too flattering. The mortality is somewhat larger. He thought, as regards cerebral surgery, that surgeons have not yet reached the degree of perfection in technique that is necessary. The length of time of the operation should be reduced, and hemorrhage more carefully guarded against. As to cranio-cerebral topography, no more accurate rule was needed than that of Horsley for finding the Rolandic fissure; it is more difficult to discover the fissure of Sylvius, and the rules for reaching its position on the skull are inexact.

DR. FRANK H. INGRAM presented a case of

HEMICHOREA FOLLOWING CRANIAL INJURY.

An adult man sustained, seventeen years ago, a depressed fracture of the skull in the left parieto-frontal region. After two years choreiform movements developed in the right arm, gradually extending to the right leg and right side of the neck. Dr. Ingram ascribed the hemichorea to some organic lesion over the motor areas of the right hemisphere, indirectly traceable to the injury to the skull.

DR. BIRDSALL said that this case resembled one of his where a young man, aged fifteen, received a charge of buckshot in the head, near the angle of the jaw. Twenty or thirty buckshot were taken from the skin, and a few entered the brain. He developed in one-half hour chorciform movements on one side, but there was also slight paresis of the same side. He had regarded this case as a post-hemiplegic chorea.

DR. STARR remarked that the movements in this man,

as far as the right side was concerned, were almost precisely like those of case of paramyoclonus multiplex, which he had reported some time ago. There were the same violence and irregularity.

DR. SACHS thought there could be no injury to motor areas in Dr. Ingram's case, because, instead of any paresis there was actually very great strength on the choreic side. He believed it to be a functional neurosis and not organic.

DR. STARR called the attention of the last speaker to the fact that we may have hemiathetosis without paresis, although an organic lesion may be discovered post-mortem. He referred to two cases, one of his own and one at Charity Hospital, in both of which the strength was perfect on the affected side.

DR. FIELD stated that the case mentioned by Dr. Starr, at Charity Hospital, had recently cured herself by prayer, and was a case of hysteria. This was the second time prayer had caused cessation of the athetoid movements in her case.

DR. W. M. LESZYNSKY then presented a case of

HEMORRHAGE INTO THE CERVICAL REGION OF THE SPINAL CORD.

J. B., aged nineteen years, clerk, sixteen months ago wrestled violently with a room-mate, was exhausted, lay down and slept one-half hour. He awoke with a dull pain between the shoulders and wrist-drop on both sides. In twenty minutes all four extremities became paralyzed. During the first week there was occasional loss of control of sphincters. In three months was improved so that he could walk without assistance, the left hand and arm, however, being decidedly paretic. At present there is partial paralysis of the left cervical sympathetic, producing contracted pupil and increase in surface temperature; paralysis and atrophy of muscles of left hand with degenerative reaction; thenar group of right hand also atrophied; both hands cyanotic; no sensory disturbance; tendon jerks in arm increased; also a few changes in lower extremities. He thought the lesion to be intra-medullary hemorrhage into the lower cervical segment of the spinal cord, followed by transverse myelitis.

DR. STARR thought that the diagnosis made by Dr. Leszynsky was defensible. The loss of pain and temperature sense was a very interesting point in the case. The literature of syringomyelia shows that lesion of the gray matter of the cord cuts off the pain and temperature tracts below the lesion.

CORRESPONDENCE.

PLATE MATERIAL FOR INTESTINAL SURGERY.

To the Editor of THE MEDICAL NEWS,

SIR: I noticed your editorial in this week's issue and have also read the report of Dr. Abbe's case in the *New York Medical Journal.*

All the plates used by Dr. Senn were made in this institution, and we, from the first, felt the necessity of a "plate material" which could be extemporarized or prepared hurriedly by the surgeon when called to the country, say to a strangulated hernia where gangrene had set in, or a case of gunshot wound, or any of the thousand and one emergencies which may occur at any time. If Dr. Abbe felt the necessity of a substitute for the bone plates, how much more so must we have felt this need in Dr. Senn's series of experiments. We have tried almost every imaginable substance, but finally cried "eureka" when we used plates made of cartilage from the scapula of a young steer. This substance can be carried in segments and easily and quickly cut down to any size. We have a specimen of intestine taken from a large dog, where the intestine had been severed in four places and again united by four sets of cartilage plates (at one operation) with perfect union at each point of apposition. It would seem to me that the catgut rings as made by Dr. Abbe are not so good as plates, because there is not so large a surface of the intestine held in apposition. Will not some one undertake a series of experiments to find the best material for plates which can be obtained or prepared on short notice? Most respectfully yours,

M. E. CONNELL, M.D.

WAUWATOOSA, WIS., April 15, 1889.

THE MEDICAL EXAMINERS' BILL AND A FOUR-YEARS' COURSE.

To the Editor of THE MEDICAL NEWS,

SIR: The following is forwarded to you for publication. Yours, W. W. KEEN.

APRIL 4, 1889.

TO WILLIAM PEPPER, M.D.,
Chairman Com. Med. Examiners' Bill.

DEAR DOCTOR: The Faculty of the Woman's Medical College of Pennsylvania, being deeply interested in the advancement of medical education, have watched closely the attempt to secure the passage of a law establishing a State Board of Examiners, and have noted the amendment proposed by your Committee.

This College, as long ago as 1869 (see announcement for that year), introduced an elective three years' graded course of instruction, which was made *obligatory* in 1881. A *four years' course* has also for some years been provided by the College, and, as a matter of fact, elected by about *thirty per cent.* of the students; and the Faculty have it in contemplation to recommend, at an early date, to the Board of Corporators of this College, that a four years' course be made essential for graduation.

In view of these facts, the Faculty are fully prepared to advocate the proposed amendment of the bill making a four years' course obligatory.

(Signed) CLARA MARSHALL, M.D.,
Dean of the Faculty.

NEWS ITEMS.

The New York Hospital Library.—This library has recently received a legacy which materially augments the value of its already remarkable collection. The late Professor T. T. Sabine left about five hundred bound volumes and two hundred and fifty pamphlets, monographs, theses, etc.. to the institution. On the 4th instant word was received at the library that the late Professor John Call Dalton also had bequeathed about a hundred and fifty volumes to the library, consisting mostly of works on physiology. They thus supplement admirably the collection of volumes given by Professor Sabine.

The library, as a whole, has become so valuable that the steps recently taken by the governors of the hospital to provide for its establishment in a new fire-proof build-

ing to be constructed on the adjacent lot on the east side of the one it now occupies on West Sixteenth Street will be watched with solicitude by all interested in the safety of this valuable collection.—*New York Medical Journal*, April 13, 1889.

The Results of State Medical Examinations in Minnesota.—Since its establishment the Minnesota Board of Medical Examiners have had eighty-six applications for examination for a license to practise medicine. Of these, six were refused admission because they had not taken three full courses of lectures of six months each. Of the eighty entering the examination, fifty-one were found able to pass the same. Twenty-nine were rejected as not possessing the knowledge of medicine required by the Board. Of those passing, forty-nine are regular, and two are homœopathic. Of those rejected, eighteen were regulars, eight homœopaths, and three eclectics. Students from two-term medical colleges cannot even get a chance to be examined in Minnesota.—*American Lancet*, April, 1889.

Curious Injury to the Brain.—An inquest was held last week by the Coroner for Central Middlesex on the body of a man who died in consequence of an injury inflicted by a poke with an umbrella. The ferrule was thrust into the left eye of the deceased, who promptly lost consciousness, and was conveyed to the police station under the impression that he was suffering from the effects of drink. Early the next morning he was liberated, and went home, but severe symptoms of cerebral injury set in, and he died in the course of a few hours. At the post-mortem examination it was found that the point of the umbrella had broken through the thin plate of bone forming the roof of the orbit, and had penetrated the brain substance. A number of cases are now on record in which this particular injury has caused death, and it is curious to note that in most of them the advent of serious symptoms was delayed for some hours, even when the laceration of brain substance has been very extensive.

In a case which was admitted some years since into the Westminster Hospital, a stick had penetrated four inches without leaving any mark of external injury beyond some slight conjunctival ecchymosis, and in this case, too, the nature of the injury was only revealed on the post-mortem table. It would hardly be fair to expect the police to diagnose an injury which, in the absence of a clear history of what had happened, would be very likely to escape recognition by skilled observers.—*Medical Press*, April 3, 1889.

NOTES AND QUERIES.

POLYDACTYLISM.

To the Editor of THE MEDICAL NEWS,

SIR: I desire to report the following case occurring in my practice, being another *exception* to Professor Brook's theory of polydactylism:

Female, white, aged ten years. Six fingers on right hand, six toes on right foot. Extra members articulating with metacarpal and metatarsal bones respectively. Well developed and moved with ease. Family history traced for three generations, and no deformity of any kind existed.

The above abnormality occurs very seldom in the white race; is very frequent among the lower African tribes.

It seems very strange that the origin of this excessive development should have been ascribed to the male by any one. Especially is it so in the light of the literature extant on the subject of the variation. I have not examined Professor Brook's observations or statistics on the subject, but from the many cases reported by men eminent in the profession, the theory seems to be without foundation. Very respectfully,

C. N. KAVANAUGH.

GAINESVILLE, TEXAS, April 19, 1889.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY, FOR THE TWO WEEKS ENDING APRIL 27, 1889.

BYRNES, JAMES C., *Passed Assistant Surgeon.*—Detached from special duty at Norfolk, Virginia, and ordered to the "Chicago."

HEFFENGER, A. C., *Passed Assistant Surgeon.*—Granted leave of absence for six months, with permission to leave the United States.

LEACH, PHILIP, *Passed Assistant Surgeon.*—Leave of absence extended six months, with permission to remain abroad.

LOWNDES, C. H. T., *Assistant Surgeon.*—Ordered to the Naval Academy, Annapolis, Maryland.

MCCORMICK, A. M. D., *Assistant Surgeon.*—Detached from the "Vermont," and ordered to the "Chicago."

WILSON, GEORGE B., *Assistant Surgeon.*—Detached from the Naval Hospital, Mare Island, and ordered to the "Iroquois."

CORDEIRO, F. J. B., *Passed Assistant Surgeon.*—Detached from the "Vandalia," and ordered to the Naval Hospital, Mare Island, California.

BRANSFORD, JOHN F., *Surgeon.*—Ordered to the "Iroquois."

STITT, EDWARD R., *Assistant Surgeon.*—Ordered to the Bureau of Medicine and Surgery, Washington, D. C.

FEREBER, N. M., *Surgeon.*—Ordered to the Naval Academy, Annapolis, Maryland, for examination of candidates for admission to the Academy.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 23 TO APRIL 29, 1889.

By direction of the Secretary of War, the retirement from active service, this date, by operation of law, of DAVID L. MAGRUDER, *Colonel and Surgeon*, under the provisions of the Act of Congress approved June 30, 1882, is announced.—Par. 4, *S. O. 94, A. G. O.*, April 23, 1889.

VOLLUM, EDWARD P., *Colonel and Surgeon.*—Promoted to Surgeon, with the rank of Colonel, from April 23, 1889.

WRIGHT, JOSEPH P., *Lieutenant-Colonel and Surgeon.*—Promoted to Surgeon, with the rank of Lieutenant-Colonel, from April 23, 1889.

WOODRUFF, EZRA, *Major and Surgeon.*—Promoted to Surgeon, with the rank of Major, from April 23, 1889.

Based on surgeon's certificate of disability, leave of absence for one month, with permission to leave the limits of the Department, is granted to *Surgeon* W. H. FORWOOD, Medical Department, Fort Snelling, Minnesota.—Par. 1, *S. O. 35, Headquarters Department of Dakota, St. Paul, Minnesota*, April 8, 1889.

HAVARD, VALERY, *Assistant Surgeon.*—Relieved from duty at Fort A. Lincoln, Dakota, and ordered to Fort Buford, Dakota.—Par. 29, *S. O. 95, A. G. O.*, April 24, 1889.

CRAMPTON, L. W., *Assistant Surgeon.*—Relieved from duty at Fort Bridger, Wyoming Territory, and ordered to Fort Lyon, Colorado.—Par. 29, *S. O. 95, A. G. O.*, April 24, 1889.

SPENCER, W. G., *Assistant Surgeon.*—Relieeed from duty at Fort Yates, Dakota, and ordered to Fort Bridger, Wyoming Territory.—Par. 29, *S. O. 95, A G. O*, April 24, 1889.

ROBERTSON, R. L., *Assistant Surgeon.*—Relieved from duty at Fort Buford, Dakota, and ordered to Fort A. Lincoln.—Par. 29, *S. O. 95, A. G. O.*, April 24, 1889.

By direction of the Secretary of War, EZRA WOODRUFF, *Captain and Assistant Surgeon*, is relieved from duty at Fort Missoula, Montana Territory, and will report in person to the commanding officer at Fort Monroe, Va., for temporary duty at that post.—Par. 14, *S. O. 92, A. G. O.*, April 20, 1889.

By direction of the Secretary of War, leave of absence for four months, on surgeon's certificate of disability, with permission to leave the Department of Texas, is granted to FREEMAN V. WALKER, *First Lieutenant and Assistant Surgeon.*—Par. 12, *S. O. 92, A. G. O.*, April 20, 1889.

ORIGINAL LECTURES.

THE PLANS AND PURPOSES OF THE JOHNS HOPKINS HOSPITAL.

An Address delivered at the opening of the Hospital, May 7, 1889.

BY JOHN S. BILLINGS, M.D.,
SURGEON U. S. ARMY.

THE third paragraph of the letter of instructions communicated by Johns Hopkins to the Trustees whom he had chosen to carry out his plans for a hospital in the city of Baltimore, states that "it is my wish that the plan . . . shall provide for a hospital which shall, in structure and arrangement, compare favorably with any other institution of like character in this country or in Europe." What do you suppose the writer was thinking of when he penned that sentence? Had he in view any definite ideal, any mental picture of the institution which he proposed to establish, or was it merely an expression of a desire to give to his city the best thing that could be devised? I have read that letter many times, have heard much of the ideas, hopes, and wishes which were expressed in the numerous conversations which preceded its preparation, and it seems to me that the writer had an ideal, and not a mere vague desire—an ideal which was no doubt somewhat misty, but which did not correspond to any existing hospital, and one which he did not attempt to define except in a few prominent points to which I shall presently refer. In most respects Johns Hopkins took the same course with his hospital which he did with his University, and deliberately refused to trammel with specific directions those whom he had chosen to carry out his plans; but this letter of instructions indicates, nevertheless, a conception of much more definite character, and one which had been the subject of more discussion and reflection, than his scheme for an university. Whether this be so or not, I am at all events sure that his Trustees have endeavored to comply with this letter of instructions, and to do so in the broadest and best sense of the words.

The beginning of the results we have before us to-day; results which even now are not confined to these particular aggregations of bricks and mortar, as will be presently explained, and the end of which will be, as we hope and believe, to make life happier for millions now living and yet unborn. Only those who took part in the early deliberations of those charged with this trust can fully realize the anxieties, the doubts, the manifold perplexities which at first attended their decisions and movements. Only one or two of them had any knowedge of hospital matters; most of them were business men, bankers, lawyers, judges, railway managers, men who knew something of the management of men and money, but who were now brought face to face with a new problem, viz., how to build, organize, and manage a hospital so that it should compare favorably with any other hospital in this country or in Europe.

To "compare favorably with," what does that mean? It is a peculiar phrase, which, coming from a shrewd business man and a member of the Society of Friends, signifies, I think, to excel, if possible; at all events that is the safest interpretation. And it was not this or that hospital which was to be surpassed or equalled, but all other hospitals in this country or in Europe; Africa, Asia and Australasia being put out of the question. It was a large contract.

The location was fixed—that had been done by Johns Hopkins, but they had to decide whether the structures to be erected should be temporary or permanent, of wood, brick or marble, in one large building or in many, and many other like points, before even the preparation of plans could be commenced. They followed the instructions of the donor and got advice; of which a great abundance was available. They visited the large hospitals of our eastern cities, employed five men, supposed to be skilled in hospitals, each to write an essay giving his plans and suggestions, published these essays in a book which had a wide circulation, and studied the criticisms and reviews to which this book gave rise.

Having duly considered the multifarious and widely divergent suggestions thus obtained, they finally selected one of the essay writers and asked him if he was satisfied with his own plans now that he had seen the others and the published criticisms upon them. He promptly said that he was not, whereupon they asked him to try again and do better. He set to work, aided by the architect of the Board, and the result was a set of sketch plans which he took abroad and obtained much counsel and criticism on, examining at the same time the model hospitals of Europe. He was much less satisfied with the sketch plans when he came back than he was when he started, and again the Building Committee, the architect, and himself reviewed the whole matter, and finally settled on the general arrangement which you will see to-day. Many details remained to be worked out; even the façades had not yet been designed; but the general scheme was settled, and the rest was comparatively easy for the time being.

Let us now for a few moments consider the broad general principles which governed the Trustees in the adoption of this plan. The first hospitals were established to give shelter and food to the sick poor, especially those who gathered in cities. Gradually physicians found that they could learn much in these aggregations of suffering and that they afforded the means of teaching others; but this last use of them is only about two hundred years old. Gradually, also, it came to be known that the knowledge thus obtained in the care of the sick poor was of use in treating the diseases of the well-to-do; and finally, within the last twenty-five years or so, people are beginning to find out that when they are afflicted with certain forms

of disease or injury they can be better treated in a properly appointed hospital than they can be in their own homes, no matter how costly or luxurious these may be. In the hospital they can have not only all the comforts of home, but more; not only skilled medical attendance and skilled nursing, but the use of many appliances and arrangements specially devised for the comfort and welfare of the sick which can hardly be found in any private house, and also freedom from noise and many petty annoyances, including in some cases too much sympathy and in others too little. This hospital, then, is to provide for the rich as well as for the poor; for those who can, and ought to, pay for the help given, as well as for those who cannot.

A second cardinal principle to be observed in such a hospital as this is, that it shall do as little harm as possible. A hospital may do harm by its foul air, by spreading contagious disease among its inmates, by neglect or carelessness of its nurses or attendants; and in years gone by hospitals have, no doubt, caused nearly as much sickness as they have relieved. This is now rarely the case, and in this hospital the arrangements for ventilation, isolation, and nursing are such as to do away entirely with this danger. There is another danger connected with free hospitals and dispensaries which is of quite a different kind and to which I can here only allude, namely, the danger of promoting negligence, shiftlessness, laziness, and vice by offering free relief from their consequences—the danger of pauperizing people. This is a danger connected with organization and management rather than with construction, and I can only say here that it has been foreseen and will be, as far as possible, guarded against.

The third principle to be kept in view in such a hospital as this is, that it should provide the means of giving medical instruction, for the sake of the sick in the institution as well as of those out of it. It is well known to those familiar with the subject that the sick in a hospital where medical instruction is given receive more constant, careful, and thoughtful attention than do those in a hospital where no such instruction is given. The clinical teacher must do his best; keen eyes will note every error in diagnosis, every failure in results of treatment. Moreover, the very act of teaching clarifies and crystallizes his own knowledge; in attempting to explain, the dark places become prominent and demand investigation, and hence it is that those cases which are lectured on receive the best treatment. I need say nothing here on the other side of the question, the value of properly trained physicians to the community and the necessity for hospital instruction in such training; Johns Hopkins understood all this and specially directed that "in all your arrangements in relation to this hospital you will bear constantly in mind that it is my wish and purpose that the institution shall ultimately form a part of the Medical School of the University."

Now there are medical schools and medical schools, and in obeying this direction of the donor the Trustees had to consider what sort of a medical school this school of the University was likely to be. As the majority of the Trustees were also Trustees of the University, they knew well the principles which underlie the organization of that institution and that the same principles would govern the organization of the medical department when that came to be taken in hand. One of these principles is the thorough teaching of that which is known, another is to increase that which is known, and to furnish the men and means for doing this. So also the hospital should not only teach the best methods of caring for the sick now known, but aim to increase knowledge and thus benefit the whole world by its diffusion. Another point which had to be kept in view was the direction of Mr. Hopkins that there should be established, "in connection with the hospital, a training school for female nurses, not only to care for the sick in the hospital but to benefit the whole community by supplying it with a class of trained and experienced nurses."

It is also highly desirable that a hospital of this kind should have connected with it a well-appointed dispensary for the treatment of those who need medical aid but not a bed in the hospital. Through such a dispensary much good can be done at small cost, the selection of proper patients for the hospital is facilitated, the means of medical investigation and teaching are greatly extended and the scope of the nursing system can be made to reach the poor and ignorant in their own homes.

The last point to which I shall refer, which was kept in view by the Trustees in deciding upon the plans, was the general appearance of the buildings and grounds.

Mr. Hopkins gave no specific directions as to the buildings, but he directed that the grounds should be properly enclosed by iron railings, and so laid out and planted as to be a solace to the sick and an ornament to the city, and it was evident that the buildings should be of the same character so far as their purpose would admit. It was therefore decided that, while no utility should be sacrificed for the sake of architectural ornament, and the main purpose which I have referred to should be fully worked out in the plans before any attention was paid to external appearance, it was fit and proper that the buildings should form an ornament to the city, and a suitable monument to the memory of the donor.

Bearing in mind, then, these main principles, to provide for the proper care of the sick, both rich and poor, to provide for the highest class of medical education, to increase and diffuse knowledge, to provide trained nurses for both hospital and city, to provide a dispensary, and to make the buildings and grounds ornamental and attractive, let us see how the problem has been thus far worked out.

I will begin with the arrangements for securing that article of prime necessity in a hospital, viz., pure air. Air supply and ventilation in this climate are inseparably connected with heating for a considerable portion of the year, for comfortable warmth must be secured, and on the means of doing this must largely depend the methods of ventilation and their success. The temperature of Baltimore may vary from 103° in the shade to 17° below zero F., hence its perfect hospital must be one which would answer for the tropics or for Northern Russia. To secure this, double walls, with air spaces, were given to the buildings, and a system of heating by the circulation of hot water was adopted for the wards. This system consists of central boilers, from which flow and return pipes extending beneath every building, connected with heating coils, of which there is one for every two beds in the ward above. The temperature in these coils can be exactly regulated to any temperature between 150° F. and the temperature of the external air by simply regulating the velocity of the flow of water by the valves at-

tached to each coil, and thus it is quite possible to give one pair of beds a temperature of 70° and another pair in the same room, at a little distance, a temperature of 60° F., to suit the needs of different cases. The 80,000 gallons of water contained in this heating apparatus go round and round, carrying heat from the furnaces to the wards, but every building has its own independent means of ventilation, and it is not possible to go from one ward into another without going into the open air on the way, so that foul air, if any forms, cannot spread from one building to another. Nevertheless, the buildings are so connected by corridors and underground tunnels that in passing from one to another there is no exposure to rain or snow, and the least possible to cold air, while the food is not exposed at all. This is not the place to describe the ventilation. I will only call your attention to the fact that the temperature of the incoming air by any bed is easily changed by turning a valve, while the quantity of air is not changed; to the arrangement for taking foul air from either the bottom or top of the ward, or from both, and to the fact that all this has been thoroughly tested during two winters and found to give the results hoped for.

One of the peculiarities of the wards is that all the service rooms are collected at the north end, leaving the south end free from obstruction and fully exposed to the sun, the end of the ward being a large bay window looking out on the central garden, and with a floor which can be warmed so that the patients, able to sit there, can be thoroughly comfortable. Another peculiarity of the sick wards is the arrangements for easy cleansing, and to prevent possible accumulations of dust in corners and crevices. Corners are to a great extent done away with, and easy curves given in their place, even at the junction of the floor and walls there is a curve instead of the usual right angle, and I advise you to look at it and see how it has been produced, for it ought to become fashionable, and take the place of the old mop-board in all well-constructed houses. So, also, the doors have not the usual moulding about the panels, giving recesses which it is almost impossible to clean.

One of the wards is especially arranged for cases which may be either contagious or offensive. In this building each patient is in a room by himself, and all these rooms open into a corridor through which the wind is always blowing. There are many details about this isolating ward which are worth looking at, but which I have not time now to refer to, and I must omit details about the pay ward, the octagon ward, and the peculiar fittings and conveniences of the kitchen, laundry, apothecaries' building, etc., for the same reason.

Let us pass now to the second object of the hospital, the giving means for higher medical education, and see what has been done for that. In the first place, there is a large amphitheatre with appended rooms for the reception of accidents and emergencies of all kinds. In the second place, provision is made for at least thirty students to reside constantly in the hospital and devote themselves under proper guidance to the study of disease and the practical care of the sick. It is intended that these places shall be open only to those who have had a thorough previous training, and who have shown themselves to be fitted to undertake this important part of their studies. As a rule, not more than five per cent. of medical graduates have had any opportunities worth speaking of to study and treat diseases in the living man when they receive their diplomas. They have to get this experience on their first patients, and sometimes the experience is rather hard—for both doctor and patient. This hospital has provided for the class of the medical school in the last year of their studies good rooms with bath-rooms, a dining-room, and other conveniences, and here they can be taught the actual daily work of a physician, for which all their previous studies are only preparatory. Many of the arrangements of the hospital have been constructed with reference to this instruction; it is a great laboratory for teaching the practical applications of the laws of hygiene to heating, ventilation, house drainage, and other sanitary matters. All pipes and traps are either exposed to view or can be seen by merely opening a door, and in the tunnel beneath the corridor you can study at your leisure the complicated and yet simple arrangement of pipes for gas, steam, water, sewage, etc., which are usually buried and remain a profound mystery to every one except the plumber, and often puzzle even him.

Closely connected with this subject of teaching is that of increasing our knowledge of the causes, symptoms, results, and treatment of disease; in fact, one cannot be thoroughly and well done without the other, and hence many of the provisions for the one are also useful for the other. For example, to go back to our system of heating and ventilation, there are many points connected with it which are destined for experimental work, to compare steam with hot-water heating, to determine the velocity of water at different temperatures, to compare ventilation by aspiration with that by propulsion, or by upward currents with those drawn downward.

One structure is very largely devoted to and fitted for experimental research, and that is the pathological laboratory, where the causes, processes, and results of disease are to be studied. Upon the results obtained in that laboratory may yet depend the saving of many lives, the relief of unspeakable agony, the warding off of pestilence from the city, and, to put it in a strictly business light, the value of real estate and the rate of taxation of this community. We are on the verge of great advances in our knowledge of the causes and methods of disease, and I feel sure that these will be only preliminary steps to far greater and better knowledge of how to prevent or to treat them than we now have. The probable length of life of the newborn infant to-day is not much more than half what it ought to be; the practical productive period of the life of our men and women is shortened and interrupted by unnecessary disease and suffering; but remember, if these things are to be amended, it is not merely by teaching old doctrines; we must open fresh windows and let in more light, so that we can see what these obstacles really are. It is in this work of discovery that it is hoped that this hospital will join hands with the University, and it is in this hope that some of the structures around you have been planned and provided.

A word now on the fourth object kept in view in this hospital, viz., the Training School for Nurses.

Some of you probably have had some personal experience of the difference between an educated, properly trained female nurse, and one of the old-fashioned sort, but if you have not, it would take much more time than I now have to describe it. I can only say, that in many

cases a competent trained nurse is as important to the success of treatment as a competent doctor, and that one of the greatest difficulties in treating well-to-do patients in their own homes in this city is the want of proper nurses. Affection and zeal may do much, but they cannot take the place of knowledge, and this kind of knowledge is not to be acquired in a day or in a month. It is a work best carried out by women, though not one woman in ten is fit for it, or should undertake it. But the woman who is fit for it, who has physical health and strength, sound sense, loving kindness, patience and tact, and who has been thoroughly taught the art of nursing the sick, with all its thousand details, has the power of doing good and increasing happiness to a degree which few others possess. In a properly conducted hospital ward she is a necessity, but her field of usefulness and helpfulness is by no means limited to that. She is needed outside the hospital, in the home of the rich to nurse and care for the sick; in the home of the poor, to teach prevention as well as nursing. To gather here such women, to have them thoroughly instructed, to furnish them with the attractive and comfortable home which they deserve, and to send them where they are most needed, with provision for their return when the work is done, is the object of the training school of this hospital.

For this purpose the Trustees have provided a large and handsome building, separated from the others, and exclusively appropriated to the female nurses, where each can have her own comfortable room, and where a common parlor, library, dining-room, bath-rooms, and, in short, the arrangements of a first-class hotel are provided for their use. Here also is a training-kitchen and a lecture-room to aid in the work of instruction. The intention is that when the nurse has finished her six or eight hours' tour of duty with the sick, she shall come quite away from the ward and all that pertains to it, and take her rest and recreation in a totally different atmosphere, and special effort has been made to have this home attractive and pleasant.

The fifth object which I mentioned as having been kept in view in the plan and construction of these buildings is the Dispensary. This is a large building on the north front, consisting of a large central waiting-room, surrounded by a number of smaller rooms for the use of the physicians and surgeons who are to examine and prescribe for the patients, and having bath-rooms, and a small apothecaries' establishment for the issue of the medicines ordered. This building is connected with the amphitheatre by a short covered corridor, and is specially arranged with reference to teaching. It, as well as the amphitheatre, is heated by steam instead of hot water, partly because they are not in constant use, and a rapid means of warming is desired, partly for the purpose already referred to of giving the means of experimental comparison of the two systems. The means of supply of fresh warm air in these two buildings, and of removing the air made impure by exhalations are somewat peculiar, and merit examination.

With regard to the architectural design and external appearance of the buildings, and the laying out and ornamentation of the grounds, I can only say that you must see and judge for yourselves whether Mr. Hopkins' wish that they should be an ornament to the city has been successfully complied with. So far as external ornamentation is concerned, it is confined almost entirely to the large buildings on the west, or Broadway, front, which it was felt should harmonize in style of decoration. These central buildings, consisting of the administration, with the one pay ward on either side, are constructed of pressed brick with ornamentation of a dark blue, fine-grained, hard, and durable stone, known as Cheat River stone, and of moulded terra-cotta of the color of the brick. The external designs for these, as for all the other buildings, were furnished by Messrs. Cabot & Chandler, of Boston, and I think we have good reason to be well satisfied with the results they have produced. The grounds are laid out and planted in accordance with designs furnished by Mr. E. W. Bowditch, of Boston.

As regards construction, I do not hesitate to affirm that these are the best built buildings of their kind in the world. The material is the best, the most skilled and careful workmen were employed, and, above all, the work received the most careful, conscientious, and intelligent supervision as it progressed. For this supervision we are indebted to Mr. John Marshall in the beginning and to Mr. William H. Leeke for the remainder and conclusion of the work; and we are also indebted to the latter for many valuable suggestions as to modes and details of finish which are so important in a hospital. The details of the complicated and extended system of heating, ventilation, and plumbing were designed and the work executed by Messrs. Bartlett, Hayward & Co., of this city. I should like to go on and mention a number of other names of persons who have done good work here, but want of time forbids. I will only say that these buildings embody the counsels and suggestions of many men and women in this country and abroad, but among them all there is no one who from the very beginning of the conception of the idea of this magnificent gift in the mind of Johns Hopkins down to this present moment who has had more to do with shaping the results, who has furnished more valuable suggestions, who is more thoroughly acquainted with all that has been done, and why it has been done, who has worked so unselfishly, and who more deserves honor in this connection than the President of the Board and Chairman of the Building Committee through the whole progress of the work, Mr. Francis T. King.

Briefly and incompletely as I have sketched these salient points of the plans and purposes of this hospital, I hope I have, nevertheless, shown you that it is intended for other purposes besides providing shelter, food, and drugs for the sick. In saying this I have not the least wish to undervalue or disparage those institutions which do make this their main or only object. There is abundant need of their existence and work also; but this institution should not be judged by the rules which apply to them; it cannot be managed after their fashion: if it does not produce results different from theirs it is a fallure and the expenditure upon it a mistake.

Thus far I have been speaking of the buildings only, and trying to give you some idea of the motives which led to their being as they are, and what they are, and not otherwise. From the beginning, however, it has been recognized that the buildings and machinery are only means to an ends, tools which must be handled by skilled workmen to produce the desired result; and throughout all these years of planning and building, the question of organization and of the sort of men and women who were to use and work with these things has

not been lost sight of. It is true that no attempts were made to select and engage individual members of the hospital staff until quite recently; but there was, nevertheless, a tolerably definite conception as to the ideas, mode of work, character, and wants of those who are to constitute this staff, and when the time came for selecting, it was made by this standard.

On the philanthropic, social, and religious aspects of this great trust I do not propose to touch, but I wish to say a very few words of the hopes and wishes of scientific men and physicians with regard to it. From the time of the first announcement of the Hopkins bequests to the present, these men, all over the world, have been keenly interested in the plans and methods adopted in carrying them out. Whenever and wherever the problems of higher medical education have been discussed within the last ten years, there has been speculation as to the probable course of the Johns Hopkins medical department, and the influence it would have upon the standard. I may even say that some of this influence has been exerted in advance, has been discounted, as it were, for the plans of this hospital have stimulated changes in some of our best medical schools, and have been copied with more or less modification in some of our latest hospitals.

What is it, then, that the physicians want? Is it more physicians, more family practitioners, more surgeons, more specialists? Not at all. They know very well that there is no danger that the supply will not be equal to the demand; when they become overburdened with practice they do not at present find it difficult to obtain assistants; they have no fear lest the seventy or eighty medical schools of this country should fail to produce a sufficient number of medical practitioners to meet the wants of our increasing population; and they know also that the medical schools of Great Britain and Germany are sending to us quite as much of their product as we can conveniently dispose of. They hope that the Hopkins medical school and hospital will do two things. The first is, that it will demand of those who propose to become its students evidence that they have a sound basis of preliminary education before they commence, and that its standard in this respect shall be little below that of the requirements for granting the degree of bachelor of arts in the University. It is hoped that the men thus selected will go through a carefully graded course of study, including actual work in properly fitted laboratories, and that after this they will be brought into contact with the sick, and thus obtain practical experience of the duties and responsibilities of the practitioner of medicine before they offer their services as such to the public.

So much our physicians desire of every medical school, for the sake of the honor and dignity of the profession, and for the good of the public, and they desire especially that this school shall form an example to which they can point as showing how medical education should be conducted, and what should be required of the candidate for the degree of doctor of medicine.

The very general interest in the combined Hopkins trusts felt by physicians and scientific men not only of this country but of the whole civilized world, is largely due to the belief that the relations which will here exist and be maintained between the University as a whole and its medical department, of which this hospital is to be an important part, will be close and intimate, so that the true University spirit will pervade, stimulate, and encourage the hospital work. In this country medical schools have either had no connection with Universities properly so called, or the connection has been slight and nominal, such as depends upon the formal conferring of medical degrees by the University. Here, however, through the influence of the biological department, there are secured common interests and mutual influence, and it is hoped therefore, that the necessary details of technological instruction will be arranged in accordance with and subordinate to the broad principles of scientific culture upon which this University is organized.

It is because it is believed that this will be the case that there is a widespread hope and expectation that these combined institutions will endeavor to produce investigators as well as practitioners, to give to the world men who can not only sail by the old charts, but who can make new and better ones for the use of others. This can only be done where the professors and teachers are themselves seeking to increase knowledge, and doing this for the sake of the knowledge itself;—and hence it is supposed that from this hospital will issue papers and reports giving accounts of advances in, and of new methods of acquiring knowledge, obtained in its wards and laboratories, and that thus all scientific men and all physicians shall share in the benefits of the work actually done within these walls. But, however interesting and valuable this work may be in itself, it is of secondary importance to the future of science and medicine, and to the world at large, in comparison with the production of trained investigators, full of enthusiasm, and imbued with the spirit of scientific research, who will spread the influence of such training far and wide. It is to young men thus fitted for the work that we look for the solution of some of the myriad problems which now confront the biologist and the physician.

Do I seem to ask too much? to be too sanguine as to what human thought, and study, and skill may accomplish? to forget that there is one event unto all; that the shadow of pain and death comes on the wise man as on the fool? I have two answers. As surely as our improved methods of prevention and treatment, based on the advances in knowledge of the last fifty years, have already extended the average duration of life in civilized countries nearly five years, have prolonged thousands of useful and productive lives, and have done away with the indescribable agonies of the pre-anæsthetic period, so surely we are on the verge of still greater advances, especially in the prevention of infectious and contagious disease, in the resources of surgery against deformities and morbid growths, and in the mitigation of suffering due to causes which cannot be wholly removed. But the second answer is more important, and it is this: It is our duty to try to increase and diffuse knowledge according to the means and opportunities which we have, and not to rest idle because we cannot certainly foresee that we shall reap where we have strewn. "It is not incumbent on thee to finish the work, but thou must not therefore depart from it," says the Talmud, and "Of him to whom much is given much shall be required," says the Scripture.

To you, the officers of this institution, and to you, men and women of Baltimore, there is now given the opportunity of giving powerful aid in this increase and diffu-

sion of knowledge of the laws of human life, disease, and death. Surely, those who are working in the wards and laboratories of the hospital and University will do their best; surely, also, the citizens of this great city of a great nation, which at no distant day will take the lead in scientific work, will encourage, sustain, and sympathize with these workers. I would have this hospital become famous, not for fame's sake, but because this will be evidence of the good work which has been done in it; but we must not be impatient. There are difficulties to be overcome, delays which must be submitted to. We cannot at once have the medical school which is essential to the plan which I have sketched; but there is plenty to do for the present, and I am certain that in time all these present obstacles to full development will be happily overcome.

Success in this, as in all other enterprises in this world, is to be obtained by unselfish work for the good of others, by wise counsel, by coöperation, and by persistent effort.

A hospital is a living organism, made up of many different parts, having different functions, but all these must be in due proportion and relation to each other, and to the environment, to produce the desired general results. The stream of life which runs through it is incessantly changing; patients and nurses and doctors come and go; to-day it has to deal with the results of an epidemic, to-morrow with those of an explosion or a fire; the reputation of its physicians or surgeons attracts those suffering from a particular form of disease, and as the one changes so do the others. Its work is never done; its equipment is never complete; it is always in need of new means of diagnosis, of new instruments and medicines; it is to try all things and hold fast to that which is good.

"Et quoniam variant morbi, variabimus artes."

It has been said that "hospitals are in some sort the measure of the civilization of a people, but a hospital of this kind should be more than an index. It should be an active force in the community in which it is placed. When the mediæval priest established in each great city in France a Hôtel Dieu, a place for God's hospitality, it was in the interests of charity as he understood it, including both the helping of the sick poor and the affording to those who were neither sick nor poor an opportunity and a stimulus to help their fellow-men; and doubtless the cause of humanity and religion was advanced more by the effect on the givers than on the receivers. It is the old lesson so often expounded, apparently so simple and yet so hard to learn, that true happiness lies in helping others; that it is more blessed to give than to receive.

In some respects we to-day have a much wider outlook than the men of a thousand years ago. This hospital is designed, as I have told you, to advance medical science as well as to give relief to the sick poor, but the fundamental motive is the same—to help others.

We have here the beginning of an institution which shall endure long after the speakers and the audience of to-day shall have finished their life-work and have passed away. Founded in the interests of suffering humanity, intimately connected with a great university, amply provided with what is at present known to be essential to its work, we have every reason to predict for it a long and prosperous career, with steadily progressing improvement in its organization and methods, and enlargement of its activity and influence.

Let us hope that before the last sands have run out from beneath the feet of the years of the nineteenth century it will have become a model of its kind, and that upon the centennial of its anniversary it will be a hospital which shall still compare favorably, not only in structure and arrangement, but also in results achieved, with any other institution of like character in existence.

THE RELATIONS OF THE TUBERCLE BACILLUS TO THE EARLY DIAGNOSIS AND TO THE PROGNOSIS OF PHTHISIS.[1]

BY J. WEST ROOSEVELT, M.D.,
VISITING PHYSICIAN TO BELLEVUE AND ROOSEVELT HOSPITALS, NEW YORK.

THE subject assigned to me to-night is one regarding which but little need be said. As I understand the purpose of this meeting, it is more to direct and call forth discussion upon the whole subject of phthisis, than to attempt to lay before you any new views, that the papers are read. For this end I shall take a pretty positive stand in my short paper, hoping that those who discuss it will thus be induced more fully to express their approval or dissent.

The first division of my subject is the value of the discovery of the bacillus tuberculosis in the sputum of patients in the early diagnosis of phthisis. So often we have presented a problem like the following. A young man is engaged in a business of such a nature that his presence is absolutely necessary in order successfully to advance it. He works hard; after a while he begins to lose flesh a little and has a cough, with perhaps slight expectoration. He consults us, and asks whether or not he has phthisis. Perhaps some of his relations may have had it. Now, should we answer yes, and recommend a change of residence, it means that his business prospects are ruined. He may have to commence life again. If we are right, all is well; but, if wrong, we have done a grave injury. On the other hand, if we say he has no phthisis, and are wrong, his life may be the price of our blunder.

How should we go to work in order to answer the question? We carefully ask about the history; we examine the chest; we examine the sputum, perhaps a number of times; we may find the bacillus in the sputum, and then all doubt is removed. But, suppose we do not; what then? Can we say that phthisis does not exist? Decidedly, no. It must be remembered that in phthisis we often have no tubercle which is situated so as to be connected with the air-passages. It is, indeed, possible for an extensive tubercular deposit to occur, and yet no

[1] Read before the New York Academy of Medicine, May 2, 1889.

bacilli be discharged. It is also possible for so much bronchial discharge to exist that the bacillus may be overlooked in the large quantity of expectoration. The search for a needle in a haystack is usually thought unprofitable, and it is not unlike the search for a few bacilli in a number of ounces of expectoration. Surely none would deny, in a given case, the existence of phthisis because the bacillus could not be found. Even though very many careful examinations be made and no bacilli be discovered, yet this evidence against the diagnosis of phthisis is but slight. Of course, the bacillus as positive evidence is invaluable. We must not allow too much time to go by while waiting to find the microbe, or the patient may lose his life before we make up our minds.

Before going further I wish to remind you of some points regarding the anatomy of the lesions of phthisis, and the manner in which the bacilli are distributed in the lung tissue. Phthisis I define as a more or less complex disease, depending upon the growth of the bacillus and consequent tubercle formation. As seen in New York, there are a number of cases in which the lesion, until near the end, seems to consist of the deposit of tubercles, beginning in the upper lobes and gradually spreading and involving the lower. There is also some pleurisy and some bronchitis. Now in these cases there is not much tendency for the tubercles to break down early in the disease. There being practically no pulmonary consolidation in these cases, nothing at first but a few scattered tubercular nodules, the physical signs are of little value. It is possible for this form of phthisis to progress very far, yet give no distinctive signs. Unfortunately, for the reason that scattered tubercles constitute the lesion, and that these do not early break down and empty their bacilli into the bronchial secretion, the detection of the latter is frequently impossible at the very time they would be of the most value.

In another form of phthisis we have with the tubercle deposit pneumonia, coagulation-necrosis, marked bronchitis, etc. Practically, this form gives signs, owing to the consolidation, earlier than the other. It also breaks down over a greater extent of the lungs. The bacilli are frequently and abundantly discharged.

It may be said that those cases presenting the greatest difficulties for diagnosis, disregarding the bacillus, present also the greatest difficulties in finding the bacillus. In many of them it is not to be found, and we must make the diagnosis mainly from the history, and to a lesser degree from the physical signs.

As to the prognostic value of the bacillus it can hardly be said to have any. Patients going rapidly down hill will be found whose expectoration contains but few bacilli, and on the other hand large numbers may be found in the sputa of those whose disease is advancing slowly, if at all. It is only a question of the freedom with which cheesy matter is emptied into the bronchi. Strangely enough, there is a decided tendency for many to regard the bacilli which are discharged as a measure of the disease, as if they and not the ones growing in the patient did the harm. Hence, we read of "diminution in the number of the bacilli" under varied treatments as a symptom of improvement. It may or may not be such a symptom; at best it is a most delusive one. Watching for it and laying stress on it has done one great harm: it has given a longer life to the various so-called "antiseptic methods" of treatment. Of course, the word "antiseptic" is here used as meaning destructive to bacillary life.

"A strong solution of, *e.g.*, carbolic acid kills bacilli after some hours; therefore, give very small doses of that agent (doses so small as to be when diluted with a bulk of fluid equal to that of the blood entirely harmless to the microbes) and thus cure the phthisis." This is the real basis of reasoning for all such treatment, and how often have we heard in regard to each of the new antiseptic methods that "the cough and expectoration and night-sweats improved; the bacilli were reduced in numbers," and to this should usually be added, the patients died!

Now the fact that bacilli vary greatly in numbers from time to time has added somewhat to the apparent value of the many different kinds of treatment. I am aware of the fact that I am somewhat exceeding the bounds of my subject, but the time has come for a protest to be made against the administration of poisons to unfortunate people in the so-called "antiseptic treatment" of phthisis. To do this and to call the methods by which the particular poisons have so far been chosen "scientific," is possibly to injure the patient, but certainly to exhibit a peculiar idea of what constitutes science.

I would not for a moment be understood as objecting to the trial of any non-injurious treatment for phthisis. It would be reasonable to try an infusion of cobwebs, such as was of old used in malaria. I protest, however, against the giving of any antiseptics tested as now and calling it rational. While the complex body cells are easier to kill than the more simply constructed bacilli, it does not seem very encouraging to try to kill the latter while leaving the former untouched. It is probable that nourishing the phagocytes is better than trying to kill the bacilli. It is possible that empirically something may be found capable of acting as a specific bacillary poison, but no evidence has yet been obtained that such a substance exists, nor is it likely to be obtained by the present crude methods.

The propositions set forth in this paper are these:

1. The bacillus tuberculosis is of great positive but no negative value in diagnosis.

2. In prognosis the bacillus is of but little value.

3. In both diagnosis and prognosis quite as much depends upon the careful study of the case, as a whole, as if there were no bacilli concerned in producing the disease; except that a diagnosis is sometimes rendered positive, which would otherwise be doubtful, by finding the microbe.

In concluding the paper, I can only say that it seems a pity to have taken up your time to make such absolutely trite remarks.

Before any discussion takes place I wish it understood that I say nothing about any phthisis not of bacillary origin. We see such cases very rarely in New York. What I refer to is the so-called "catarrhal phthisis" and "tubercular phthisis," both diseases caused by the bacillus of Koch.

THE USE OF BORAX IN THE TREATMENT OF EPILEPSY.

BY HORACE G. HILL, M.D.,
OF PHILADELPHIA.

IN November, 1884, Mary ——, aged sixteen, was brought to me, with the following history: Her father had always been considered a delicate man, and died when about thirty-two years of age, from some form of spinal disease. Her mother is still living, and, with the exception of attacks of hepatic colic, has been in fairly good health. She is, however, of decidedly neurotic temperament, and subject to severe headaches from slight causes. One uncle, on the mother's side, was an epileptic from early childhood, and died at sixteen years of age, from burns received by falling into a fire during a convulsion. Another uncle on the same side is living, but has for many years been a confirmed epileptic. Up to the age of seven years the patient appeared to be a healthy child; but at that time attacks of *petit mal* first showed themselves, recurring at progressively shorter intervals. One year later the attacks of *grand mal* were developed. Menstruation was established at fourteen, but was irregular in interval and amount, and the recurrence of the period was always attended by increased frequency and severity of the epileptic seizures. Few days passed without one or more convulsions, and frequently four or five of the major attacks and numerous minor attacks would occur within twenty-four hours. In addition to the treatment of her family physician, she had consulted three specialists in Philadelphia and New York. The one placed her upon a combination of the three bromides; the second upon nitroglycerine; and the third upon hydrobromic acid. In each instance the use of the remedy was followed by some temporary improvement, in that the number of seizures was lessened, but in each instance, notwithstanding the utmost care in following the line of treatment marked out, she relapsed after a few months.

She was, when I first saw her, of large frame, and with a fair amount of fat. The flesh was flabby, the complexion decidedly chlorotic, and the eyes lacked expression. She was very reticent, without animation, afraid of company, and very distrustful of herself. Mental development was much retarded, it being impossible for her to fix her attention upon anything requiring concentration. She was easily fatigued by either mental or physical exertion. The appetite was capricious, and the bowels constipated. She suffered frequently from obstinate frontal headache, sometimes attended by nausea and vomiting. The circulation was sluggish, and cold feet a constant symptom. Urine analysis showed an excess of phosphates, but nothing else abnormal. Menstruation was irregular and scanty, sometimes recurring every two weeks. There was the usual bromide acne upon the face and chest. The epileptic attacks (the frequency of which has been before stated) were largely nocturnal, but there was no absolute rule in this respect.

Treatment.—In taking charge of the case, the great importance of proper food, sufficient time for meals, and thorough mastication, was impressed upon the mother, and the diet was regulated by a definite diet-list which excluded all rich and indigestible dishes, and limited the daily quantity of nitrogenous food. Directions were given regarding bathing, friction to the skin, and mental and physical exercise pushed to a point involving slight fatigue. The bowels were kept in normal condition by a suitable laxative. As the medicinal portion of her treatment, she was placed upon nickel bromide, a remedy which had been recently introduced, and which was highly recommended where the usual bromides failed. Fowler's solution in moderate doses was conjoined.

This treatment was continued one year, during which time the attacks ranged from two to nine per month. At the end of that time the stomach became intolerant, and the remedy had to be discontinued. Well-marked and undoubted improvement had occurred, but the nickel bromide acted as a depressant, and when it was dropped it became necessary to substitute active tonic measures. Under tonic treatment, but with no change in diet or hygienic surroundings, the number of attacks was increased to thirteen per month.

It was at this time, April, 1886, that I chanced to find in the *Boston Medical and Surgical Journal* an article written by Dr. Charles F. Folsom, in which he claimed that borax is of great value in some cases where the bromides fail. The usual remedies for epilepsy had been tried in this case, and had not succeeded to anything like the desired degree. As it was impossible to leave the patient in the condition in which she was at that time, I adopted the suggestion, and resolved to give so simple a remedy a fair trial. I must confess that I had little hope of good results. Other rules remained as before; but instead of the nickel bromide I substituted borax gr. x, with tr. cardamom. comp. ʒj, in water, one and a half hours after meals.

Improvement was immediate and marked. Four attacks occurred within the first ten days, and before she was well under the influence of the drug. Then followed a period of three months with no seizures at all.

This borax treatment has now been continued for three full years, and the results are as follows: The attacks have greatly diminished, both in number and severity. There have been periods of complete immunity, extending over several months at a time, a thing before unknown and unhoped for. When attacks did occur there were but one or two during the month, usually to be traced to some slight error in the diet, or to hastily eaten meals. The greatest number of attacks in any one month has been four. There has been uninterrupted physical and mental development, and instead of the flabby, chlorotic, stupid girl, she has become a robust and vigorous woman. Menstruation is regular in interval and amount, and unattended by neurotic disturbances. Headache has almost entirely disappeared. She no longer shuns society, but mingles with others freely and without distrust of herself. Her judgment can be relied on. Under the instruction of a private tutor she is rapidly making up for lost time. It is now six months since the last attack, and her mother considers her, to all intents and purposes, well.

In narrating the history of this case, it is not the purpose of the writer to claim any brilliant results. It will be conceded that the family history, the mode of development of the disease, the time of life at which it developed, and the failure of the most approved methods of treatment to make any marked impression upon the case, all combined to render the prognosis unfavorable in the extreme. And with this poor outlook it is enough to claim that the disease, which had formerly controlled the physical, moral, and mental life, has been thoroughly subordinated and the opportunity offered for normal growth in all directions. This has undoubtedly been achieved.

The remedy is but little known, and rarely used in the treatment of epilepsy. In standard works bearing upon the subject allusion is made to it in scanty terms, or, as is far more frequently the case, it is not named at all. It is not probable that it will ever be used where the bromides are effective, as they undoubtedly are in the majority of cases, but it seems to be of special utility where the bromides prove useless and the patient is in danger of being left, comparatively without help, to the deleterious influence of the disease.

This remedy possesses advantages in that it does not act a depressant, and, when given in the manner indicated, does not cause gastric disturbance. Occasionally a slight, scaly eruption is noticed, which can be readily controlled by small doses of Fowler's solution. The dose may be increased to gr. xx, though in the case reported it has never been necessary to exceed the half of this quantity.

I have had under observation for the past four months another patient with whom also the bromides disagree. Under similar treatment there has already been great improvement, but it is, of course, too soon to report anything of definite value.

3416 BARING STREET.

ASTHMA DUE TO FUNCTIONAL DERANGEMENT OF THE STOMACH;

With Remarks upon Treatment.

BY W. W. VAN VALZAH, M.D.,
AND
CHARLES R. CRANDALL, M.D.,
OF NEW YORK

THE following case of bronchial asthma is one of more than usual interest, owing to its causation, severity, and duration. It illustrates, in the most marked degree, to what extent indigestible foods, acidity and fermentation, distention of the stomach and bowels with gases, and the absorption of morbid material into the blood, may cause prolonged and terrible asthma in one predisposed thereto.

This form of causation is far more common than is generally believed, and has not received the attention it deserves. While nearly all authorities admit that paroxysms of asthma are due to some reflex irritation, at the same time but little stress has yet been laid by any of them upon the fact that the seat of trouble is most commonly located in the stomach, or in the bowels, or in both. One distinguished author of an elaborate work on *The Practice of Medicine*, simply mentions, in a chapter eleven pages long, on asthma, that "indigestion, in some cases, proves an exciting cause oftener than anything else." Whereas, it would have been more nearly correct to say that improper food and functional or catarrhal disease of the stomach and bowels are more often the cause of paroxysms of asthma than *all* things else. With a view to the need of impressing this important truth, it is believed that there is no necessity of apologizing for presenting an illustrative case, and a few practical details of successful treatment that have now been applied to many cases.

CASE.—Mr. L., aged forty-eight years; manufacturer and merchant. In early life he was considered frail and not well constituted. In boyhood he lived on a farm but was not well; suffered more or less from fever and ague. At the age of nineteen he went into the army, but was soon taken sick; army food seriously affected his stomach and bowels, and later he had typhoid fever. He was subsequently wounded in a battle and was sent North for treatment; here he was stationed at David's Island, where a good climate, plenty of exercise, and a meat diet restored his health, and he increased in weight to 180 pounds. After serving four years in the army he went to Westfield, Mass., and engaged in manufacturing. His health remained fairly good for three years, at the end of which time bronchitis developed and was accompanied by more or less asthma. At the same time he began to suffer from

indigestion, flatulence, and pain in his bowels, all of which obliged him to live on a light, restricted diet. The asthmatic attacks gradually increased from an occasional slight attack quickly relieved, to those lasting six weeks at a time, which nothing would relieve. During these long periods he was obliged to sit up all night, using every available remedy and receiving the best treatment then known. Under such suffering his general health declined, and his weight was reduced to 140 pounds. Finally, he had an attack of pneumonia, which prostrated him still more. When sufficiently recovered he took a trip to Florida and was gone four months, but was not benefited. Then he gave up business and went to New York for treatment at the hands of the most renowned men in the profession.

Despite the best treatment to be had, asthma prevailed in its worst form, and his sufferings became so severe that it was thought he would die. In this condition he was taken to Montclair, N. J., where the climate agreed with him and improvement ensued. It is worthy of note that during all this time he had pain in his stomach and over the liver, and suffered from indigestion. These symptoms were, however, considered secondary instead of primary. After improvement took place he went home to Westfield, only to be stricken again with the severest asthmatic paroxysms. Later he started for Maryland, hoping to obtain relief, but grew rapidly worse, and returned to New Brunswick, N. J. Here he found comparative comfort and settled down for a year. Having, as he supposed, recovered as far as possible, he returned again to Westfield, but on the second day was stricken with even greater severity. For three days he coughed, raised, struggled, and gasped, until he almost died, aud longed for death to relieve him. In this condition he was taken from home to New Brunswick, N. J., almost dying on the way, but was rewarded with gradual relief. These attacks were so severe that they resisted every known remedy and the best medical skill that could be obtained.

Finally, in the year 1874, he went to Denver, Colorado, to live, and at first was benefited by the change. After a time his chronic bronchitis seemed to grow worse, but the asthmatic paroxysms were less frequent, and at no time was he ever free from suffering. As a rule, he has had from three to ten paroxysms a day, and has been obliged to make daily use of pastiles and sedatives. As Denver became more densely settled, he felt the ill effects of the increased amount of dust and smoke, and was compelled to make frequent changes. Usually he spent the spring and fall at Manitou Springs and there found some relief, but never immunity. While at these springs he drank copious quantities of alkaline waters, the general effect of which was beneficial. It was his practice in the summer months to go to Estes Park, in Colorado, 7500 feet above the sea, and there spend several weeks. In this place he also found some relief; but, nevertheless, had some of the worst attacks he ever had; these, too, in the supposed most favorable climate in the world for asthmatics. He was never able to see that high altitudes were specially beneficial to him, but in a general way the Colorado climate agreed with him better than an eastern climate, although in the former he experienced at times the worst suffering he ever knew.

It is to be borne in mind that at no time was he free from bronchitis and asthma; he had asthmatic breathing all the time and extreme paroxysms every day and night, which he had to relieve by burning pastiles and taking sedatives, mostly bromides and chloral. Every little while he would have terrible asthmatic spasms, during which it seemed as if he must die. The slightest change in the atmosphere, the irritation of smoke and dust, the eating of certain foods, and even peculiarities of soil, would throw him into a paroxysm. Upon one occasion, when with a party of friends in the mountains, he had such suffering that he was given up to die and the party went into a consideration as to how they should get his remains back to Denver. At another time he was riding with a friend and was taken in a similar manner. He soon became helpless and speechless, struggled violently for breath, grew purple in his face, and the blood flowed from his nose. The friend, frightened beyond measure because of the apparent imminence of death, began to discuss the ways and means of clearing himself of the possible charge of murder. On still another occasion a paroxysm came on, preceded by pain and contraction in the bowels. The asthmatic symptoms became of the most agonizing character, accompanied by blueness of the face, nose-bleed, and complete prostration. The spasm in the abdomen increased until there followed functional paralysis and complete loss of power over both bowels and bladder and it seemed as if he must die in a short time. When *in extremis* and about breathing his last, the spasm relaxed and he gradually regained himself. During these severe attacks there was always the violent wheezing and gasping for breath, the helplessness and speechlessness, the turning black in the face, the flowing of blood from his nose, and he would seemingly go to death's door. The violent struggles for breath would bring on heart failure, cyanosed color of the face and head, cold extremities, and every other indication of extreme depression and irregularity of circulation. Prolonged suffering and the almost constant use of sedatives tended to break down his nervous system and impair the action of his mind. He became very weak, his mental faculties began to fail, as shown by dulness of mind and loss of memory. So constant had been his asthma and suffering that he had come to be known as "the worst asthmatic in Colorado."

All this, despite the fact that he was supposed to be living in the most favorable climate in the world, was using every remedy and means that promised relief, had had the advice of about twenty different physicians, many of whom were the most celebrated in the land and some of the number renowned specialists. An intensely interesting feature of this history is the fact that from first to last he suffered from indigestion, flatulence, and great distention from gas, but its significance was never recognized.

Every severe attack was preceded and accompanied by distress and fulness in the stomach and bowels, and yet these were supposed to be of secondary importance.

When he came under treatment his condition was most pitiable. His skin was pale and dingy, he looked tired and exhausted, his chest was drawn out of shape from so much struggle for breath. He only weighed 128 pounds, and he was so weak that he could walk but a short distance. He was having several asthmatic paroxysms both day and night, and was expectorating about a teacupful of tough, frothy mucus in twenty-four hours.

Physical examination showed that he was greatly wasted in flesh and his chest was more or less out of shape. Auscultation detected the presence of coarse sonorous and fine sibilant râles, seemingly in every bronchial tube and air-cell. The breathing was emphatically asthmatic in all of its characteristics. Percussion note was hyper-resonant all over the chest both posteriorly and anteriorly. The heart was found to be so weak that its sounds were scarcely audible; it appeared to be worn out and feeble from prolonged overwork. Abdominal inspection and palpation revealed the presence of a large amount of gas in the intestine and tenderness over the stomach and lower margin of the liver.

Microscopic study of the blood showed that the red corpuscles were pale, shrunken, and poorly nourished, and that its integrity was further impaired by the presence of a great amount of fibrous filaments. These were beginning to degenerate and mass together without definite outline, as is the case where the fibrous structure of the bronchial tubes is about to break down. There was present also a moderate quantity of yeast germs, the product of fermentation in the stomach and bowels.

The sputa amounted to nearly a teacupful in twenty-four hours, and in consistency was thick, jelly-like, and frothy. By microscopic examination it was found to contain shreds of stringy mucus, epithelia, numerous cells and crystals, and other morbid material. It was in all respects typical of the advanced stage of the worst form of asthma.

Urinary analysis gave important and interesting data. The amount passed was very scanty, so much so that the patient had noticed the fact. It was very heavy, having a specific gravity of 1034; there was a great excess of biliary coloring matter and phosphates. The reaction was highly acid; there was no sugar or albumin. In a general way the urine tended to show that the patient's digestion was greatly out of order, and that there was excessive nerve waste.

In order to find out what to do, and to obtain a clear conception of existing conditions, it was necessary to "work up the case" with exceeding care. Of course, it was easy enough to diagnose bronchial asthma, because every characteristic of the disease was on constant exhibition. The greater object, however, was to diagnose the cause and to understand thoroughly the relations existing between cause and effect. Therefore, besides investigating all of the signs and symptoms of the disease, as is ordinarily done, the more strictly analytic method, consisting of a study of the products of the system, was adopted. This necessitated, as already seen, a microscopic study of the blood and sputa, and repeated examinations of the quantity and character of the urine. These methods, *diligently and persistently employed*, were the only ones that could afford a clear, accurate, and definite understanding of the extent and manner the organs were performing their functions. It was, indeed, the *only accurate means of determining* to what extent the stomach was digesting food; to what degree the liver and kidneys were doing their work; and just what quality of blood was being made. The information thus obtained from the history and subjective symptoms, and by a repeated study of the blood, urine, and physical signs, tended to show that the real source of asthma was in his stomach. Not only that, but the evidence so obtained also tended to verify the fact, noted in many similar cases, that asthma, with all its attendant spasms and suffering, is more often due to functional or catarrhal disease of the stomach or bowels, or both, than to anything else. Like all other chronic diseases, it is dependent upon conditions constantly prevailing, and, in the majority of instances, these are seated in the gastro-intestinal canal, where, as has been said, "the health of the whole body is tempered." Moreover, as will be seen farther along, the result of the treatment was to sustain the conclusions deduced from the history of the case and the methods of diagnosis that were employed.

Having thus fixed upon the seat of the disease, the first rational thing to do in the line of treatment was to obviate one of the evident causes by dispensing with all fermentable foods, such as vegetable, starchy, and saccharine articles, substituting those that would not readily ferment, and employing remedies calculated to restore normal digestion. Past experience in many similar cases had established the fact that the food best calculated to meet this indication was an animal diet in the form of prepared muscle pulp of beef.

Consequently the patient was directed to avoid the fermentable articles of food mentioned above, and to limit himself for a time to a strictly meat diet, consisting of beefsteaks, mutton-chops, and the tender meat of game and poultry. Later he took the prepared muscle pulp, of which he soon ate large quantities with a good appetite and keen relish. With a view to aiding temporarily the stomach to digest his albuminoid diet, he was given a few grains of pepsine after each meal. The change of diet was promptly followed by a disappearance of acidity and flatulence, and distention of his stomach and bowels, and as soon as this was accomplished he began to note more comfort in his breathing. As might be expected, the old asth-

matic habit was rather loath to leave, especially in New York climate. It was necessary, therefore, at first to relieve his urgent spasmodic symptoms, and so he was given a combination of ethereal oil and chloroform, fifteen minims of the former and two of the latter, to be taken as he needed. In a short time, however, he became so generally relieved that he was enabled to dispense with sedatives and to sleep comfortably all night—a thing he had not done for many years.

As was stated before, his nervous system was worn out from prolonged suffering, the fibrous structure of his lungs had undergone great thickening, and his heart was so weak that its sounds were almost imperceptible. To meet these indications he was given a supporting alterative tonic, composed of cinchona, damiana, and nux vomica, to which were added five grains of English iodide of potassium. For a direct heart tonic he was prescribed one-sixtieth of a grain of digitalin every four hours. Inasmuch as he grew stronger rapidly, digitalin was soon withdrawn. He had taken all of these remedies before, as well as many others, but to no avail, for the reason that the real cause of his asthma had never been removed.

It is interesting to note, too, that none of the usual "asthmatic sedatives" and expectorant remedies, like grindelia, opium, bromides, chloral, lobelia, squills, and ipecac, were employed from first to last. Medicines were adhered to only in so far as they relieved spasmodic action, improved the powers of digestion, sustained the action of the heart, and increased the power of the nervous system. The conviction adhered to was that a removal of the cause would be followed by a removal of the effect, and time verified both the conviction and the prophecy.

In addition to the few remedies used he was advised to drink a pint of hot water two hours before each meal and upon going to bed. The object was to cleanse his stomach of mucus, to stimulate the secretory and excretory glands, and thus to eliminate all morbid material from his system. The hot water accomplished this desired effect, as shown by the elimination found in the urine, and by the rapid improvement that ensued. Besides, the hot water proved to be very grateful to his system, as it caused a warm glow and free action of the skin.

As a result of removing the cause and adopting the principles of treatment above outlined, improvement was prompt and rapid. In less than a month his asthmatic spasms had almost passed away, and, although in a climate that formerly caused intolerable distress inside of twenty-four hours, he was more uniformly comfortable than he had been for many years. Using his own words, written one month after he came under treatment, "At first I had a great deal of asthma, but it has gradually grown less, and I am now having less in New York than in the most favored locality in the mountain parks of Colorado."

In addition to the great improvement, or rather subsidence, of the asthmatic symptoms, there has been a corresponding gain in his general health. His blood has vastly improved, as shown by the decrease of morbid material and increase in the number, size, and color of the red corpuscles. His urine is much greater in quantity, is practically free from phosphates and biliary coloring matter, and has a specific gravity of about 1015. His heart is much stronger, and the sounds are again well defined. His appetite is so good that he craves nearly a pound of animal food at a meal; and, best of all, is now able to digest and assimilate such a large amount. And his nervous system has been so far restored that his memory is displaying marked improvement. All of his faculties are regaining their finer sensibilities, and he is enabled to sleep quietly and soundly during seven or eight hours every night.

BLACK OXIDE OF MANGANESE IN DYSMENORRHŒA.

BY CHARLES E. SCOTT, B.S., M.D.,
OF WICHITA, KANSAS.

I DESIRE to call attention to the use of the binoxide of manganese in those cases of dysmenorrhœa characterized by a more or less scanty menstruation, associated with pain, and which are *not* complicated with any well-definable local, inflammatory, or organic lesion to which can be traced the cause of the abnormal menstruation.

We are told by most of our best authorities that nothing can be done in the treatment of menstrual disorders by the administration of drugs, that they are of doubtful utility, and that in their stead we should resort to local treatment, tonics, and the enforcement of a strict hygiene. That there are certain conditions in which, by the proper differential diagnosis, we can, with great benefit, use certain drugs, I will try to show by calling attention to two selected cases.

CASE IV.—K. C., aged twenty-three, married; multiparous. Had always been in good health. Began menstruating at seventeen, and was regular up to two months before consulting me, at which time she had gone out while menstruating. The day was damp and disagreeable; she got her feet wet, and on returning home discovered that her menstruation had ceased. She suffered somewhat at the time, but felt well in a day or so. On the arrival of the next period she had severe dysmenorrhœa, with scanty flow. The same *rôle* of symptoms was repeated, with increasing severity, for the next two or three months, when she could stand the suffering no longer, and consulted me. I could find nothing the matter with the uterus to warrant such a state of affairs, and ordered black oxide of manganese gr. iv twice a day, half an hour after meals, for the next thirty days. Her next period arrived, and she was free from all disagreeable symptoms. I continued the black oxide for the next two months in two-grain pills, since which time (nearly a year) she has taken no medicine for this trouble, and now she menstruates regularly and is free from pain.

Case VIII. was a lady, unmarried, aged nineteen, rather anæmic. Began menstruating at fifteen; never had been "regular," and the periods were associated with much pain; so much so, in fact, that she was compelled to go to bed a day before the flow appeared and remain there until its cessation, resorting to anodyne applications and morphia hypodermatically. Her flow would occur every two or three weeks, lasting for from three to five days. Did not obtain permission for local examination, but she complained of slight leucorrhœa the day after her menstruation had ceased, also had slight ovarian tenderness over left ovary. I prescribed elix. quin., ferri et strych. three times a day, also two-grain pills of the black oxide twice daily, to be given as in the preceding case. Under this treatment her condition improved very much in the next sixty days, when I ordered the elixir to be discontinued and retained only the black oxide. The latter was continued another sixty days, when it, too, was left off, and she now (and for the past four months) is menstruating regularly, and is free from pain.

I might enumerate several other cases in which the binoxide has been used with equally gratifying results, but these two will suffice. Allow me to add, however, that during all the time that my patients have taken the binoxide they did not complain of any disagreeable symptoms arising from its administration.

Before resorting to the manganese, I had been in the habit of advising the use of the permanganate of potassium, but the unpleasant symptoms arising from its use were too constant, and I am glad to say that in the manganese dioxide we have a remedy which, in an experience of over forty cases, has failed to show any unpleasantness.

407 East Douglas Avenue.

HOSPITAL NOTES.

JEFFERSON MEDICAL COLLEGE HOSPITAL, PHILADELPHIA.

Service of J. M. Da Costa, M.D.

(Reported by E. P. Hershey, M.D., Clinical Assistant.)

GUSTATORY PARALYSIS (PERIPHERAL).

E. H., ætat. thirty-nine, domestic. Noticed, three months ago, that articles of food, save those that were pungent and affected the olfactory nerve, were tasteless. She first observed that cream had no taste; soon after, sweets. From a general survey of the patient we find that she is not anæmic, has a good color, and her bowels are regular. Her tongue is red at the edges. No blue line on the gums. Has occasional headache, but always assignable to a cause. Has a poor appetite, which she attributes to the fact that food has no taste to her. She is not hysterical.

Testing the sense of taste: with a camel's-hair brush, we paint the tip and posterior portion of the tongue with a solution of saccharin, impressing upon her mind that it is bitter; she does not perceive the sweetness. Next, upon the same portions we paint a solution of strychnia (gr. j to ℥j) with no effect. On the sides of the tongue we paint an acid—dilute acetic acid—and a saturated solution of sodium chloride, neither of which was tasted. We thus have demonstrated the entire absence of the sense of taste. This is very rare; but it is necessary for us to look further, and see if we can find a loss elsewhere. The vision is good, the eye-grounds are normal; no weeping. Hearing is good. There is no palsy of the muscles of the face. She is able to whistle, the muscles called into play being normal. There is no deviation from the median line when the tongue is protruded. Sensation, tested with the æsthesiometer, is normal, both in the track of the supra- and infra-orbital nerves, and on the tongue.

The question that arises is, What nerve or nerves are involved? The lingual branch of the fifth cranial nerve is the one that has most to do with the sense of taste; it supplies the papillæ and mucous membrane of the tongue. The glosso-pharyngeal supplies it with power of motion; this nerve goes to the back of the tongue, and supplies it with sensation. The hypo-glossus need not be considered The lingual branch of the fifth goes to the anterior two-thirds of the tongue, and the chorda tympani is joined to this lingual branch. Were the lesion in the glosso-pharyngeal, the loss of taste would be at the back of the tongue only. Were it in the lingual branch of the fifth, the anterior two-thirds of the tongue alone would be affected. Assuming that both the lingual and glosso-pharyngeal are affected, there would necessarily be impairment in motion, but this does not exist. Again, assuming that the lesion lies in the floor of the fourth ventricle, where the nerves come together, other nerves that have their origin there would show signs of change. Taste is the only part of the fifth nerve affected.

One other point to be considered is, Does the lesion lie in the cortical centre of taste? This centre is a very small spot, and should it be the origin of the disorder, unquestionably the olfactory nerve would be involved. The loss of taste is due to peripheral causes.

Treatment.—Galvanism, five cells, one electrode to the back of the neck, the other over the tongue. In order to stimulate the nerves she will be given strychnia sulph. gr. $\frac{1}{60}$ t. d. Also a stimulating mouth-wash of capsicum.

The patient, three months after treatment, had partly regained taste, her general health is good, but her food is still more or less tasteless. The case is yet under observation.

MEDICAL PROGRESS.

Saccharin for Aphthæ.—Since it has been established that saccharin possesses the properties of counteracting intestinal fermentation it has been largely used as an antiseptic remedy. Dr. Maurice Fourcier, states in the *Revue Gén. de Clin. et de Thérap.*, No. 11, that he has used it successfully in treating ten cases of aphthæ, the affected parts being painted with a saccharin solution. In eight cases the affection disappeared in from twenty-four to thirty-six hours; only in two cases did the time required for a cure extend over three days, which was due to the imperfect application of the remedy.

The following is the solution used by the author:

℞.—Saccharin . . . . . 1 part.
Alcohol . . . . . 50 parts.—M.

A coffeespoonful of this is added to a wineglassful of water and the affected parts painted with the solution five times daily. A concentrated solution should not be used, as it might prove harmful. The druggist who prepared the above solution tested the same frequently by dipping his finger first into the mixture and then into his mouth. On the evening of the same day he observed a sensation of burning in his entire buccal cavity, which on the following day was covered with an aphthous eruption; these latter lasted five days, when it disappeared without treatment.—*Wiener med. Presse*, No. 15.

Diphtheria treated Antiseptically with Quinoline.—DR. DORNAT (*Gazette hebdom.*, April 19, 1889,) recommends quinoline for the treatment of diphtheria of the mouth and throat. It can be used locally in the form of gargles or by direct applications.

As a gargle the following formula is recommended:

℞.—Quinoline . . . . . grains x.
Alcohol, 90 per cent. . . . ℥j.
Water (distilled) . . . . ℥jxss.
Essence of mint . . . . gtt. j.—M.

Direct application—the following to be applied with a camel's-hair brush (not too soft) to the surface of the pseudo-membranes:

℞.—Quinoline . . . . . grains xv.
Alcohol, 90 per cent. } . . ää ℥vjss.—M.
Water (distilled) }

Antipyrin, Diabetes, and Cataract.—The interesting communication made by DRS. GERMAIN SÉE and GLEY at the Academy of Sciences in February last on the results with antipyrin on diabetic patients, induced M. Panas to try the efficacy of antipyrin in the treatment of diabetes in connection with cataract. Two persons were treated by him: one a man aged thirty-eight, affected with bilateral cataract of two years' standing, and who was at the same time diabetic; the other was a woman of seventy-three years, of a delicate constitution, diabetic for six years, very nervous, and who presented a double cataract, that in the left eye being complete. After the administration of antipyrin in doses of 45 grains per day during one week, the sugar fell from 5 drachms to 1 drachm. It was under these conditions that M. Panas proceeded to operate for cataract, at the same time recommending the patient to continue to take 30 grains of antipyrin per day. From these cases M. Panas concluded: 1. That antipyrin possessed an antiglycogenic action both prompt and efficacious. 2. That it has succeeded in those cases in which neither the diet nor the drugs employed had succeeded in reducing the proportion of the glucose below a given quantity. 3. That for it to be efficacious it is necessary that the daily dose at first should consist of 45 grains. 4. That the effect became evident even when the patients were allowed to continue a moderate proportion of farinaceous substances. Dr. Albert Robin, well known for his researches in connection with antipyrin and other drugs of that class, said that he did not believe that one could distinctly say that antipyrin did not suit such or such diabetic patients, but when the treatment is commenced, the appearance of certain symptoms should be an indication to suspend the remedy without delay. He then named the indications and contra-indications of antipyrin in the treatment of this affection. In conclusion, he said that antipyrin can render the greatest service to a very large number of diabetic subjects, and it is destined to take an important place in their treatment; but, like all active drugs, it is a two-edged weapon, which one ought to know how to handle with ability, and which it would be imprudent to employ indiscriminately in all cases.—*Lancet*, April 20, 1889.

Hyoscin.—DR. OTTO DOMBLUTH (*Berliner klin. Wochenschr.*, No. 49, December 3, 1888) reports the results of the use of hyoscin in the treatment of the insane in the asylum at Brieg, in the district of Breslau. He employed usually, and exclusively in his later practice, the hydrochlorate, giving it by subcutaneous injection in doses ranging from 0.2 to 1.5 mgs. (or from about $\frac{1}{500}$ grain to $\frac{1}{60}$ gr.) and administered by the mouth in doses of $\frac{1}{120}$ to $\frac{1}{32}$ of a grain. He found the former method in every way the most effective, and he gives a table showing the comparative effects of different doses administered in both ways, in various forms of insanity. For example, in sixteen cases of epileptic insanity, out of fifty-nine injections of hyoscin in quantities varying from $\frac{1}{500}$ to $\frac{1}{125}$ grain, only four were ineffective, and in fifty-one complete quieting of the patient for twelve hours or more was obtained, while with doses of from $\frac{1}{64}$ to $\frac{1}{32}$ grain given by the mouth over 25 per cent. were failures. The inconvenient symptoms of temporary paralysis, disturbance of accommodation, etc., were also more pronounced after hypodermatic doses, but in no case were sequelæ observed that called for special caution in any one direction. The appetite was never disordered, and he did not find any increased tolerance of the drug requiring increasing doses, even after it had been used a hundred times or more. Contrary to the experience of Kuhlwetter (*Irrenfreund*, 1887, No. 7), the author found that in his cases the injections were not especially painful.

Dr. Dombluth found that distinctive tendencies were only diminished by the drug in the acutely agitated patients, but that untidy habits were usually benefited by it. In closing his paper he shows that, owing to the smallness of the dose required, its employment is not at all counterindicated by its high price.—*American Journal of Insanity*, April, 1889.

Naphthol and its Administration.—This drug can be administered in the form of lotions, mouth-washes, injections, liniments, and antiseptic as well as disinfectant lotions. Camphor and alcohol are the best vehicles for its administration.

1. *Lotions.* The following formula is the best:

℞.—Naphthol β . . . . 1 part.
Alcohol 60° . . . 1000 parts.—M.

To be applied to regions covered with hair which one desires to render aseptic.

Or:

℞.—Naphthol β . . 10 to 15 parts.
Alcohol 60° . . . 1000 " —M.

This forms a stronger solution, and is used to render aseptic denuded cutaneous surfaces.

2. *Injections.* This solution is to be prepared by heat and to be kept at a medium temperature. Before using

it the syringe should be warmed. The following is the formula:

℞.—Naphthol β . . . . 10 parts.
Alcohol 90° . . . . 80 "
Water (distilled) . . . 120 " —M.

3. *Mouth-washes.* For toilet purposes a few drops of the following should be added to a glass of water:

℞.—Eau de Botot . . . . 600 parts.
Naphthol β . . . . 1 part.—M.

4. *Liniments.* For this purpose camphorated naphthol is used; this is obtained by triturating the following until a liquid is obtained:

℞.—Powdered camphor . . 2 parts.
Powdered naphthol β . . 1 part.—M.
—*Gazette hebdomadaire*, April 19, 1889.

Milkmaid's Cramp.—DR. REMAK was recently enabled to bring a case of true milkmaid's cramp before the Medical Society of Berlin. This malady was originally described and classified by Basedow. It is a form of muscular incoördination analogous to that of writers, ironers, and cigarette-makers, and involves principally the median and superficial nerves. In Dr. Remak's case both hands were affected with spasmodic contractions on attempting any kind of movement, but particularly that of prehension. The patient had for some weeks been obliged to milk uninterruptedly for several hours daily, and is now quite incapacitated from following her occupation. As a general rule, the symptoms take a much longer time to develop.—*Medical Press*, Feb. 20, 1889.

Œdema as a Diagnostic Sign in Carcinoma of the Stomach.—DR. C. BAERT, of Brussels, writing in *La Clinique* on cancer of the stomach, calls attention to the frequency with which œdema of the ankles is met with in this affection after it has lasted a few months—a diagnostic aid which is by no means new, but is, he thinks, in danger of being too much overlooked at the present day. He gives a number of cases recently occurring in the various hospitals in Brussels in which œdema was present. In one of these cases the œdema came on as early as three months after the first symptoms of the affection made their appearance; in two other cases it was noticed after four months; but in most of the other instances it was delayed till the lapse of from six months to a year after the onset. In one case, where there was no evident cause to which to attribute the loss of appetite and the wasting complained of by the patient, Professor Carpentier, noticing some œdema of the ankle, diagnosed carcinoma of the stomach, and found his diagnosis confirmed by the appearance a month afterward of all the usual signs of the affection. Several of the cases presented a marked increase in the nitrogen excreted in the urine. With regard to the deficiency or absence of hydrochloric acid in the stomach in cancer of that organ, M. Baert admits that it is usual, but agrees with Wolff and Ewald in saying that this sign is by no means peculiar to cancer, as it is found in other gastric affections.—*Lancet*, April 13, 1889.

The Treatment of Sciatica by Local Freezing of the Skin.—This mode of treatment has been recommended by Dr. Debore, who sprayed the affected surface with methyl-chloride. This drug as well as Dr. Debore's apparatus being somewhat difficult to obtain, DR. MILOTTI has proposed the use of sulphuric ether applied with a Richardson spray; the results were very satisfactory.

Professor Ughetti, of Catania, succeeded in curing six or seven cases of sciatica by this method. Dr. G. Alonzo reports in the *Riforma medica*, No. 53, the case of a thirty-two-year-old woman, a sufferer from severe sciatica, who, after receiving three applications of the ether spray, felt much improved and was enabled for the first time in many months to obtain a refreshing sleep. After the further application of six sprayings she was well able to walk about—in fact, was entirely cured. The duration of each application was from twelve to fifteen minutes, the quantity of ether necessary for each séance amounting to something like six and a half ounces. Dr. Alonzo regards the application of this remedy as of great therapeutic value, and thinks it should not be omitted in a single obstinate case.—*Wiener med. Presse*, March 24, 1889.

The Disinfecting Action of Steam.—According to some new researches made by VON ESMARCH on the action of steam as a disinfectant, it would appear that the effects in relation to the destruction of bacteria depend not so much upon the temperature as upon the degree of saturation of the steam. If there is air with it, the power of destroying organic germs is very much diminished. Thus, in experimenting on the spores of malignant pustule, von Esmarch found that, while superheated steam which was not in a condition of saturation at a temperature of 248° F. was unable to destroy the spores in half an hour, saturated steam at 212° F. destroyed them in from five to ten minutes.—*Lancet*, April 13, 1889.

Picric Acid in the Treatment of Erysipelas.—DR. CALVELLI (*Revue Gén. de Clin. et de Thérap.*, March 28, 1889) writes that he treats erysipelas by painting the diseased surface five or six times daily with the following solution:

℞.—Picric acid . . . . 23 grains.
Water . . . . . ℥viij.—M.

Combining with this internal injections of quinine he obtains diminution of the swelling and pain in from twelve to twenty-four hours.

Antiseptic Sutures.—It would appear that there is a growing tendency amongst surgeons to restrict the use of catgut as a suture material, and revert, where practicable, to the more easily disinfected silk threads. The observations of Kocher (*Correspondenzblatt für schweizer Aerzte*, 1888) upon this subject cannot fail to prove of interest to the thoughtful surgeon. This distinguished observer has for a long time past tried experiments with a view to perfect the sterilization of animal tissues used for the purpose of sutures and ligatures—the fluid hitherto recommended by him for keeping the gut in being the essential oil of juniper—sutures prepared in this way being very nice and soft to handle, and in the majority of cases aseptic; but a series of cases in which the wounds did not follow an aseptic course suggested from their similarity a common source of infection, and a thorough revision of materials employed narrowed the

question down to the catgut used at the clinic for sutures and ligatures. A comparison being made with this catgut and sterilized silk showed that it was the former that was at fault. Kocher states that he has long been impressed with the difficulties in the way of rendering aseptic catgut and similar animal substances, as the fat in the interstices of the tissue prevents the thorough saturation by antiseptic fluids, and the tissue is unsuitable for the best of all sterilizing agents—viz., heat.

The well-known case of Volkmann, in which catgut which had been kept for months in a twenty per cent. solution of carbolic acid infected a patient with true anthrax, is perhaps the most significant observation in connection with this subject, and serves to accentuate the fact that a perfectly reliable animal absorbable ligature is yet to be found.—*Dublin Journal of Medical Science*, April 1889.

The Local Treatment of Diphtheria by Salicylic Acid.—The treatment advocated by D'ESPINE (*Revue Méd. de la Suisse Romande*, Jan. 20, 1889) has its *raison d'être* in the discovery by Löffler of the existence of a pathogenic bacillus in diphtheria, which, coming from outside the body, implants itself on the mucous surfaces and leads to the production of the characteristic membrane. The important point regarding the bacillus is, that the symptoms met with in diphtheria—prostration, low temperature, feeble circulation, hemorrhage, and albuminuria, are not due to the entrance of the bacillus into the circulation, but to the absorption of septic products which are formed at the points affected. An accompanying febrile condition is probably due to the passage into the circulation of streptococci, which are usually found in the false membrane along with the bacillus. D'Espine's researches support Löffler's views. He asserts that diphtheria is at first a local infection; that the false membrane is a sign of this, and not of an infection of the blood by microbes; and that the general symptoms are due to a septic intoxication of the blood, the septic products being formed and absorbed at the seat of the false membrane.

With E. de Marignac he has investigated the germicidal action of various drugs used in the treatment of diphtheria. Benzoate of soda (5–10 per cent.), chlorate of potash (5 per cent.), boracic acid (4 per cent.), sulphide of sodium (2½ and 5 per cent.) placed in contact with the bacillus for five minutes, did not arrest its growth; but corrosive sublimate (1 in 8000), carbolic acid (1 in 50), salicylic acid (1 in 2000), chloral (1 in 100), permanganate of potash (1 in 2000) gave a positive result. Of these the author prefers salicylic acid (1.5 or 2 per 1000), which in this dilution may be used freely. Some of the other germicides are not suitable except when used with a brush, on account of risk from absorption. The main points in d'Espine's paper may be summarized as follows:

(1) The diagnosis should be made early. This may usually be accomplished by examining microscopically a piece of the false membrane, and then by staining and finding the bacillus, which is slightly concentric in shape and about the same length as the tubercle bacillus, but two or three times as broad. After a time, the bacilli are difficult to find in the pultaceous mass, but then the appearance of the membrane itself is characteristic.

(2) Local treatment should precede and accompany general treatment, and the earlier it is used, the better is the chance of preventing the absorption of the toxic products of the bacillus. All the diphtheritic surfaces must be reached by the solution used. The mouth should be irrigated or syringed out with a solution of salicylic acid (1.5 or 2 per 1000) every hour or two hours, according to the symptoms, or the patient may gargle when possible, and several tablespoonfuls are to be poured into each nostril. Two or three pints of the solution may be used in twenty-four hours; but in the case of a child, where a large quantity may be swallowed, it is well to reduce the strength to 1 in 1000 or 1500. When, however, the false membrane is widely spread and thick, this treatment will not suffice. The patches must then be painted with something which will soften and disintegrate the membrane, and for this purpose citron juice, chloral and glycerine (1 in 5), corrosive sublimate (1 in 2000), carbolic acid (1 in 50), or papaine or papyotine may be used. Rough manipulation must be avoided, otherwise the irritation will increase the fibrinous exudation, and increased absorption will occur.

(3) Debilitating drugs should not be given; prostration must be treated by food, stimulants, and iron.

The results obtained from this treatment by d'Espine have been very satisfactory.

Salicylic acid may also be used as a prophylactic when diphtheria is prevalent, and in scarlatinal angina. In cases of tracheotomy in diphtheria, five or ten drops of a solution (1.5 in 1000) may be dropped into the canula every ten or fifteen minutes.

The author disclaims all idea of originality, except as regards method of irrigation. He quotes a number of opinions, both favorable and unfavorable, as to the efficacy of salicylic acid.

It is interesting to notice that some years before Löffler's discovery of the bacillus, a mode of treatment of diphtheria and scarlet fever on the same lines as that advocated by M. d'Espine in this paper, was recommended by Dr. Pownall, of Chorlton-cum-Hardy, in a letter to the *Lancet*. His formula was:

℞.—Salicylic acid	1–2 dr.
Gum tragacanth	1 oz.
Syrup	½ oz.
Tincture of orange . . .	½ oz.
Water	to 6 oz.—M.

A tablespoonful every two hours, alternately with iron, if necessary.

The drug being in suspension, has a local as well as a constitutional effect.

Iodine Applications in Erysipelas.—DR. TICHOMIROW, writing in a Russian military medical journal, recommends the employment of tincture of iodine as an external application in erysipelas, even in cases where bullæ have formed. He paints the iodine over the affected part and its vicinity three or four times a day. The irritation caused by the treatment is easily allayed by the application of a little camphorated oil. Usually he found a couple of days sufficient to reduce the infiltration and to bring the temperature down to normal. A similar mode of treatment he also considers very beneficial in cases of boils and carbuncle. Even after these have broken, he recommends that the iodine should still be applied, the wound being cleansed from pus and a dressing of cotton-wood applied.—*Lancet*, April 6, 1889.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE . . . . . $5.00.

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

SATURDAY, MAY 11, 1889.

THE VALUE OF BINIODIDE OF MERCURY AS AN ANTISEPTIC.

THE conclusion reached by Koch, in his article on disinfection and antiseptics in the *Mittheilungen aus dem k. Gesundheitsamte*, vol. i., 1881, p. 264, that a single application of a very dilute solution, 1–1000 to 1–5000, of mercuric bichloride is sufficient to destroy the most resistant organism in a few minutes, and that a solution of 1–20,000 is sufficient, if the contact be prolonged, has given this substance a world-wide use in all branches of medicine, particularly because surgeons have practically found Koch's experimental deductions to be true.

Until recently, however, very few practitioners have recognized the fact, to which this same investigator called attention, and which has been particularly brought forward by his pupil Laplace in the *Berliner klinische Wochenschrift* for October, 1887; namely, that in the presence of albuminous substances an albuminate is formed with the mercury which renders the dressing useless, save in that it does not form a fruitful spot in which germs may multiply.

Klein (*Fifteenth Annual Report of Local Government Board*, 1886, p. 155) goes even further than this, and asserts that distilled water should always be the solvent used in making this preparation, since the salt may otherwise unite with proteids or other substances and become useless.

Although we are now accustomed to use tartaric acid in our antiseptic fluids in order to avoid such accidents, the danger of the formation of albuminates nevertheless exists to a considerable extent, sufficiently, at least, to warrant the use of other preparations of mercury, even if their antiseptic power be somewhat less than the bichloride, and if they do not bear similar relations to the albumins.

For some time past the biniodide of mercury has been thought of and been tried in this country and abroad. Recently, in a communication in the *Proceedings of the Royal Society of Edinburgh*, vol. xv. p. 235, DR. G. SIMS WOODHEAD has given the results of a series of experiments carried out with the red iodide of mercury, using as control tests the bichloride in solutions of the same strength as the more recently employed salt. The first part of his research was devoted to the determination of the action of albumins on these salts, ox blood being employed. The results reached indicate that Laplace and Koch are entirely correct in their statements, and that corrosive sublimate may be rendered useless in the presence of albumin, an insoluble precipitate of the albuminate of mercury being formed. On the other hand, the biniodide is entirely free from these disadvantages, albuminous solutions of this salt remaining clear for days. The solution is to be made by dissolving fifteen and a half grains of the salt with a slight excess of iodide of potash in thirty-four ounces of distilled water. Such a solution is stable, but is not one, in reality, of biniodide of mercury, but of the double iodide of potash and mercury.

Turning from this question to the effect upon germs, Woodhead placed the bichloride solution and blood in a dish exposed to the air, and also exposed in a similar manner and in a corresponding place the biniodide solution and blood. As a control experiment a third jar holding the same quantity of blood and distilled water was put alongside the others. At the end of six weeks there were a few micrococci and bacilli in the bichloride solution, its surface was covered by a luxuriant growth of *penicilium glaucum*, but there was no odor on stirring the liquid.

In direct opposition to this was the state of the biniodide solution, which was absolutely free from any change. In the control jar, of water and blood, the odor was exceedingly bad and the fluid swarmed with microörganisms.

By the addition of tartaric acid or common salt to a bichloride solution we increase its absorbability into the body and increase the danger of a systemic

effect. Here again, however, the biniodide excels the bichloride, for, as has been pointed out by CASH, in the *Local Government Board Report* (supplement), 1885, p. 186, guinea-pigs are much more tolerant of it than of the bichloride, while most pharmacologists agree that the lethal dose of the biniodide is nearly twice as great as of the bichloride. It is, however, worthy of note that should the former be taken in toxic dose none of the antidotes to the latter would be effective.

From these studies, therefore, we are in a position to make thorough trials of the biniodide as an antiseptic and to replace the bichloride with it if it prove practically useful.

Very recently DR. BERNARDY has used it in this city with very good results, and further trials will certainly be made. Woodhead has found, too, that such a solution is very useful in the preservation of specimens.

RESULTS OF FOOD AND DRUG INSPECTION IN NEW JERSEY.

THE salutary effects of the rigid enforcement of the laws of New Jersey for the prevention of the adulteration of food and drugs are shown by the Report of the Dairy Commissioner of the State for 1888. The amount of oleomargarine sold during the year has been very small, and the transactions in this article have been carried on strictly in accordance with the legal provisions. Milk inspection has covered all parts of the State, and the result shows the milk supply to be in excellent condition. Cases of adulteration of this article have steadily diminished, until in this year they have been fewer than ever before.

The examination of various foods and drugs has only recently been instituted, and consequently the deterring influence of warnings and prosecutions has scarcely had sufficient time to work a change in practices long in vogue. Of the numerous articles of food analyzed during the year, over forty-eight per cent. were found to be adulterated. It is true that the adulterants used are rarely injurious to health, but they are fraudulent, and the purchaser of sophisticated articles is not only deceived but he is robbed of a portion of his purchase money. The substitution of adulterated medicinal drugs for pure articles is a heinous offence, as it may place life in peril, and it should therefore be punished with extreme severity.

The people of New Jersey are to be congratulated upon the possession of laws against food adulteration and the efficient manner in which they are administered under the superintendence of Dr. Newton. In the absence of legislation on this important subject, Pennsylvania presents a striking contrast to her sister State. The legislature has recently ignored a plea for milk inspection for a populous section of the State and has also defeated a praiseworthy attempt to secure legislation against food adulteration throughout the Commonwealth. Comment is unnecessary.

THE Johns Hopkins Hospital, of Baltimore, was formally opened by the Governor of Maryland last Tuesday, in the presence of a brilliant audience, and this act marks an epoch in the history of medicine in this country. The munificent endowment of over three millions of dollars which the philanthropy of Johns Hopkins placed in the hands of his trustees; and their intelligent and careful management by which they have constructed and equipped this house of mercy without taking a dollar from the principal placed at their disposal, but actually increasing it by $113,000, have resulted in giving to the city of Baltimore a hospital which, in the excellence of its construction, perfection of its arrangement, and completeness of its appointments is without an equal on this continent, and probably in the world.

A full description of the seventeen separate buildings was given in THE MEDICAL NEWS of last week, and to-day we have the pleasure of laying before our readers the admirable address of Dr. Billings delivered at the formal opening. Dr. Billings is well qualified to speak of the hospital and its aims, for, from its very beginning, more than thirteen years ago, he has been the confidential adviser of the Trustees in the planning and construction of the hospital and in its organization.

The broad intelligence which has planned this hospital, its liberal endowment, and the character of work which it stands ready to perform, are sure to render it a potent factor in the advancement of medical science and of medical education in this country.

THE volume of *Transactions of the Congress of American Physicians and Surgeons*, held at Washington last autumn, has just been issued. It forms a very handsome octavo volume of 386 pages, and its publication has been ably supervised by the Secretary of the Congress, Dr. W. H. Carmalt, of New Haven. The volume contains the elaborate and able

papers on the "Diagnosis and Treatment, Medical and Surgical, of Intestinal Obstruction," by Drs. Fitz and Senn, with the discussion elicited, and on "Brain Localization and Surgery," by Drs. Mills and Park, and the discussion following by Drs. Starr, Ferrier, Horsley, Keen, and Weir. The concluding paper is the address of the President, Dr. Billings, on "Medical Museums." The volume constitutes a notable addition to our literature and is a fitting memorial of the meeting it records.

THE American Association of Genito-urinary Surgeons will hold their next annual meeting at Newport on May 21st, 22d, and 23d.

THE Twenty-second Annual Meeting of the Canadian Medical Association will be held at Banff, N. W. T., on the 12th, 13th, and 14th of August next, under the Presidency of Dr. George Ross, of Montreal.

The Canadian Pacific Railway Company has agreed to carry members and delegates and members of their families at the following rates: From points in Ontario and Quebec, to Banff and return at $95 each, including a double berth in sleeping car for each person, and meals in the dining cars on the way west from Montreal or Toronto and back, and four days' living at the Banff Hotel. The passage tickets will be made good from and to any points on the Canadian Pacific Railway, in either Ontario or Quebec, to Montreal or Toronto, but berths and meals will begin at these two places only.

Owing to the provisions of the Interstate Commerce Law, it will be impossible to get reduced rates from points in the United States, with the exception of St. Paul, Minn., from which the following rate is offered: $60 to Banff and return, including meals and sleeping car accommodation *between Winnipeg and Banff only*. Delegates from the United States are therefore requested to make their own arrangements between their homes and points on the Canadian Pacific Railway.

It is intended that the party shall leave Montreal on the evening of the 6th of August, by the regular Pacific express and arrive in Winnipeg on the 9th, and stop over one day there: leaving Winnipeg on the 10th of August, they will arrive at Banff early on the morning of Monday, August 12th. The meeting of the Association will then be held in the hotel on the 12th, 13th and 14th, after which the members of the party can either return at their convenience or take a trip to the coast, leaving early the following morning (August 16th), for which special terms have been arranged as follows: From Banff to Victoria and return, not including meals or berths, $20, or $30 including meals in the dining car and berths. The tickets for this excursion will be on sale at Banff to members and delegates and their families only.

The special tickets issued by the Canadian Pacific Railway to Banff and return will be good for sixty days, and the holders will be allowed stop-over privileges on the Canadian Pacific line at pleasure.

In addition to the members of the Canadian Medical Association a cordial invitation is extended to all members of the regular profession in good standing in the Dominion of Canada, the United States, and Great Britain, to whom the necessary certificates will be sent on application to Dr. James Bell, General Secretary, 53 Union Avenue, Montreal.

DR. HARRISON ALLEN, of Philadelphia, will deliver the next Toner lecture at the National Museum in Washington on the evening of the 29th of this month. His subject will be "The Clinical Study of the Skull, especially undertaken in Connection with the Morbid Conditions of the Jaws and Nasal Chambers."

A VINDICATION of the report made some five years ago of a Committee of the New York Academy of Medicine in the matter of the Paris diploma of Dr. Fordyce Barker has just come, in a most singular way, from the Sandwich Islands. Dr. Prince A. Morrow, in a letter to the *Medical Record* (April 28th), states that at Honolulu he met a Dr. George H. Trousseau, a son of the famous Paris physician, who, in narrating some reminiscences of his Paris life, mentioned having met at his father's dinner table Dr. Fordyce Barker, and he distinctly recalled his father mentioning there the fact that the Faculté de Médecine had conferred its diploma upon Dr. Barker. He also stated that he saw the diploma and, at his father's request, he personally carried it to Dr. Barker's hotel and left it there for him.

Dr. Trousseau said that it "was a matter of regret to him that he had not heard of the charge against Dr. Barker until many months after it was brought before the Academy, and thus had not the opportunity to refute it, which he would gladly have done."

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 2, 1889.

THE PRESIDENT, ALFRED L. LOOMIS, M.D., IN THE CHAIR.

DR. W. B. JAMES read a paper on

THE RELATION OF THE TUBERCLE BACILLUS TO ITS ETIOLOGY.

Having stated that the unity and specific nature of pulmonary tuberculosis had been established before the discovery of the tubercle bacillus in 1882, he proceeded to give a *résumé* of the conclusions Koch arrived at from his researches. In the seven years which had elapsed since this discovery, he went on to say, an enormous number of investigations had been carried on, and their results had been to confirm completely and establish the correctness of Koch's conclusions. It was also fairly well established now that the tuberculous process is capable of setting up inflammation in adjacent tissues which may be either acute or chronic.

By pulmonary phthisis he understood a tuberculous inflammation of the lungs, and he considered, therefore, any secondary and contributing cause or causes as unnecessary. Clinical experience taught that different individuals respond very differently to tuberculosis infection, and also that the same individual responds differently to it at different times. In this connection he referred to Trudeau's experiments with animals inoculated with tuberculous virus and exposed to different forms of environment, the results being very different in those closely confined in quarters with bad hygienic conditions, from the results in those allowed free exercise in the open air. In the dead-house of the New York Hospital he had been struck with the large number of individuals whose lungs presented lesions which showed that they had at one time been the subjects of phthisis and had recovered from it.

Whether or not any previous lesion of the lungs was necessary for the development of tuberculosis he did not think was established. The sum of clinical experience seemed to indicate that tuberculosis develops more readily when there has been such a previous lesion, but that in many cases there is no previous lesion whatever. The conditions on which tuberculous infection in any given instance seemed to depend are, *first*, the number of the germs, and, *second*, the condition of the microbes as regards vitality. Other things being equal, therefore, the greater the number of bacilli and the greater the activity of the virus, the stronger would be the chance of infection.

Another point of interest was in regard to the channel of infection. Our knowledge of the lymphatic system of the lungs was, unfortunately, very limited, and the question whether the infection was contracted by inhalation or in other ways, he felt compelled to leave untouched. To sum up, he said, the only factor necessary for the production of pulmonary phthisis is the bacillus tuberculosis or its spores.

DR. J. WEST ROOSEVELT read a paper on

THE RELATION OF THE TUBERCLE BACILLUS TO THE EARLY DIAGNOSIS AND PROGNOSIS OF PHTHISIS.

(See page 510.)

DR. JAMES TYSON, of Philadelphia, who had been invited to participate in the discussion, said that he was in entire agreement with his predecessor in the discussion, and remarked that it is now so generally conceded that the bacillus of tuberculosis is the essential cause of that disease, and especially of pulmonary consumption, that for some reasons it seemed scarcely worth while to repeat the argument therefor. It is, however, always important not to lose sight of the ground of adoption of any truth, and especially is this the case with truths in medica science; and the more so, of course, when the conditions are difficult to establish. It is further important to keep reasons fresh in memory, lest we grow to accept views too readily, for it is better to be brought up in a school of scepticism than in a school of credulity, although perhaps neither is desirable.

The conditions on which are based the belief that the bacillus is the cause of tuberculosis are exceedingly difficult to establish. So difficult, indeed, did they seem to him that for a long time he could not regard them as possible. He believed now, however, that they had been placed on a firm basis. The conditions referred to, which were doubtless familiar to most of those present, were those which are generally regarded as essential to establish that any vegetable organism is the cause of a given infectious disease. They are as follows:

1. The organism must be found in the blood or tissues of the infected animal, or in both.

2. It must be obtained from the blood or tissues in a state of absolute purity.

3. The organism, thus pure, must be capable of producing the same disease when introduced into the blood or tissues of an animal susceptible of it.

4. The same organism must be found in the blood or tissues of the second animal in which the disease has been produced.

These conditions, as he had said, he believed to be now fully established in the case of the bacillus tuberculosis. The second of these, the steps to the securing of which are by far the most difficult to carry out, has been secured by the culture processes now brought to a state of such high perfection. Without going into further detail, he would simply say that the methods followed by Koch in relation to tuberculosis were beyond criticism, and, he thought, were now generally allowed.

But it is plain also, he went on to say, that the establishment of the proposition that tuberculosis is thus caused does not preclude its being caused also in some other way, and in consequence of this, for a time, a halt was necessitated in proclaiming that the bacillus is the sole cause of tuberculosis. Very soon after the publication, in 1866, of Villemin's experiments in the inoculation of tuberculosis it was announced that the disease could be produced by the inoculation of indifferent substances (that is, simple non-specific irritants), and among the supporters of this proposition who based such views on their own experiments were Wilson Fox (1868), Cohnheim, Waldenburg, and Burdon Sanderson. Cohnheim was the first to retract, as the result of further experiments, even before 1882, when Koch's observations were published. Wilson Fox's experiments were repeated at his request in 1883 by Dawson Williams with entirely negative results, which led to a renunciation of his former views by Fox, in December of that year. Finally, Sternberg's experiments (reported in the

American Journal of the Medical Sciences, January, 1885), consisting of the injection of ultramarine blue and powdered glass into the peritoneal cavities of rabbits, seems to have settled the question, and even Formad, who was one of the last to yield, admits that the products are non-specific inflammatory nodules. Thus, the last obstacle to the doctrine that the bacillus is the sole cause of tuberculosis is removed, and attention can now be directed most profitably to the corollaries which grow out of it.

The first inevitable deduction is that tuberculosis must also be contagious; and yet the contagiousness is by general acknowledgment so slight (so few cases being directly traceable to contagion as a cause), that some explanation is necessary. The explanation, he thought, would be found in the mode of dissemination of the contagion, as shown in some comparatively recent observations by Cornet, who inoculated animals with sponge scrapings from the walls of rooms occupied by phthisical patients. Large numbers of animals thus inoculated were found tuberculous, while the control experiments, made with sponge scrapings from houses not inhabitated by tuberculous patients, gave negative results. Further, in no case was the dust of the walls infectious where sputum cups were exclusively used to receive the expectorated matter, although such sputum abounded in bacilli. Thus it is learned that it is through the dried sputum whose bacilli-containing particles are disseminated in the air that the disease is spread, as was indeed originally suggested by Koch; infection being chiefly through the respiratory organs.

Tuberculosis may be characterized as feebly or slightly contagious in the same way and for the same reason that typhoid fever is slightly contagious, because ordinarily the excreta are promptly removed, even if not disinfected. It is only when they dry upon the linen, and thence become scattered through the air, that they enter the lungs or alimentary canal and communicate the disease, as sometimes happens, as is well known, to those nursing typhoid cases. The same conditions, also, which intensify the contagion of diseases acknowledged to be contagious increase the activity of that of phthisis. Thus, the disease is most frequent when people are crowded together, as in prisons, where the mortality is four times as great as outside, and in manufactories, where it is twice as great. To this may be added the fact that married couples infect each other, especially the husband the wife, and that the members of healthy families may become infected, one after another, after removal to a house previously occupied by a tuberculous patient. To the same end tend the environment experiments of Trudeau already referred to to-night.

In the same direction pointed some most valuable and laborious observations of Dr. Lawrence L. Flick, of Philadelphia, illustrated by a series of maps locating the deaths from tuberculosis in a single city-ward for twenty-five years, in which he shows that of the infected houses, scarcely 10 per cent. are isolated (that is, have not an infected house next to them). About 33 per cent. of the infected houses, moreover, have had more than one case in them. Finally, through diagrams showing the distribution of smallpox, typhoid fever, diphtheria, and scarlet fever, he shows that the groupings of phthisis are identical with those of these contagious diseases.

That tuberculosis is also communicated through the alimentary canal is likewise well attested. The chief medium, of course, is food, and especially milk. Gerlach first fed young animals upon the milk of tuberculous cows, with results sufficiently successful to justify the conclusion that there was some specific virus in the milk of such cows which would produce tuberculosis of the alimentary canal or mesenteric glands. Albert reported the case of a litter of young pigs fed on the rejected milk of a tuberculous cow, all of which died of tuberculosis. Finally, Bang reported at the meeting of the International Medical Congress at Copenhagen, in 1884, that he had demonstrated tubercle bacilli in the milk of cows suffering from tubercular mammitis and the production of tuberculosis by the inoculation and ingestion of such milk. Nocard also showed the presence of tubercle bacilli in the milk of cows. Sims Woodhead, in an examination of over six hundred cows in the Edinburgh dairies, found thirty-seven in which there was mammitis, but in the milk of only six, or sixteen per cent. of cases, could he demonstrate tubercle bacilli, and these in small numbers. In one of the six, and subsequently in five others, they discovered bacilli in enormous numbers in the udders.

Such observations as these are admirably supplemented by those of Cornet, reported to the Paris Congress for the Study of Tuberculosis in 1888, when he showed that cultures of the tubercle bacillus introduced into the intestines penetrate very quickly into the mucous walls. At the end of four days after introducing into the œsophagus of guinea-pigs a few drops of tuberculous cultures, he noted submucous tubercular lesions and rapid generalization, but without epithelial lesions, while bacilli were found in the mesenteric glands. But while the general expression of the Congress was against the use of tubercular flesh, and especially tubercular milk, and while the dangers of the use of the former were emphasized, no absolute demonstration of the harmful effects of meat from tuberculous cattle seems to have been afforded; while there were those, as Nocard, who thought its dangers might be exaggerated. Cagny, however, related a case of tuberculosis transmitted from man to poultry. The chickens belonging to a certain family, one member of which was the subject of pulmonary consumption, were found to be almost all diseased. Inquiry discovered the fact that the sick man had been in the habit of walking in the garden, where the chickens had eagerly seized upon the matter expectorated by him. The liver was found to be the seat of the tuberculosis in the chickens.

Again, Mosler, of Greifswold, reports the case of a patient who could not be persuaded to eject his sputum, but swallowed it in large quantities. Ten days after his first attack of cough, diarrhœa with colic set in, which continued until death supervened ten days later. The autopsy revealed tuberculosis of the lungs and intestine, but nowhere else in the body. Mosler is therefore inclined to refer tuberculosis of the intestine to swallowed sputum, rather than to general infection; although he failed to produce intestinal tuberculosis by feeding animals with tuberculous sputum and lung tubercle.

Having referred to the invasion of the skin by tuberculosis, and to inoculation with it by means of circumcision, etc., Dr. Tyson said that the possible transmission of tuberculosis by flies is another important fact of prac-

tical significance. In the last year E. H. Hoffman, of Dresden, has reported that some flies taken from the room of a patient in whose sputum were large numbers of bacilli, were found on examination to have tubercle bacilli in their intestines; while some fly-specks on the walls of the house also contained bacilli. Again, he fed some apparently healthy flies upon tuberculous sputum, and in a few days a large number died. Finally, in order to determine the vitality of these bacilli he inoculated them into the anterior chamber of the eyes of guinea-pigs in five instances. In four there was no result, but in the fifth success was complete; a large number of fresh, small, tuberculous nodules being found afterward in the lungs, liver, and spleen.

The relation of the bacillus to heredity has as yet failed of a satisfactory explanation; more particularly the congenital tuberculosis, for the acquired is probably the result of inoculation by the all-pervading bacillus of tissues well prepared to grow it. Congenital tuberculosis admits of two solutions: first, that the bacillus exists in the ovum of the mother or is communicated to it with the seminal fluid; and, second, that it is passed from the blood of the mother to that of the fœtus through the placenta. In support of the first is the fact that Johne has demonstrated the bacillus in the spermatic tubules and beneath the epithelium of the prostate. Against it is the fact that Rohlfs inoculated rabbits with serum from consumptives with uniformly negative results. Beyond this all is speculation. The second explanation has, however, more tangible support; first, in that other bacteria have been shown to be thus transmitted, as the spirillum of relapsing fever, by Spitz, and the bacillus of typhoid fever by Neuhaus. Such transfer, however, presupposes, of course, the presence of bacilli in the blood, and while Weichselbaum has succeeded in demonstrating tubercle bacilli in the blood, it is very infrequent.

It must be admitted, too, that although Landouzy and Martin have obtained positive results of the inoculation of animals with the placentas of phthisical patients, no tubercle bacilli were found in the products, which may therefore have been pseudo-tuberculosis. Chanen relates the case of a tuberculous mother prematurely confined at seven and a half months, whose child died three days later with tubercular lesions of the liver, spleen, and mesenteric glands. Merkel reports the case of a woman tubercular at conception, who was delivered at time of a child which died. At the autopsy caseous nodules were found in the palatine arch, in the lymphatic glands, and behind the hip-joint. In neither of these cases, however, was the bacillus sought for. Landouzy and Martin have produced tubercular products by inoculating portions of organs from apparently healthy fœtuses derived from tubercular mothers, but the tubercle bacillus was again wanting in the products; while Leyden has repeated their experiments with negative results. Johne, however, has demonstrated tuberculosis in the fœtus of a tuberculous cow. Since most of the blood of the umbilical vein passes through the liver, this organ should be a favored seat of congenital tuberculosis of placental origin, as was the fact in Johne's and in Chanen's case.

Another important corollary to the proposition that the tubercle bacillus is the essential cause of tubercular disease relates to the tenacity of the life of the bacillus. Caden and Mollet, in experiments made with a view to ascertain this, found that tubercular matter, dried and pulverized, is capable of transmitting tuberculosis 102 days after such preparation; but they conclude that virulence does not persist after from 30 to 70 days, unless special care is taken to preserve it. In bulk, as in dried lung, they found virulence maintained 150 days. Schule and Fisher claimed that tuberculous matter remains active at least six months, while Pietro asserts that well-dried sputa may retain infectious properties for nine or ten months at a mean temperature of 77° F.

The evident practical deductions to be drawn from these facts, Dr. Tyson said, he left to those whose province it was to discuss the important matter of treatment.

DR. H. M. BIGGS said that we had now in our possession absolute proof of the causal relation of the bacillus of Koch to tuberculosis. No fact in medicine is better established than this, with the possible exception of the essential cause of anthrax. The evidence, indeed, answers very nearly to the exactness of mathematical demonstration. It seemed to him that the profession could not too soon do away with the notion, held by many even yet, that heredity and other causes are prime factors in the etiology of phthisis. There is one, and only one cause, and that is the tubercle bacillus. That these other factors have an influence we cannot deny, but this influence has the effect simply of reducing the normal power of resistance in the tissues. In order that infection shall result, it is necessary that the dose of bacilli taken into the system shall have the effect of overcoming the tissue-resistance. Depressed vitality resulting from any cause, and antecedent pathological processes existing in the lungs, will naturally facilitate this action of the bacilli.

He believed that the tubercle bacilli were capable of causing the disease without the assistance of any other factor, provided that a sufficiently large number of them entered the system. Heredity, then, means, not the transmission of a predisposition to tuberculosis, but that tuberculous patients transmit to their offspring organs which are easily acted on by such agents as the tubercle bacillus; in other words, organs which have a less resisting power than those of robust individuals. In such organs there is simply an absence of strength, and not the positive possession of unfavorable qualities. It seemed to him that this was a very important point.

If these views are accepted, it follows, first, that phthisis pulmonalis is distinctly contagious; and, secondly, that it is a distinctly preventible disease. The great question that lies before us, therefore, is the prevention of tuberculosis, and he thought that in trying to solve this problem we cannot too strongly insist upon the fact of the single cause of the disease. In the work of prevention all discharges from tuberculous patients should be disinfected, and all tuberculous animals should be destroyed; and we can only hope to carry out such a work by educating the profession and the public in the belief that the disease is due to a single cause. Whether tuberculosis occurs either in animal or man, the fact must be absolutely recognized that it is invariably the result of tuberculous disease existing in some antecedent case.

DR. H. P. LOOMIS said that there was one point to which Dr. James did not allude, and in regard to which he thought it important that something should be said. In the subjects of phthisis there may be what may be called a pre-bacillary condition of the system. It is a

condition of depressed vitality, about which we know very little, and it would seem to afford an excellent field for useful investigation by competent observers. As contributing to this condition we may have heredity, alcoholism, and other depressing influences; but, in addition, in order that tuberculosis should occur, we must have the spark to kindle the flame, and that spark is the specific bacillus. Dr. Loomis said that in confirmation of Dr. James's observations as to the dead-house of the New York Hospital, he could state that he had found that in no less than sixty per cent. of all patients who died at Bellevue Hospital there were old tubercular changes recognizable in the lungs.

DR. TRUDEAU, of Saranac Lake, exhibited some interesting specimens, among which was a copious growth of tubercle bacilli on a piece of potato, illustrating the fact that the bacillus could be cultivated on vegetable, independent of any animal, structures. He also exhibited the lungs of a number of rabbits which were the seat of well-marked tuberculosis as the result of inoculation. He stated that it was possible to produce in animals any kind of phthisis that was known in the human subject by properly regulating, first, the quantity of virus employed; second, the site of the injection, and, third, the environment of the animal. Acute miliary tuberculosis, for instance, could be caused by inoculating the vein of the ear. The animal would die of the infectious disease in about twenty-five days, and an examination would show the presence of tubercles everywhere in the body. By injecting the virus into the apex of the lung a condition would be produced in which fibrous tissue would be found to predominate over the tubercular.

DR. W. H. THOMSON read a paper on

THE INFLUENCE OF THE MICROBE THEORY ON THE TREATMENT OF PHTHISIS.

Having given a sketch of the investigations of Villemin, published in 1865, and of the observations and arguments brought up in opposition to them by Cohnheim, Wilson Fox, and others, he said that the specific nature of tuberculosis was fully reëstablished by the experiments of Klebs, and that with these experiments as a basis sodium benzoate was employed for the purpose of destroying the specific bacteria, whatever they might be, a considerable time before the discovery of Koch. As soon as Koch's conclusions were announced all sorts of so-called germicidal remedies came into vogue, and Dr. Thomson spoke particularly of the use of salicin and iodoform. In every case of phthisis in his service at Bellevue and Roosevelt Hospitals in 1885 and 1886, he employed the latter agent; but as he never met with a single case which seemed to be in any way affected either by its administration or its withdrawal, he then abandoned it entirely.

He said it would only take up time uselessly to speak of Bergeon's short-lived sulphuretted hydrogen treatment and of the use of such agents as tannin, acetate of lead, creolin, and creasote. Personally he had never expected any specific treatment to be of permanent value on account of the organic character of the tubercle bacillus. He had never seen a case of smallpox, measles, or other specific disease that was shortened a single day by the administration of an antiseptic or any other agent whatever. To use a homely simile, we did not know of anything that could be employed by the farmer which would kill the weeds but not the potatoes in his field; and in like manner we could not expect to find any agent that would kill the tubercle bacillus in the body and yet not do injury.

But at the same time Koch's great discovery was not barren of practical results. There is an apparent interdependence of bacterial growths upon each other. That the bacillus needs the assistance of other bacteria in order for it to develop is not often suggested; but Dr. Döllinger has shown that thirteen different forms of bacteria are concerned in the putrefaction of meat, which do their work not so much simultaneously as successively. The streptococcus pyogenes is the most widely distributed microbe known in pathology; so that it may be doubted whether any process in which suppuration takes place ever occurs without it. It is therefore met with in puerperal fever, diphtheria, scarlatina, pneumonia, etc., and the facts go to prove that this organism only needs an entrance into the body to infect the whole system. May not this pave the way, as it were, for the tubercle bacillus, which without its aid would not find a suitable soil for its development?

If this is so, it is of the greatest importance, first, to check all suppurative processes in the lungs; second, to remove the pus; and, third, to prevent putrefaction of pus. One of the best agents against suppuration is creasote, and this may be used both by inhalation and internally. Dr. Thomson related two cases of phthisis with well-marked cavities in which permanent recovery followed the use of creasote. He then said that while he had, of course, met with many cases in which this agent did no good, he believed, on the whole, it was of more efficacy than any other. The second indication was to cause as far as possible a limitation of the tubercular process by promoting the power of resistance in the tissues. In concluding, Dr. Thomson spoke of the difdifference between the physical peculiarities of the subject of phthisis and those of the subject of chronic bronchitis. This contrast, he said, existed before the development of a single symptom, but became more and more marked as the two diseases progressed. It seemed that such patients were born each for his own complaint, and acted accordingly. If by such a study we might be able to strengthen the constitution, he thought it would be of service.

DR. L. WALDSTEIN having stated that he agreed in the main with Dr. Roosevelt as to the diagnostic value of the tubercle bacillus, related the case of a young German whose general condition was poor and who suffered from cough and profuse expectoration. He had been treated for bronchitis, and the examination of the sputum produced negative results. The examination of the chest also failed to develop any positive evidence of phthisis. At length, however, after several examinations of the sputum, some tubercle bacilli were detected. The patient was then sent to Davos, and the climatic treatment had proved in a measure successful. He had met with other cases where not a single bacillus could even be found in the sputum, and yet where all the other symptoms presented positive evidence of grave pulmonary trouble. Relative to the subject of prognosis he mentioned the case of a young man of twenty-one who, while apparently perfectly well, was seized with a copious hemorrhage from the lungs. It so happened that three or four weeks before this occurrence Dr. Waldstein had made

a careful physical examination of the patient, who desired to take out a life insurance policy, and the results of this were entirely negative as far as the presence of any disease was concerned. Other hemorrhages quickly followed the first, and after these the sputum presented almost a pure culture of the tubercle bacillus. The patient was then sent away, and he afterward made a complete recovery, so far as any signs of disease remained. The cough and expectoration ceased, and repeated examinations had failed to detect any bacilli. Yet no competent physician would pronounce this patient cured, for one could not say what might be found in after years. He thought, therefore, that Dr. Roosevelt was right in saying that the evidence of tubercle bacilli was valueless as regards prognosis.

DR. B. F. WESTBROOK, of Brooklyn, thought that some of the gentlemen who had preceded him had overstated the case. The tubercle bacillus was not the only cause of tuberculosis; and, while it might, perhaps, be the only exciting cause, there were other important causes besides this exciting one. The others, indeed, were the more important. As to the matter of diagnosis, also, he thought the actual facts had been somewhat overstated. Personally he had never seen a case where the bacillus was present in which he could not make a positive diagnosis of tuberculosis without its aid. A skilful examiner, he believed, could always make the diagnosis in any case where a microscopist could do so by means of the sputa. In cases of pleurisy at the apex of the lungs, however, where it was not known whether tuberculosis originally existed or not, he thought the examination of the sputa would often prove of value. A few cases were also met with in which patients with weak chests have some crackling at the apex and the diagnosis is somewhat doubtful, because emphysema may present precisely the same signs as tuberculosis. In these, too, the presence or absence of the bacillus would be of considerable diagnostic value.

As to the matter of prognosis, if in any case repeated examinations failed to reveal the presence of bacilli in the sputum, he would conclude that there was no tuberculous trouble, and that the case was probably of chronic interstitial pneumonia. The mere numerical quantity of bacilli found in any case was, in his opinion, of no value. As regards the matter of treatment, he believed that the only influence that the discovery of Koch had upon this had been pernicious. It had resulted in the introduction of all sorts of michievous methods. There could be no specific treatment unless we could discover a specific antidote. Antiseptic agents, however, might be of great service in the treatment of fetid bronchitis, in cleansing and disinfecting cavities and the bronchial tubes, and in fortifying the constitution of the patient.

DR. F. P. KINNICUTT said that some of the antiseptic remedies had an undoubted value in removing foci of irritation and rendering the tissues aseptic. They arrested fermentation and had a stimulating effect upon the vital processes; and it was no doubt to such effects that the benefit noticed from the use of creasote was due.

EIGHTH GERMAN CONGRESS OF INTERNAL MEDICINE.

Held at Wiesbaden April 15th to 18th, 1889.

(Specially reported for THE MEDICAL NEWS.)

The Eighth German Congress of Internal Medicine held its first meeting on Monday, April 15th, under the presidency of Professor Liebermeister, of Tübingen.

DR. LEICHTENSTERN, of Cologne, read the first paper, which was on the

PATHOLOGY OF ILEUS.

In the most ancient writers on medical subjects will be found allusions to ileus; but our most valuable knowledge on this subject is of more recent date, when our mode of investigation had become more rational, and our anatomical studies more certain. Ileus was considered by Mercurialis as an inflammation of the ileum, as colic was regarded as an inflammation of the colon. Later, the designation of ileus was applied to the rejection of feces by the mouth, for some cause of intestinal obstruction. This definition, which we owe to Heurnius, has been accepted by medical scientists, and has been progressively completed as our knowledge of the affection has become more precise.

To-day, we understand by the term ileus a grave and complex train of symptoms which develop when there is intestinal obstruction, due to some mechanical obstruction, or to a paralysis of the unstriped intestinal muscular fibres. The ileus can be divided, according to its mode of formation, into: 1. Mechanical ileus; 2. Paralytic ileus; still oftentimes both these mechanical and paralytic causes coexist, and one can even say that in the majority of cases these two processes of obstruction contribute to the development of the symptoms which are so varied in this disease. The stenosis of the intestinal canal, whether due to a mechanical cause or to a paralytic process, can manifest itself in a very sudden manner, such as the passage of a gall-stone, and we then have a train of symptoms indicative of acute ileus. Still, the sudden appearance of these symptoms does not mean that this stenosis is of immediate formation, for this contraction might have taken place progressively, and have persisted a long time without any notable influence on the general health, until the day when, for some unexplainable cause, perhaps, the compensation which resulted from the muscular hypertrophy developed in the part of the intestine situated above the stenosis, is suddenly interfered with. This stenosis can remain in a latent form, as the contraction of the unstriped muscular fibres situated above the stenosis would suffice to allow the feces to pass.

Amongst the causes which can bring on this more or less latent stenosis, we can mention peritoneal bands, adhesions of the ileo-cæcal or vermiform appendix, or any changes in the uterus and neighboring parts. As a matter of fact, acute intestinal obstruction is always accompanied by a paralysis of the intestinal fibres, and consequently the ileus is not a purely mechanical one.

The symptoms of ileus are local and general. They come on suddenly or progressively, according to the state of the stenosis, whether it is more or less permeable, and according to the point at which the lesion has taken place. In the Galen school, the fecal vomiting was interpreted on the theory of the peristaltic movements. Morgagni

greatly contributed to sustain this theory when he demonstrated that normally the intestinal contents of the colon have already lost as much water as when they come out of the rectum; since this demonstration, it has been admitted that the fecal vomiting was composed of the contents of the small intestine, which being compelled to stagnate there, on account of the obstruction, underwent a putrid fermentation, giving to the vomited matter the fecal-like character observed. It has been demonstrated by such authorities as MM. Hoppe-Seyler, Kühne, Jaffé, Bowmann, etc., that in the vomited matter, in cases of ileus,the presence of chemically determined products encountered in putrid fermentations were easily discernible, even the presence of the bacteria of putrefaction has been demonstrated.

We must, then, draw a definite line between the fecal vomiting which is very exceptionally met with, and the fecaloid vomiting, which does not consist of real fecal matters, but of fermented intestinal contents, as a result of stagnation above the occlusion, and impregnated by an odor like that of the real feces, but developed in the *small* intestine and not below it. The vomiting can be of a fecaloid character even if the matters come from the upper part of the ileus or jejunum, as has been demonstrated by the observations of Kahler, in Germany, and of Cossy, Larguier, and Besnier, in France, who think it possible to conclude, according to the early or late appearance of the vomiting of fecaloid matter, as to the actual seat of the obstructive lesion.

The antiperistaltic theory has been abandoned later for the hydraulic theory, which, up to date, has had many partisans, although it has been severely combated by Van Swieten, Morgagni, and Haller. It is to Haguenot, of Montpellier, that we owe the most complete demonstration of the reality of the antiperistaltic movements of the intestines, and after his experiments, made as early as 1713, a great many physicians accepted anew the antiperistaltic theory. The author made, with Kirschstein, a new experiment to demonstrate the real state of the antiperistaltic movements. After having excised in a dog a section of about ten inches of intestine, then reversing it and reuniting it, end to end, to the cut sections, he killed the animal seven days after the operation, which was made with the strictest antiseptic measures, and prevented the development of any septic inflammation. At the autopsy it was hardly noticeable where the segment had been reversed, and as all the phenomenon of digestion had been accomplished without the least inconvenience, we must conclude that the movements in the reversed segment of intestine must have taken place as in the rest of the intestinal tract, in the same direction; it also establishes the fact that the contraction progressed in this reversed segment in a direction the reverse of its habitual. In dogs in whom concentrated saline injections had been made, Nothnagel was also able to observe antiperistaltic movements.

We are, then, enabled to admit that the products of fermentation developed in the intestine as a result of stagnation of its contents, can produce on its muscular walls the same action as the experimental saline injections, although Bokai, in publishing his experiments in relation to the injection of products obtained from the fecal matters does not mention antiperistaltic movements, and only speaks of intestinal spasm.

Leyden, at the Congress of 1884, presented a patient in whom he had been able to observe antiperistaltic movements, without there being any signs of occlusion. In France, Dieulafoy, Jaccoud, and Briquet have published several observations of fecaloid vomiting in hysterical patients, which led us to believe in the real existence of antiperistaltic movements without intestinal occlusion.

In ileus the fecaloid vomiting can occur from any point of the intestine where the obstruction has taken place, either from mechanical obstruction or from a paralysis of the muscular coat, or, again, from both these causes. The stagnation of the matter in the intestines is the origin of a urinary symptom to which Jaffé has attached a real diagnostic value, for, according to him, indicanuria or phenoluria are only observed in those cases where the occlusion is situated in the inferior portion of the ileum. Meteorism also contributes, on account of its form, variable in different cases, to the diagnosis of the seat of the lesion.

The general symptoms are the result of reflex phenomenon or of auto-intoxication manifestations; in addition to the pain, which indicates about the point of obstruction, there is produced, through the intervention of the sensitive nerves, a series of reflex disturbances which locate themselves on the innervation and vascularization of the involved region itself, at the same time influencing the cardiac activity; hence the origin of collapse, of the sudden fall of temperature below normal, of the cutaneous anæmia, of the abdominal facies, smallness of the pulse, etc.

To it is due also the albuminuria or anuria, or the disturbances of respiration, which are also helped by the presence of meteorism, cold sweats, etc.

The nervous system contributes to the symptomatology by localized or generalized contraction, by delirium, coma, and a variety of tetanic accidents which are analogous to those observed in certain ovariotomies; several of these nervous symptoms are allied to disturbances of the circulation, which produce anæmia of the brain, or to phenomenon of fecal herniæ.

The introduction into the lymphatic system or veins of putrid matter, developed from stagnant intestinal contents, is often favored by necrotic products, which can occur at the obstructed spot, and which will produce, in such cases, an auto-intoxication which can be compared to typhus cholera. There is a great diminution in the quantity of water contained in the blood, which can explain in part, as in cases of cholera, the interference with the circulation and the weakening of the cardiac contractions. This reduction of the quantity of water found in the blood is due to vomiting and to intestinal hypersecretion. Malgaigne has studied such a type under the name of *hernial cholera*, and Moreau and Hanan have shown that a section of the mesenteric nerve fibres produces a considerable amount of liquid in the intestines, while Cohnheim saw an example of paralytic hypersecretion.

The knowledge of these symptoms will enable us to make a correct diagnosis, to distinguish the ileus from other affections which are liable to simulate it, such as symptoms produced by utero-ovarian lesions, the inflammation of a testicle located in the inguinal canal, enteralgia enteritis, and especially perityphlitis and peritonitis, which can be accompanied by a paralysis of the intestinal fibres. The next diagnostic step is to find out the

seat of the occlusion. In this respect it may be well to remark that, when the occlusion is situated in the upper portion of the small intestine, the abdominal wall is contracted, while in the other cases the abdomen is uniformly distended, with a depression in the regions of the ascending and descending colons. Moreover, if the occlusion has already existed for some time, the increase or swelling of the intestine itself produces a certain number of projections on the surface of the abdomen.

When the lesion occupies the lower part of the small intestine, the constipation will have been more prolonged before the appearance of the symptoms, and the late appearance of the fecaloid vomiting and the gradual development of reflex symptoms contribute to establish the diagnosis of the seat of the lesion.

DR. CURSCHMANN, of Leipzig, then read a paper

ON THE THERAPEUTICS OF ILEUS.

Surgical treatment cannot always be applied in ileus on account of the excessive intraäbdominal pressure, due to meteorism, etc. In this respect we must distinguish, on the one hand, the cases in which ileus is characterized by very marked meteorism and by a great weakness in the cardiac contraction; on the other hand, cases in which these symptoms do not exist. In a female suffering from an ovarian tumor, we can always undertake a laparotomy if the general state of the patient is good; while in persons under the influence of a general state as described above, such a procedure would be fatal in its results.

In cases of ileus, also, we might be compelled to make a very careful and very prolonged exploration of the suspected intestinal obstruction. In those cases, it can be well understood, laparotomy would only help us if the diagnosis of the seat of the lesion had previously been carefully determined. On the contrary, every time that we are certain of the diagnosis—that we know the seat and anatomical cause of the lesion, we must resort to the operation as early as possible.

The statistics of ileus, even if the treatment has remained an exclusively medical one, is not of so an unfavorable prognosis as is ordinarily admitted. Out of 105 cases, 50 of which were the author's, the number of cures without the intervention of the surgeon was 35.5 per cent. In the medical treatment purgatives must not be allowed, for they rapidly weaken the patient; they also increase the secretions, and consequently the abdominal pressure, producing, therefore, an increase of the paralysis of the muscular fibres. The author always begins by giving his patients about 0.5 gramme to 1.5 gramme of opium in the twenty-four hours; which medication is immediately suspended when dangerous symptoms of muscular paralysis of the intestine occur. Washing out of the stomach with the stomach-pump acts as a palliative, and is curative also, diminishing the pressure in the stomach, and from thence in the intestines. Gaseous injections in the rectum must be used to immobilize the diseased intestinal segments, and eight to ten punctures with the hypodermatic syringe, here and there, can also contribute to give more freedom to the involved intestine and help the final cure as much as possible.

DR. JURGENSEN, of Tübingen, agreed with the treatment of intestinal obstruction described by Dr. Curschman; yet there are certain points which he could not allow to pass, such as the treatment and efficaciousness of gaseous injections into the rectum. He did not at all believe in the efficiency of treatment by these injections, for the following reason: if we inject into the rectum of a dog a certain quantity of atmospheric air, we find that the intestines, being dilated, compress themselves mutually, and if at that moment we measure the arterial pressure, we find that it is very much reduced, and that the oxygenation of the blood is very much interfered with, the blood withdrawn from an artery presenting all the characters of venous blood; from this he concluded that gaseous injections in the dog result in a great lowering of the arterial pressure and a diminution in the oxygenation of the blood.

What takes place in a man suffering from intestinal occlusion, his breathing being already very much interfered with? A gaseous injection can only increase this respiratory dyspnœa, and death will occur very rapidly; we also know that death by heart-failure is of common occurrence in ileus. He concluded by saying that he did not think it at all necessary to increase the chances of death of an individual suffering from intestinal obstruction, by giving him gaseous injections.

DR. ROSENBACH, of Breslau, said that in cases of intestinal occlusion he thought it necessary that the urine of the patient should be carefully examined; a certain quantity of nitric acid is added to the urine and shaken for some time; if the reaction indicates the presence of a great quantity of urobilin, this becomes of very great importance in a diagnostic as well as in a prognostic point of view. The presence of urobilin in the urine indicates a great interference with the nutritive changes, which interference is due to mal-assimilation of the ingested albumin; we have here a phenomenon of inanition by intestinal insufficiency, for the resorption of intestinal matters in a state of putrefaction has nothing to do in this matter. The eliminated organic matter is formed in this case by the albumin which is held in reserve in the human body; the reaction is an important one, as it demonstrates an anomaly in the molecular changes. By the use of this test any anomaly is easily discernible.

If, after fourteen days, this reaction still persists, it indicates that we have to deal with an intestinal disease which will prove fatal in a very short time; this has been shown by clinical experience, and the persistency of this reaction contraindicates absolutely any surgical interference. As to the intestinal punctures, he thought them excellent; but they must not be made with a trocar, no matter how small it may be; the best instrument to be used is, without doubt, Pravaz's hypodermatic syringe; several punctures must be made at the same time in different places, going from one side of the abdomen to the other, for the intestinal pressure is unevenly distributed along the whole length of the intestinal canal; in all his experiments he had always found the intestinal pressure to be higher on the right than on the left side; hence, the right hypogastrium ought to be the region more often punctured.

PROF. NOTHNAGEL, of Vienna, said that if the peristaltic movements are very great, invagination will produce itself without giving rise to symptoms of intestinal occlusion, such as are ordinarily presented. He did not believe in invagination as a frequent cause of intestinal obstruction, nor did he believe in the antiperistaltic

movements of the intestine; whenever he has injected great quantities of a concentrated saline solution into the œsophagus of a dog, he has never seen any antiperistaltic movements, and these spasmodic actions of the intestine he had observed only where he excited the intestine itself.

Prof. Ziemssen, of Munich, demonstrated formerly that gaseous injections are not so dangerous as was stated to-day, but they must be made with care, for the air can pass through the obstacle and acting upon the upper part of the intestine, bring on vomiting. He had seen in two cases fecal vomiting, which had been diagnosed intestinal obstruction; at the post-mortem a communication between the transverse colon and stomach was discovered and the fecal matter passed from one to the other. One case was a round stomach ulcer; the other a carcinoma of the same organ. As regards treatment, I do not believe at all in internal medication, as drugs are not absorbed by the intestines. At the age of twenty-eight years, he suffered from an ileus; opium given by the mouth had no effect, opium enemata alone gave him some relief. Rosenbach has well demonstrated this fact of the non-absorption of drugs by the intestines under the conditions just named.

In addition to the above treatment, he thought it well to puncture the intestine several times. He had made as many as sixty-eight punctures at one sitting, using an ordinary well-sterilized pin, and he was sure that these punctures have a favorable influence on the course of the disease.

Surgical intervention he thought sometimes a dangerous proceeding, as he had seen a patient under chloroform suddenly taken with vomiting of fecal matter, which penetrating into the respiratory passage produced sudden death.

Prof. Immermann, of Basle, then read a paper on

THE FUNCTIONS OF THE STOMACH IN PULMONARY TUBERCULOSIS.

He said that the treatment of all the chronic infectious diseases, such as tuberculosis, must be carried on in a new direction, since the researches of Metschnikoff on the fight which takes place between the cells and the microörganisms which invade the human economy. For this reason we find that Debove in France, Dettweiler and Bezold in Germany, have tried to place the organism in the best possible conditions to enable it to defend itself against the tubercle bacillus. The natural feeding of the phthisical patient is somewhat difficult, on account of the absolute distaste for food which certain phthisical patients have, even at the very beginning of their disease.

If the physician, however, is persevering, he will be able to force the patient to take a really large quantity of food; this is the process recommended by Dettweiler. Immermann's studies have been directed to the study of the physiology of digestion as encountered in phthisical patients; the variation therefrom had been named by Dettweiler as the nervous dyspepsia of phthisis.

As a result of his experiments, he has found that in nearly all the tubercular patients he has had to treat, the stomach was in a normal physiological condition; moreover, the state of the stomach seems to be absolutely independent of the more or less advanced state of the pulmonary lesions; the gastric juice remains the same. There is, perhaps, an exception to be made for the tuberculous patients suffering from hectic fever, and even in such cases the function of the stomach is interfered with on account of the application of the law of general pathology which shows that the stomach functions are very much interfered with in all febrile states of the organism. He published the result of twenty-five observations, in Virchow's *Archiv*, last year, showing that in all these cases the digestive powers had been absolutely maintained, and since this communication his observations have continued just as conclusive. He maintained that in phthisical patients the functions of the stomach remain perfect.

For the purpose of studying the digestive power of the gastric mucous membrane in such patients, he employed the stomach-pump fifty-five times. In fifty-one cases he found the stomach absolutely empty six hours after the last meal; moreover, the digestion was normal even where it seemed impossible that it should be so. In a certain patient who had enormous pulmonary cavities, broken-down cachetic state, no appetite, in the midst of his hectic fever digestion was going on perfectly.

His next series of experiments was made on forty-five patients; after fasting twelve hours a large meal was given to them, and he then, by the aid of the stomach-pump, examined the composition of the gastric juice. It presented the reaction of Gunsburg, which consists in reducing aniline by hydrochloric acid in thirty-eight cases. The quantity of hydrochloric acid found varied from 1 to 4 per 1000, and this even in the most advanced cases of phthisis; moreover, no traces of lactic or butyric acid could be found. In six of his patients the aniline test remained negative, and the extract obtained was not acid. This establishes the fact that in phthisical patients the quantity of the hydrochloric acid is not below the average of the gastric juice of a normal stomach. Having demonstrated the presence of hydrochloric acid, he next studied the amount of pepsin; for this purpose, every morning and evening he aspirated from the stomach of a phthisical patient a certain quantity of gastric juice, and he then placed two three little disks of albumin of about two to four millimetres in thickness in this liquid, and in a culture stove. When the test of Gunsberg existed it took about one hour for the digestion of these small disks.

In conclusion: there is really no dyspepsia in pulmonary phthisis, it does not belong to this affection, and if present, is more to be regarded as a complication. The inappetency or dyspepsia of tubercular patients has no connection whatever with the anatomical or physiological state of the gastric mucous membrane, and one must not attach a too great importance to the morbid symptoms, which really do not belong to the stomach.

(To be continued.)

NEWS ITEMS.

A Judge's Opinion on the Use of the Title Homœopathist. —Judge George C. Barrett, of the Supreme Court of New York, sends to the *New York Medical Times* an opinion which will be read with much interest. He was asked to give a reply to the question: "Has a physician designating himself an 'homœopathist' and called as such to a patient, any legal or moral right to adopt other than

homœopathic means in the treatment of the case?" To this Judge Barrett answers: "I have your note of the 11th inst., asking my opinion upon a question of professional ethics. In my judgment there can be but one answer to your question, and that in the negative. If I call in a medical man who designates himself a 'homœopathic physician,' it is because I do not wish to be treated allopathically, or eclectically, or otherwise than homœopathically. There is an implied understanding between myself and the homœopathist that I shall receive the treatment which, by tradition and a general consensus of opinion, means small doses of a single drug administered upon the principle of *similia similibus curantur*. If there is to be any variation from that method I have a right to be informed of it and to be given an opportunity to decide. Common honesty demands that before a confiding patient is to be drugged with quinine, iron, morphine, or other medicaments, either singly or in combination, he should be told that the 'homœopathist' has failed, and that relief can only be afforded by a change of system. An honest 'homœopath' who has not succeeded, after doing his best with the appropriate homœopathic remedies administered on homœopathic principles, should undoubtedly try anything else which he believes may save or relieve his patient. But when he reaches that point the duty of taking the patient into his confidence becomes imperative. The patient may refuse to submit to the other system or he may agree, but prefer a physician whose life has been specially devoted to practice under that other system. He may say to the 'homœopathist,' 'You have failed, but I prefer to try another gentleman of your own school, before resorting to a system that I have long since turned my back upon.' Or he may say, 'Well, if homœopathy cannot save me, I prefer to go to headquarters for allopathic treatment.' All this, gentlemen, is the logical sequence of the particular designation 'homœopathist.'"—*Medical Record*, May 4, 1889.

Medical Men and their Remuneration.—A curious case will shortly come up for trial in a law court in Saxony, the result of which will scarely fail to be interesting to most practitioners. A medical man was in attendance upon the wife of a rich man in Saxony. The patient was exceedingly ill, and her husband was naturally extremely anxious. For the purpose, as it would seem, of stimulating the best energies of the practitioner, the husband promised, if his wife recovered, to give half his fortune to the doctor. The circumstances were propitious for the patient, and her health became established; in short, a complete cure was effected. This result having occurred to the entire satisfaction of the husband, the latter forwarded in the course of time a large sum of money in requital of the practitioner's services. The doctor, however, refused to accept the sum in question, and claimed as his reward the moiety of the fortune which had been promised him. The rich man's fortune was equal to £100,000, and although he seems to have agreed to dispose of half of this amount to the medical man in the event of the recovery of his wife, he now refuses to carry out his promise which he had given, and repudiates the claim which is being made upon him.

Thus the aid of the law is about to be sought in order to determine the point in dispute. The case for the doctor will, in all probability, entirely depend upon the legal evidence which he is able to produce of the agreement. It is scarcely to be supposed that any feeling of sentiment will be allowed to influence the result. The rash promises which are made in the presence of medical men, either by patients or their friends, is matter of almost common occurrence, under certain circumstances, while the rapid declension of that feeling which is called gratitude, after the danger is past, is proverbial, as far as the practitioner is concerned. In connection with the case above narrated, the doctor, if successful in securing £50,000, will be able to pride himself upon receiving the largest fee which has ever been paid to a medical man; but, generally speaking, it would require a sanguine person to believe that legally the rich man will be compelled to make good the promise into which he seems rashly to have entered.—*Medical Press*, April 3, 1889.

In Memoriam.—At a meeting of the Philadelphia County Medical Society, held April 24, 1889, the following minute was unanimously adopted:

By the death of DR. SAMUEL W. GROSS this Society has lost an industrious colaborer, a wise counsellor, and the profession one of its most brilliant ornaments. As a student, practitioner, and teacher, he possessed, with remarkable surgical acumen, unusual powers of analysis and deduction, and his lectures, like his mental workings, were conspicuously clear, concise, logical, and vigorous. He was an earnest student of the progress of surgery in all countries, with more respect for the experience of the present than the traditions of the past, never satisfied to stand still and ever advancing with the progress of science, he kept his teaching always apace with the rapid strides of surgical knowledge. As an operator he was bold, conscientious, and successful. Possessed of broad views, he was quick to recognize merit and to welcome truth by whomsoever presented. He took an active interest in all that pertained to the welfare of the profession and was ever ready to work for its promotion. He possessed positive convictions and was frank in their expression. As a companion he was genial and entertaining, as a friend generous and true.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 30 TO MAY 6, 1889.

BORDEN, WILLIAM C., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Ringgold, Texas, and ordered to report to the commanding officer at San Antonio, Texas, for duty at that post.—Par. 7, *S. O. 100, A. G. O.*, May 1, 1889.

FISHER, WALTER W. R., *Captain and Assistant Surgeon.*—Is hereby granted leave of absence for one month.—Par. 1, *S. O. 30, Headquarters Department of California, San Francisco, California*, April 27, 1889.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

THERAPEUTICS OF THE GOUTY DIATHESIS.

From a Lecture delivered in the Polyclinic Evening Lecture Course, March 12, 1889.

BY SOLOMON SOLIS-COHEN, A.M., M D.,

PROFESSOR OF CLINICAL MEDICINE AND APPLIED THERAPEUTICS, PHILADELPHIA POLYCLINIC; LECTURER ON SPECIAL THERAPEUTICS, JEFFERSON MEDICAL COLLEGE, ETC.

RECOGNIZING from the facts we have thus far considered, that it is not a disease—not a sudden or a gradual departure from the usually normal action of the organism—that we are dealing with; but that it is, if I may be permitted the expression, an abnormal normality; that is to say, an inherent departure of the individual organism from the typical action of like organisms; we see that our treatment is of necessity directed to permanent conditions, and must be of a permanent character. Our aim then, is not so much to alter the action of imperfectly functionating organs—though this must be, to a certain extent, part of our plan—but so to arrange the materials upon which that action is performed, and so to deal with the resultant products as to obviate the further disturbances of the economy arising from the presence in the circulating medium of irritant or toxic matters, or of matters not directly toxic, but still negatively harmful by their exclusion of others needed to promote proper function, or of matters detrimental to general health, by throwing an added burden upon excretory organs to secure their removal.

Repeating then, that it is not "gout," not the storm of diseased action finding its vent in articular inflammation with febrile reaction, which we are now considering, but the "gouty diathesis," the inherent tendency on the part of certain organisms to depart from the normal type of their kind, in the functions particularly of secretion and excretion, and, to a certain extent, of respiration; a tendency not confined to any one organ or set of organs, but influencing more or less markedly every cell of the body, and, in particular, muscles and blood-making and depurating organs; let us see what are the particular objective points of therapy, and in what manner these can be best secured.

Through the teachings of the greatest biologist of the century, we have come to recognize that life is maintained by a continual adjustment of the parts of the organism to each other, and of the organism as a whole to its environment; and as a corollary that a perfect, harmonious adjustment constitutes health, an imperfect, discordant adjustment constitutes a want of health. If every departure from ordinary action of one organ was met by a compensating departure of other organs, and in such a manner as not to impair the harmony between the whole organism and its environment, then such departures would not constitute disease. It is, therefore, theoretically conceivable that the failures of assimilation and excretion, which we collectively group under the title "gouty diathesis," can be completely harmonized by automatic action of the organism, and be consistent with a state of perfect health. Practically, however, the conditions requiring adjustment are so numerous and so involved that while in a great many instances comparative health is maintained for prolonged periods, sooner or later a variety of disturbances, more or less marked and more or less serious, are brought about; so that it is important to impress upon the patient that the condition, be it what it may, for which he seeks relief, is not a temporary matter to be cured by temporary expedients, but the sign of a profound organic alteration, and as such demanding permanent attention. The first point in therapy then, is to gain the intelligent coöperation of the patient.

We must next endeavor to determine to what extent the organic alteration of tissues and functions has been developed in the individual case before us; and in how far this is removable, and in how far it is a permanent life-condition. This is an extremely difficult problem, and can only be solved by careful study of all the symptoms, the temperament, general physical condition, and, as far as can be learned, the personal and family medical history of the patient. It does not fall within our present limit to discuss this extremely interesting question of therapeutic diagnosis. We must assume that it is determined, and choose a representative case as illustrative of the general course to be pursued; with such modifications in other cases as individual conditions may indicate.

Suppose then, that we have decided—as in a case I now have in mind, and of which I will endeavor, for the sake of a concrete example, to present in brief the salient characteristics—that there is a congenital tendency to the over-production of uric acid and to excessive waste of phosphated tissues—a conjunction extremely common—that can never be entirely overcome; but that the results of this tendency are greatly aggravated by the mode of life of the patient and by his mental characteristics. We have first to remove the removable, remedy the remediable; that is to say, reduce the nervous wear and tear and in general alter our patient's mode of life to harmonize with the impaired structure he has inherited. This being done, we must endeavor to secure prompt elimination of the excess of uric acid, whose formation we cannot altogether prevent, and also to check the excessive waste of phosphates and repair their loss.

The patient is an attorney in active practice, of middle age and of nervo-sanguine temperament. A hard student, he takes but little physical exercise—perhaps walks to his office in the morning, if he rises early enough—but is, as a rule, a late riser, because he always goes late to bed. His breakfast, he says, is "light," because he has little appetite in the morning; but the dish of oatmeal, or some porridge equally difficult of digestion, is always eaten. His luncheon at a restaurant is in reality a more than sufficient dinner. It is eaten none too

leisurely, and immediately thereafter he rushes back to his business. In the evening his dinner at home is an elaborate meal, to which a sufficient time is devoted; after which, however, he feels heavy and oppressed. Nevertheless, he will frequently devote his night, sometimes into the small hours, to reading and writing; or if he has gone to the theatre or some social affair, take up his books and papers on returning home.

At breakfast, then, this man eats too little, at luncheon and dinner a great deal too much, his physical exercise is insufficient, his mental exertions too great. In addition, the character of his food is entirely unsuited both to his inherited constitution—his father was the subject of gout—and to his mode of life. He does not need much animal food, for he makes little demand upon his own muscular apparatus; and while we cannot hold strictly to Liebig's classification of foods into tissue-formers and heat-producers, there can be little doubt that nitrogenous foods, as a rule, are devoted to tissue-formation and to the furnishing of those explosive compounds by which muscular activity can be suddenly liberated in response to nervous impulse. It is also true, within certain limits, that nitrogenous foods increase the formation of urea and uric acid, a tendency we desire to restrict and modify.

Yet meats of various kinds form absolutely the greater part of our patient's diet. Furthermore, his inactive life does not make very great demands for heat as a source of mechanical action. Beyond that necessary to supply the force required to keep up the functions of organic life, and a little extra demand for increased cerebral circulation, he needs no particular store of heat-producing elements. Of the carbohydrates, besides, sugar is a direct excitant of uric acid formation; therefore, this must be cut off entirely, and the starches easily converted into sugars reduced to a minimum. On the other hand, the great waste of phosphates, due to congenital tendency and to excessive nervous action, needs repair, and a sufficient amount of fat, of hydrocarbons, must be taken to enable the economy properly to perform its functions with the least possible expenditure and friction. The fat is useful not only as a heat-producer, but in another way. It would, of course, be an extremely crude and inaccurate view of nerve-tissue formation to represent it as a mixing of phosphates and fat—yet nerve tissue is largely phosphorized fat, and by whatever processes of metabolism its structure is built up, consumed, and renewed, I am sure, from clinical observation in just such cases as the one in point, that fats and phosphatic foods do assist in giving it proper tone and diminishing its waste. The good effects of cod-liver oil and of the hypophosphites in improving the nutrition of phthisis, must be in great measure attributable to improvement of the trophic nervous system.

But there are, in addition, other and more easily demonstrable reasons for diminishing the amount both of meat and of sugar and starchy foods, than those already suggested.

The vertigo, the disturbances of vision, the headache, the inability to concentrate attention upon his work, the throbbings, the pains here, there, and elsewhere, the disturbance of the heart rhythm, the condition he terms "torpidity of liver," for which the patient seeks relief—that condition, in a word, which tortures the patient with dread of impending mental failure, and which by physicians is so often carelessly mistermed "neurasthenia"—is to be ascribed not alone to the overloading of the circulation with uric acid, but also to direct and indirect impoverishment of the blood, from faulty assimilation due to failure of digestion. Too great a demand is made upon the digestive apparatus, and the energies that should be directed to other work are called upon to prepare an amount of food far beyond that necessary for purposes of force-production or tissue-building. The work is not done properly; and, as a consequence, the system suffers both from lack of the products of perfect digestion and from overplus of the products of imperfect digestion. Therefore, we must diminish the absolute quantity of food consumed, and must so regulate its quality as to produce the greatest amount of force with the least possible expenditure.

We must, in addition, cut off those elements which, if undigested, are liable to undergo acid fermentation, thus increasing uric acid production. It is a mistake, I think, except in the worst cases, to interdict meat completely. We can allow one kind of meat at one meal, daily; giving the preference to "white meats," but not absolutely excluding butchers' meat. We must insist upon proper cooking—that is, broiling, roasting, or boiling; not too "well done" in the former methods, and not "done to rags" in the latter. Fish can often take the place of meat with advantage. Bread must not be used in excess, and gluten bread, or that made from the whole wheat and retaining the phosphates, is preferable to our ordinary white bread. Pastries and sweets are to be forbidden. Potatoes, turnips, cabbages, and similar starchy vegetables should be cut down to the lowest point, or, better, avoided altogether. Rice, well cooked, may be allowed in moderation. Green vegetables, lettuce, celery, cresses, spinach, asparagus, and the like, may be partaken of judiciously, unless any one of them should give rise to unpleasant symptoms—so, too, the legumens, peas, beans, lentils; preferably in the form of *purée*.

Fruits, if not too acid, may be used freely. If any particular fruit is found to cause indigestion, or to give rise to gouty manifestations, it should be interdicted. Patients are often markedly idiosyncratic in the matter of fruits, and it is impossible to lay down exact rules.

Fat, in the form of butter, cream, oil, or meat fat, should be used in moderate amount. Even in the obese, as Ebstein has more particularly insisted upon, it is a mistake to cut off fats entirely. The quantity must be governed by circumstances; the amount of work done by the patient and the extent to which we are substituting hydrocarbon for carbohydrates must be considered and the results observed. Some careful experiments by Ebstein show that, up to 120 grammes of butter daily, the amount of uric acid excreted by a healthy man was rather diminished than increased by the consumption of fat.

Fluids, and especially water, should be used freely. To speak first of nutritive fluids, milk should be substituted for meat to some extent, and, perhaps, as some claim, absolutely in the worst cases, though personally I have not found it necessary to insist upon entire abstinence from flesh. The so-called "milk-cure" of gout is a delusion and a snare. An exclusive milk diet will harm rather than benefit our lithæmic patients. It is important in these and all other cases that milk be properly used. It must not be gulped hastily, ice-cold, to

check digestion and to coagulate into a great tough curd requiring hours for resolution. Sipped slowly, so as to form minute coagula through which the digestive juices can readily penetrate; and, preferably lukewarm, so as not to lower digestive temperature, the fancied "disagreement" of milk with many patients will not be manifested. From one pint to three pints daily may be taken according to the quantity of other foods permitted. Soups, if not too thick—that is to say, *bouillon* rather than "stock"—should always precede at the principal meal of the day. Like the beef-tea of the sick-room, this is rather a gentle stimulant to the peptic glands than an aliment, and it furnishes also a quantity of warm fluid to help the solution of other aliments. It is almost unnecessary to say that cold water must not be taken with meals. The use of hot water at meals if must be, but preferably an hour before meals, is of signal advantage in gouty dyspepsia.

While excess is injurious, even in the use of water, and while it is beyond question a mistake constantly to overload the vessels, yet a certain amount of flushing at intervals gets rid of noxious accumulations and gently stimulates the kidneys, the skin, and the intestinal glands and mucous membrane to the work of excretion, which it also facilitates by suspension or solution of the offending matters. It reduces in this way the danger of calculous concretions. I am sure that much of the benefit from certain vaunted mineral waters is due as much to the H_2O as to the salts held in solution. The same thing may be said of certain medicinal infusions and decoctions—the real "active principle" is hydrogen monoxide.

When we cannot induce patients to drink water, or when the ordinary drinking-water of the locality is noxious, we can then appropriately order some alkaline spring-water. And this brings us to the question of the administration of alkaline remedies. I can only reëcho the advice of Ebstein—they are to be "used, not abused." Even moderate doses of alkalies are badly borne by some patients; and some require the concurrent administration of a ferruginous or bitter tonic. Carbonates, acetates, citrates—that is to say, salts of vegetable acids—should be employed. Lithium has a preëminent reputation, but I cannot say that it is altogether deserved. I think I have seen equally good results from potassium salts; but ammonium and sodium salts, especially the latter, should, as a rule, be avoided, as having a certain tendency to produce insoluble compounds. Very often it may be found that a combination of two alkalies—for instance, lithium citrate, say ten to fifteen grains dissolved in *liquor potassii citratis*, say two fluidrachms—will give better results than either salt singly.

I have not observed better results from lithium-sodium-benzoate than from lithium and potassium citrates or the potassium carbonates. Potassium acetate, as a rule, does not seem to be equal to the other vegetable-acid salts, though it is an extremely difficult matter to decide positively between the various alkaline medicaments. Lithium salicylate is often of decided benefit, especially where vague myalgia, so-called "muscular rheumatism," has been present. Probably better results are to be obtained by varying the particular drug employed than by constant use of any one salt or of the salts of any one base. I have not seen any great benefit from colchicum in the gouty diathesis, though its value in acute gout cannot be denied.

There are other points in the medicinal treatment which may be more appropriately taken up after a few further matters connected with the regimen of our patient have been considered. He drinks "moderately." But even "moderate drinking" is an excess for a person of gouty inheritance. If possible, we must cut off alcohol entirely. If necessary, the change may be gradual. Malt liquors and sweet wines must be absolutely prohibited in any event. The least injurious alcoholic beverages in these cases are spirits (whiskey, brandy, or gin), and light dry or sour wines.

Exercise, appropriate in its quality and quantity, must be, not vaguely advised, but definitely prescribed. In the prescription of exercise careful judgment is necessary. We must consider not only the patient's physique, but also his occupation, means, and surroundings, and endeavor to give advice capable of practical application, with the least disarrangement to his affairs. Where time and purse permit, horseback exercise, in moderation, is probably best of all. Bicycle or tricycle riding will sometimes answer as well, and is, indeed, an admirable exercise. Open-air walking is within reach of all. In all these the patient, if unused to active exercise, must begin with very little exertion and gradually increase. Where a long and thorough rest can be had after exercise, and where the skin, intestines, and kidneys are in vigorous function, it is well to push it to the point of fatigue; but in the majority of cases it is better to stop short of that point. I have, however, seen excellent results from fatiguing exercise persisted in daily, at intervals, for short periods, a week or ten days at a time.

The use of dumb-bells and other calisthenic measures at home is inferior to open-air walking or riding, but may be associated with the out-door exercise.

As to the matter of baths, opinions differ greatly. Cold bathing is lauded by some, and condemned by others. In this, as in many other instances of disagreements as to therapeutic measures, the fault lies in exclusive regard being paid to the two extremes of a problem, disregarding the very important connecting mean. In other words, we have to consider not an abstract pathological condition or complexus and an abstract remedial action, from which factors we may, as in pure mathematics, deduce an equally abstract and theoretically exact conclusion; but we must also consider the very concrete patient in whom the pathological condition is present, upon whom the remedial action is to be exercised and in whom the result is to be practically manifested. Empirical observation, guided by rational forecast, must then be the determining factor of the problem. In the patients of sanguine, or nervo-sanguine, or even bilious-sanguine temperament, whose robust condition leads us us expect prompt reaction from cold bathing, it may be judiciously advised; and if it produces an agreeable glow with a general feeling of exhilaration, should be continued. On the other hand, it will probably be injudicious in weak or run-down persons, or in those of lymphatic or bilious temperament; and in any case in which it fails to produce an agreeable and stimulating reaction, should not be practised. It is important, however, in all cases to keep the skin in active function. Where cold bathing is ill-advised, lukewarm baths should be frequently taken, and Turkish or Russian baths, if well borne, at intervals of three or four weeks or more, according to indications.

The intestinal functions must also be kept at a proper pitch of activity, not alone that digestion may be properly performed, but that auto-intoxication with leucomaines may not assist the general depressing influences. An occasional saline laxative, Rochelle salts preferably, may be used in case the mineral water habitually or occasionally employed is devoid of mild purgative effect. In some cases, especially where the liver is markedly at fault, probably in a condition of venous congestion, with more or less catarrh of the bile ducts, the acid phosphate of sodium, with an occasional mercurial, will be found to serve a good purpose. Habitual use of active saline or other cathartics, or drastic purgation at any time, is to be deprecated. If there is intestinal atony, or lack of secretion, the remedies usually employed for these conditions, nux vomica, belladonna, rhubarb, euonymin, and the like, may be resorted to in appropriate combinations.

One other remedy, or class of remedies, addressed to the general condition should not be forgotten. At first sight it would appear to be theoretically contraindicated, but at all events there is agreement as to its good effect empirically; and hence there can be no sound theoretic objection. The fault lies in any theory which fails to agree with good practice. This class of remedies is that of the mineral acids, preferably phosphoric or nitric acid; given well diluted in small doses, just before or during meals. While I cannot agree with the opinion that nitric acid, for example, is a direct oxidizer, and while the actual amount of oxygen that could be liberated from the few drops of nitric acid taken into the system would be in itself of no value, yet I have no doubt from clinical observation that this agent not only assists digestive action, but really does, in whatever way, chemical or dynamical, stimulate general oxidizing processes. It may be like the first push to a row of bricks that causes all to topple—initiatory of general oxidation. Surprising improvement often results from its use in so-called neurasthenic patients—in reality the dyspeptic subjects of the gouty diathesis. The inhalation of oxygen would seem to be theoretically indicated. As a rule, a healthy man in moderate physical activity inhales in the air more oxygen than his blood can appropriate. Nevertheless, in some conditions of ill-health, and in the gouty diathesis especially, the occasional filling of the pulmonary cavity with pure oxygen seems to induce greater absorptive activity, whether mechanically or chemically I cannot state. This measure, or the inhalation of compressed air, may then be appropriately employed at times, though such methods can never replace open-air exercise and should not be allowed entirely to substitute the latter.

In the particular case which has served as a thread upon which to string our therapeutic observations, the following treatment was pursued. It will be remembered that the prominent symptoms were vertigo, headache, and confusion of ideas. A large dose of Rochelle salts was ordered for immediate effect, and free purgation with smaller doses continued for a few days, when a pill of euonymin and nux vomica was substituted. For disciplinary purposes, a strict diet of skimmed milk was instituted, the other allowable foods being gradually added. Thus the patient was led to regard as a liberal diet, that against which he would in the first instance have rebelled. As much rest from business as pressing affairs would permit was recommended, and the time thus gained devoted to moderate open-air exercise, walking, and riding.

Warm Carlsbad water slowly sipped before breakfast and before dinner, and the mixture of potassium and lithium citrates three times daily, between meals, was prescribed at first; and with the disappearance of the brick-dust sediment from the urine, dilute phosphoric acid at meals was substituted for the mixed alkalies. The habitual use of the Carlsbad water was recommended. Cool bathing, sea bathing, and occasional Turkish baths were prescribed, at appropriate seasons. Improvement was rapid, and the patient will probably be comfortable as long as he obeys orders.

APOSTOLI'S METHOD OF TREATMENT OF UTERINE FIBROIDS.[1]

BY HORATIO R. BIGELOW, M.D.

THE name of Apostoli will always be associated in the minds of gynecologists with a plan of treatment which he, more than all others, has elaborated, differentiated, and systematized. From an examination of the many and varied diseases which seek surcease from suffering at his hands, lessons have been learned which must bear fruit as the ages go and come. Others will take up the work, and round it out; others may improve upon it, may clear up some of the doubtful points that now surround it; others will add to it wealth of clinical detail, but the glory of it will be Apostoli's long after time has put an end to unfriendly criticism or to personal rancor—and when his name, too, shall be added to those who have created new eras in scientific progress.

The manner of this paper has been a subject of some concern to me. It was a serious question whether I should enter into a discussion of the salient physical and physiological laws that modern investigation has made familiar to most students—whether or not it were better to consider the tributes of theorists upon points which the infancy of electrical science has not had time to substantiate, and a consideration of which would involve much empty speculation; or whether to write in homely fashion of ways, means, and facts, in such wise as to be instructive and convincing. I have chosen the latter, simply premising that he who seeks to do a perfect work in this department must acquaint himself, and that right well, with the great underlying principles of the physical laws of electricity, and of these in relation to their physiological bearings, and that he should have some personal acquaintance with the *feel* and *results* of the different currents in different parts of the body.

I shall have a word to say upon the armamentarium, for no man can wage a successful combat with faulty weapons—then shall ask the reader to go over with

[1] Communicated to the Obstetrical Society of Philadelphia.

me questions of chemical action, of constancy, of tension, and of inter-polar action, and finally we will discuss together the methods of application and the clinical facts demonstrated at Apostoli's clinic.

The armamentarium. — A galvanic battery, a faradic battery, a collector, a galvanometer, intra-uterine electrodes for both currents, and one for carrying both the positive and negative of the induced current within the uterus. Bulbous charcoal-pointed electrodes of various sizes for galvano-caustic applications; intra-uterine platinum electrodes, and large bulbous vaginal and rectal electrodes. The belly plate can be made of potter's clay, in which the metal plate is buried—or better, perhaps, is the plate devised by Martin, of Chicago.

The galvanic battery. A good battery must have—

1. A slight chemical action.
2. Great constancy.

It is well to remember that the *quantity* of electricity is not synonymous with *tension.* With a pile of great chemical action we have always burning pain and lesions of the skin. A number of elements united does not give a larger quantity of electricity than one element, but it gives a *tension* capable of overcoming resistance and of accomplishing results which a single element could not do. Therefore we seek a battery which will generate a current of sufficient *tension* to overcome the obstacle. A battery too, in which the chemical action is great, is expensive, because of the degeneration of material, and it is not reliable in constancy. A perfect pile is one in which—

1. The evolution of gas is avoided.
2. In which there shall be the slightest possible chemical change of the liquids of the battery.
3. In which the metal plates shall not be changed by the deposit of the chemical action.

Constancy, which is the most important consideration for the doctor, can be had by using a rheostat, but as this is expensive and necessitates a great number of elements, it is better to select a battery with a constant pile.

The Leclanché cell. The current is here generated by the action of the chlor-hydrate of ammonium upon charcoal and the peroxide of manganese. These cells have grown to be very popular, and they will give a constant current when in use for 120 to 130 hours, without being recharged. But I do not quite like the combination, since the chemical action is always considerable.

The Daniell element. This is formed of two metals and two liquids: zinc and copper, and water acidulated with sulphuric acid, and a solution of the sulphate of copper. This pile, or the same modified by Dr. Onimus, is one of the very best. It has great constancy and small chemical action. The batteries of the bisulphate or protosulphate of mercury are not useful because of the great chemical action. M. Gaiffé makes an excellent battery of the chloride of silver, which is valuable since it can be used several months. It may be added, however, that after six months of use the elements are destroyed.

The Leclanché cells, or those of Daniell, are probably the best. With 36 Leclanché cells one ought to get a strength of 300 to 350 milliampères. If a rheostat is used, a much larger number of cells will be required, because the greater the resistance the greater must be the tension. This entails large extra expense and is really not necessary with the sulphate of copper battery.

The collector. This keyboard arrangement is invaluable; for, with one hand holding the electrode in place, the operator can at will bring into the circuit any number of couples desired; he can change the current at will, or can produce voltaic shocks.

The galvanometer. To measure the dosage exactly is an absolute prerequisite of success. The one of which I know most is that made by Gaiffé, and of which the recorded error is only 2 or 3 per cent. Apostoli gives the following records: *Edelmann's* galvanometer without "shunt" fails to the amount of 7.5 per cent.; with "shunt" the defect increases to 20 per cent. It registered $\frac{160}{1000}$ ampère, instead of $\frac{200}{1000}$ ampère. *Waite's* is equally unreliable. The constants are:

Without shunt .	error	6 per cent. at least.
With shunt	10–32	" " "
With shunt	100–25	" " "

The faradic battery. Duchenne, of Boulogne, pointed out the difference in action between the current of the first helix (extra current) and that of the second helix (the induced current). These points were disputed by Becquerel, who claimed that the physiological differences were due to physical differences, and that currents of the same *intensity*, *tension*, and *duration* produced the same effects. The current of the second helix, which is made of long, thin wire, will, of course, give a greater tension than that of the first helix, which is of short and thick wire. Onimus claims that, when the tension is the same, the extra current (first helix) operates more appreciably upon the sensibility of muscles and upon the excitability of certain organs. For the uses of the gynecologist, especially within the uterus, the induced current of high tension from the long, thin wire will be the one generally used. The little well-known portable battery of Gaiffé, with a chloride of silver pile, is excellent and answers every purpose. It has also the merit of being cheap. This consists of two elements contained in one partition of a small box of gutta percha. The vibrator can be entered or withdrawn by means of a handle. A

band of copper, elastic and connected with this, permits a just regulation of the currents. A graduated tube penetrates between the central barrier of soft iron and the inductive bobbin, so that by withdrawing it or pushing it in we get a greater or less intensity of current. Two interruptions per second, I have found, were tolerated without discomfort, but the pain increases with the number of the interruptions.

The therapeutics of the induced and of the continuous currents.—"The induced current penetrates the tissue profoundly by reason of its high tension, but, contrary to physical laws, the continuous current of low tension has a larger and more profound action. We have proved the diffusion of the electric currents, and that the galvanic current propels itself through organic tissues, its influence being felt at remote points; the current *never remains limited between the two poles.*" (Onimus.) "If we now consider the differences that exist between continuous and induced currents during their *constant* passage, we find that it is not difficult to distinguish between them, as the line of demarcation is clear. The induced current acts for an exceedingly short time during its passage. It produces at each instant of passage a greater or less excitation, and causes molecular shock. The induced current acts mechanically as an excitant, but the continuous current penetrates more gradually the tissues, but more profoundly, acting chemically in such a way as to produce molecular orientation and chemical combinations." (Onimus.)

The induced current traversing the liquid, semi-liquid, or solid substances that go to form the human body, produces no chemical action whatever—simply a mechanical molecular disturbance. The continuous current, however, not only produces its chemical action at the poles, but this molecular disintegration and orientation are propagated throughout the zone between the poles. This question has excited much discussion recently before the British Gynecological Society, and many letters have appeared in the pages of the *British Medical Journal* upon the same subject; Dr. Bantock and others who are opposed to the results of the Apostoli method, believing them to be grossly exaggerated, but who, also, it is easy to see, have given the subject but superficial study, claiming that the action of the galvanic currents was simply at the poles, that some little effect was produced in the uterine fibres, causing them to contract, and that this contraction might be the reason of the apparent diminution of the tumor; but in a most illogical way proceeded to argue that the continuous current passed through a fibroid removed from the body would have no effect whatever. They believed that tumors were never diminished or dissipated, etc.; all of which was mere argument, since the fact is as proven as any fact of record, that fibroids are diminished, and that the action of the current is not limited to the poles. When such men as Sir Spencer Wells, Keith (father and son), Rutherford, Simpson, and others, who have done as magnificent surgical work as any surgeon living; when Martin, Engelmann, and Woodham Webb, all state that they have diminished and even dissipated such tumors by this plan; when reports from Italy and Spain confirm the same, by detailing results equally good, and when we add to this the record of thirty others who have reported similar cases, all men of unimpeachable honor and highly esteemed in the profession, the puerility of the arguments cited becomes very apparent.

Just what the galvano-caustic action is that dissipates a tumor is not yet determined. Whether it coagulates the albuminoids, or creates interstitial inflammation, I do not know. It *does reduce the tumor*, and it remains for us to find out the *why*. I believe, however, that time will demonstrate a change of *cell-life* in addition to the purely chemical action which takes place around the poles. To quote it at length would consume overmuch time, but one may read with much profit Dr. Apostoli's paper, which was read at the British Medical Association, at the Glasgow meeting, August, 1888, on "Some Novelties in my Electrical Treatment of Uterine Fibroids, with Answers to Objections." In his clinic in Paris the induced current is not often used. It has a wondrous effect, however, upon the ovarian pain in hysterical women. Both the + and the — poles are carried to the fundus through an insulated sound, at the base of which is a square cap for the attachment of the wires. I have seen now twenty cases of this kind, and every woman received immediate benefit after a séance of ten or fifteen minutes

Uterine fibroids.—In no clinic upon the continent have I had such large opportunities for studying and examining uterine fibroids. The number of women is always large, presenting every variety of shape, position and size of tumor. Each case is regularly entered upon the record book, together with exact measurements of the tumor and the diagnosis, all of which may be confirmed by the medical gentlemen present. If the case is one of unusual interest, a plaster cast is made of the woman's abdomen. After each treatment the measurements are again taken and noted. The record of each case is open to the free investigation of anyone, and anyone may question the patients, examine or measure them. Everything done here is frank, honest, and above-board. There is no secret about it—statistics are not garbled, or manufactured to defend a theory. I have seen a large number of bleeding fibroids—some very bad, indeed—but I have yet to see my first case that failed to respond immediately to the continuous current, the positive pole being within the uterus. The strength of the current will vary with the amount of resistance and tolerance, some women bear large doses without inconvenience. I have seen Apostoli carry the current quite often up to 350 milliampères without any discomfort to the

patient. If the tumor be hard, and if the plate on the abdomen be large and fit snugly, I can see no reason why a current could not be increased to 500 milliampères or more without risk, though such an amount can rarely be demanded.

In arresting a hemorrhage it is most important that every part of the lining membrane of the uterus should be treated—and that the bulbous-pointed electrode should be large enough to fit tightly, so as to embrace all surfaces. No hemorrhage, however severe it may be, will resist this treatment if rightly carried out. Now I would put the question squarely and fairly: If Tait's operation, so called, was devised solely for the purpose of arresting the hemorrhage of a bleeding fibroid, and if this operation is attended with danger, is it not immeasurably better to resort to a method which is unattended with any risk of life, which is immediate, and which entails no mutilation?

The records of Apostoli's method are quite as reliable as those of any laparotomist, and I have not seen or heard of a case of failure. I remember the case of Mme. Richard, and so will the many gentlemen who worked with me at Apostoli's clinic. She had a large bleeding fibroid; had to be carried up stairs; weak, feeble, and blanched. Two applications arrested the hemorrhage entirely, and now under continued application the tumor shows signs of diminution. Two other cases come to me now, one sent by Dr. Péan and the other by Dr. Labbé, both cured of the hemorrhage, and in each the tumor is diminishing. The assistant of Dr. Simpson, Dr. Wright; the assistant of Dr. Slavanjsky, of St. Petersburg, Dr. Massin; Dr. Matos, of Barcelona; Dr. Hall, of Baltimore; Dr. Hobart, of Boston; Dr. Smith, of the U. S. Navy, all of them watched these cases with me. We will go a step farther. The continuous current will arrest the hemorrhage. I affirm also that it will very appreciably diminish the size of the tumor.

A very notable case is that of Mme. Lejeune, who had a large, lobulated fibroid, reaching two fingers' breadth above the umbilicus, and reaching down in the iliac fossa of the left side. She was the directress of a large public school, but for some time was unable to attend to her duties. After five *galvano-punctures* she resumed her duties, and the tumor can be well limited now to a distance midway between the symphysis pubis and the umbilicus. It is also much softer. In six other women the reduction of size is most considerable, and in one the tumor is only barely perceptible. Plaster casts of these women are to be seen at the clinic.

The punctures are made with a lance-pointed steel needle, with a penetrating depth of 1-3 centimetres, the *negative* galvano-caustic being usually resorted to. The needle is insulated in a rubber tube, up to the exact point of penetration. The insulator is pressed against the most prominent point of the tumor, which is usually in the lateral fornix, and the needle is plunged in—being careful to avoid a pulsating surface. Everything is rigorously antiseptic. The bed of potter's clay, being very pliable, adapts itself readily to the irregularities of the abdominal surface. The strength of the current used is from 100 to 300 milliampères. Many of these women who at the beginning of the treatment were almost bed-ridden, are now pursuing their usual avocations, and not one of them has ever had a bad symptom. Granting then, as needs we must, that the records in these reported cases are quite as reliable and trustworthy as are those of any surgeon, I again ask, Why perform the operation of Mr. Tait, which has for an ultimate object reduction of size of the tumor, by setting up the menopause, if electricity will produce the result more speedily, more safely, more surely, and to a more considerable extent?

Dr. Rutherford reports a case in which the tumor entirely disappeared under the plan of Apostoli, and Mr. Webb, of London, told me that he knew of a similar instance. All of us here, who attend the clinic, have seen a case in which the tumor is with difficulty made out. I ask again, Should the case be a suitable one for this method, why resort to the dangerous operation of laparotomy until electricity has been given a fair trial by competent persons? Apostoli's method arrests hemorrhage, diminishes size, relieves pain, and improves nutrition, without endangering life. Is there anything known to surgery which can offer as much?

Catarrhal salpingitis yields kindly to the simple action of the continuous current—one pole in the uterus. Pyo-salpingitis is more stubborn, and I am not ready to offer any decided opinion quite yet. I have seen Dr. Apostoli puncture (negative) the tube, then enlarge the incision and insert a drainage tube, in a woman bed-ridden with a specific purulent salpingitis. She is now performing her duties comfortably, but there is considerable discharge. In another case, one galvano-puncture relieved the woman to such an extent that she confesses to being well, and there is no abnormal feel of the tube either by vaginal or rectal touch. There is a large field here for study—a profitable one too. In the French Academy of Medicine they are discussing methods of drainage by uterus and vagina, without the necessity of operating, so that the minds of the surgeons themselves are turned in conservative directions. I am sure that the time is in the near future when electricity shall solve the riddle.

Metritis.—In an interesting monograph on this subject, under the caption: "On a New Treatment of Chronic Metritis," by Dr. Apostoli (translated by Dr. A. Lapthorn Smith), it is written:

"In the presence of a metritis of an anatomical form only slightly characteristic, when we are in doubt, and

when there is reason to ask ourselves the question whether the case is suitable for faradization or chemical galvano-cauterization, this is the practical and clinical means of deciding the question: We should try first faradization; if it is well borne from the beginning, on an average after the third or fourth application we should have obtained either marked relief, which would induce us to continue the same treatment—or a failure, in which case intra-uterine galvano-cauterization would be required. On the other hand, an improvement, even very marked at the outset, may wear itself out very soon, as it frequently does, and there again faradization must be replaced by galvano-cauterizations."

Dr. Apostoli concludes as follows:

"In establishing the therapeutical limits of the induced or faradic current, applied according to my double or bi-polar method: it is an excellent and sometimes sovereign remedy in certain cases (recent subinvolution, chronic metritis in the first stage); inefficacious, or at least very insufficient in others (such as chronic metritis in its later stages), and endometritis in any form."

I should like to commend this little book to the earnest study of all those interested in this subject, because it deals fully with all the methods, and in the appendix gives much valuable information as to the faradization of the uterus after labor, as well as to the use of the continuous current in fibroid tumors. It covers much ground within a small space. I have not yet treated, neither have I seen treated, a case of metritis after this method.

Endometritis.—I have seen a large number of these cases benefited by the continuous current, the positive pole being within the uterus. I have the records of four women who suffered from a fungoid condition of the endometrium, and in all of whom the benefit was marked. One girl, with weak eyes and coxalgia, with a specific endometritis and a not clearly defined salpingitis, grew better rapidly, but after each séance had quite sharp attacks of nausea and nervousness. In all forms of ulceration or hemorrhage the positive pole is indicated. This pole leaves a *white* scar, while the negative pole gives a deep *violet* scar. The positive pole is coagulating or hemostatic, and is the one around which the acids collect. Apostoli claims its action to be twofold: First, it arrests the hemorrhage; and secondly, owing to the retractibility of the positive cicatrices and to the greater or less atresia which follows it, a return of the hemorrhage later on is guarded against.

Peri-uterine inflammation.—Dr. Apostoli faradizes every woman, even when under an acute attack of inflammation, observing the following conditions:

"*a.* I proscribe every faradization that would cause the least pain, and expressly that of quantity, engendered by the bobbin with short and thick wire.

"*b.* I use for such cases the bobbin with long and thin wire, from which I obtain a current of tension on account of its specially anodyne effects.

"*c.* I begin with a simple vaginal application, by means of a large bi-polar electrode, the point of which is placed against the inflamed part.

"*d.* I only employ a current easily bearable, so as to cause no suffering nor any excitement to the patient, as this would insure an entire failure of the treatment.

"*e.* All the success of this medication depends upon making the first sittings sedative, so that they may serve as a prelude to more active measures; and the faradization will only become hyposthenic on the double condition of its low intensity and its long duration.

"*f.* Each sitting should last 5, 10, 15, 20, or 25 minutes, as may be required, and should not terminate before the patient spontaneously declares that she is better and suffers less.

"*g.* It is necessary to reinforce what has been said by dogmatically averring that no success will come out of this treatment unless it be managed not only without violence, but with extreme gentleness.

"*h.* There may be one or two sittings each day, as may be wanted, for lowering the febrile action, allaying pain, and bringing about what is called the subacute stage of the disease.

"*j.* Every faradization should be preceded and followed by a vaginal irrigation with the sublimate solution, and all of the sounds should be scrupulously disinfected."

In the *subacute* stage, use first bi-uterine faradization, with a current of tension; when the inflammation begins to give way, we use the intra-uterine *continuous* current, beginning first with the *positive pole* and following with the negative so soon as we are sure that the patient can bear it.

In the *chronic stage*, Apostoli uses with great success the continuous current and galvano-puncture (negative), making the puncture in the diseased part itself. In old cases of perimetritis, with much tenderness around the utero-sacral ligaments—cases which are very common and stubborn—much relief may be obtained by pressing the large bulbous vaginal electrode well up into the posterior fornix, while the negative pole is on the abdomen, using the induced current of high tension.

It were much easier to write a book upon these subjects than to outline them in mere profile, because, naturally enough, many points will come up for discussion which are not here discussed for want of time. Apostoli has gone into the whole matter very thoroughly in his numerous contributions to medical literature. They are easy of access, and I commend them to the earnest attention of those who have knotty points to be solved.

PARIS, January, 1889.

A CASE OF ACUTE YELLOW ATROPHY OF THE LIVER.

BY MARTIN W. BARR, M.D.,

RESIDENT PHYSICIAN AT PENNA. INSTITUTION FOR FEEBLE-MINDED CHILDREN, ELWYN.

I THINK in the practice of every conscientious physician there comes a time, while attending a case of desperate illness, when, after he has given one remedy, he regrets that he has not given some other: when he searches his books for assistance and is confronted by long lists of drugs, one seemingly as efficacious as another. But he gets nothing definite. Then how gladly would he appreciate

some specific information—some report of a similar case—no matter how crude or meagre it might be. For this reason I have tried to describe my case accurately, and have written out some of the prescriptions used.

It will be noticed that my treatment was extremely simple. I consider the nitro-hydrochloric acid dilute was my sheet-anchor. I used it for two reasons: for the reported action of both nitric and hydrochloric acids on the liver, and because I obtained such excellent results from the combination during an epidemic of typhoid fever some years ago. Probably any one of the mineral acids might act as happily.

The first authentic record of this disease was made by Morgagni,[1] who considered it extremely dangerous and difficult to cure. His opinion is endorsed by Graves, Frerichs, Rokitansky, Tanner, Buhl, Hilton Fagge, Grainger Stewart, Ozonam, Legg, Liebermeister, Harley, Oppolzer, Bright, Horaczek, Wagner, Späth, Von Dusch, Guckelberger, and Bartholow—besides many other well-known writers on hepatology.

Hanlon reports three cases in one family in one year, one of whom recovered. Griffin reports four cases in one house occurring within a short time of each other, two of whom recovered.

On November 2, 1888, I was hastily summoned to see Rissie R., a girl aged twelve years, residing in Cecil County, Md. The messenger briefly stated that she had had a congestive chill on the previous day, and was then suffering from a second. I will here mention that the autumn had been warm and rather dry, with but little frost, and her home was in a malarious district. Family history was good, ancestors on both sides having been for generations sturdy, healthy farmers, who had, for the most part, died of old age.

Rissie had never been a very robust child, and she had been troubled with chills since September. Her mother, without consulting a physician, dosed her freely with quinine, and, with her ears still ringing with the drug, she would have chill after chill.

It was almost two hours after my summons before I reached the patient, and the chill had passed off, leaving her much exhausted. She was a perfect blonde, with a fair complexion, light hair, and blue eyes. I found her slightly jaundiced, tongue heavily coated, breath fetid; pulse strong and rapid; temperature 103°. Prescribed ℈j quiniæ sulph. in solution, to be taken every four hours for twenty-four hours. I charged the system so heavily with this drug in order to prevent any possible recurrence of a third congestive chill.

3d. At my second visit I found my patient decidedly worse. There had been no chill, but the jaundice had become most intense. She was as yellow as if she had been dyed with saffron, the color of the conjunctiva being especially brilliant. Even the lips and gums had assumed a bright salmon color. The teeth were covered with brownish sordes, slightly tinged with green. The tongue was heavily coated, the fur being a bright grass green. Late the previous night distressing spells of vomiting had come on. The emesis was green, and was always preceded by a period of extreme nausea and retching. These periods became more and more frequent until they occurred every ten minutes, or oftener. Between each vomiting spell the child would lie with closed eyes in a lethargic state, only rousing occasionally to ask for ice. The urine was dark-colored and scanty. Pulse 124; temperature 104°. Extreme tenderness in epigastric and right hypochondriac regions; the slightest touch being sufficient to elicit cries of pain from the patient. On percussion I could distinguish marked diminution in size of liver, but could detect no increase in size of spleen. I then made a positive diagnosis of what I had before suspected—acute yellow atrophy of the liver.

I immediately prescribed acidi nitro-hydrochloric. dil. ♏v, every three hours, in water. I continued this drug (though less frequently in the later stages of the disease) uninterruptedly night and day until convalescence.

For the nausea and vomiting I gave the following prescription:

℞.—Bismuth. subnit. . . . . ℥ij.
Acidi carbolic. . . . . gr. iv.
Aquæ menth. pip. . . . . f℥vj.
Aquæ q. s., ad . . . . f℥iij.—M.
Sig.—Teaspoonful in water every two hours.

Had a large, strong mustard plaster placed over the hepatic region.

I ordered as much milk, combined with lime-water, as the patient could be induced to take. Also brandy and ice *ad libitum*.

4th. Patient passed a bad night. Nausea and vomiting continued unabated. Some petechiæ on right side of trunk—but not very marked. Considerable pain on micturition.

5th. Patient passed another wretched night. Nausea and vomiting still present—if anything, slightly more intense than before. Vomit had become chocolate-colored and bloody. Milk was regurgitated in large curds almost as soon as swallowed. Retention of urine and constipation. Intense pain over whole abdomen. Discontinued bismuth and carbolic acid mixture. Prescribed minute doses of calomel 1–10 gr. every hour. Gave a hypodermatic injection (morphinæ sulphas, 1–6 gr., atropinæ sulphas, 1–180 gr.) in abdomen.

For the retention of urine I prescribed the following:

℞.—Fld. ext. hyoscyamus . . gtt. xxx.
Sodæ bicarb. . . . . gr. xxxviij.
Aquæ q. s., ad . . . . f℥j.—M.
Sig.—Teaspoonful in cold water every three hours until patient micturates.

I ordered a rectal injection of hot water, castile soap, and glycerine. The patient had a copious dark-colored passage containing a great deal of blood. She fainted shortly after the injection, and

[1] De sedibus et causis morborum, Epist. x., 7, et Epist. xxxvii., 2, 4.

remained unconscious for some time. Was massaged briskly and revived. I allowed the mother, at her earnest request, to apply various poultices, spice plasters, etc., to the hepatic region.

6th. Found my patient somewhat better, but extremely weak. She passed a comparatively quiet night; the periods of nausea and vomiting were lessened in frequency and duration. After taking several doses of the hyoscyamus mixture the patient micturated freely. Had bowels moved by enema; stools dark and tarry.

7th. Jaundice had begun to fade. Nausea and vomiting lessened perceptibly. Pain in abdomen had returned in all its intensity. Administered another hypodermatic injection. No movement from bowels. Prescribed aloin 1-5 gr. three times a day.

8th. Was much improved. Had emerged from lethargic state and asked for chicken. The vomiting had ceased entirely, but occasionally she would have slight attacks of nausea. Jaundice was fast disappearing, also the petechiæ. Had had a dark passage early in the morning containing but little blood. The temperature, which had continued high during the whole of the attack, had now sunk to normal.

From this time on, the patient began steadily to improve. The jaundice faded rapidly, and the liver almost regained its normal size. I continued the dilute nitro-hydrochloric acid in five gtt. doses every four hours from November 8th to the 16th. From 16th to 25th, gave it three times a day. By this time the patient was practically well. Stopped the acid and ordered tinct. cinchon. comp. and a plain wholesome diet.

I did not see her again, but, on December 24th, met parents, and they told me she was in better physical condition than she had been for years.

THE TREATMENT OF CLUB-FOOT.[1]

By THOMAS GEORGE MORTON, M.D.,
SURGEON TO THE PENNSYLVANIA HOSPITAL.

I HAVE recently had under care a number of cases of club-foot which I have treated by combinations of tenotomy, the open incision, and tarsectomy. In four cases both feet were involved. In one case the deformity was a severe equino-valgus, all the other cases were types of severe equino-varus, in which the patients walked upon the dorsi of the feet. Two cases were females; the youngest patient was four years of age, the oldest eighteen; all made excellent recoveries. Two of this series of operations were performed by Dr. T. S. K. Morton.

The proper time to treat most successfully talipes is at birth, when the infant foot readily yields to stretching and manipulation; although infantile varus can always be overcome, more or less equinus may persist and eventually require division of the tendo Achillis, but this operation should not be considered until the child is ready to walk.

Without any treatment deformities of the feet rapidly increase, the tissues become unyielding and the child eventually walks upon the dorsum of the foot, while the change which subsequently takes place in the tarsus practically precludes complete and satisfactory correction without an excision of a wedge, open incision on the inner side of the foot, and tenotomy.

The following cases illustrate this class of deformities:

CASE I. *Double equino-varus.* — James B., æt. sixteen, congenital double talipes equino-varus. Has never been operated upon. Legs are very poorly developed and he walks upon the dorsi of the feet.

October 9. I tenotomized all resisting structures in the left (his best) foot, broke it as well into position as possible, and placed it in position on a right-angle tin splint.

Result not very favorable.

31st. I excised the cuboid bone from the right foot and was thereby enabled to bring it into excellent position. Primary union of wound. Result perfect.

December 2. Left cuboid excised by Dr. Thomas S. K. Morton and foot brought into position. Primary union in this wound also. Result perfect. For some months he wore braces but then abandoned them, since which time he has worn ordinary shoes. With shoes on, no one could tell that he had ever had talipes, and scarcely could one believe upon looking at his bare feet what they had been before operation.

CASE II. *Equino-varus and equino-valgus*—I. S., aged eighteen, severe congenital equino-varus of the right foot, and equino-valgus of the left; both limbs poorly developed. I divided all the tendons concerned in the deformity, then being unable to bring the foot into a good position I excised a wedge of the tarsus, the base included the cuboid, the external and middle cuneiform and part of the scaphoid. Primary union and a perfect result followed.

Two months later, after tenotomy of the peronei and tendo Achillis, I removed a wedge from the inner side of the right foot to overcome the equino-valgus. The wedge included the scaphoid, and part of the internal, middle, and external cuneiform bones.

The result was entirely satisfactory; primary union followed the operation. Patient finally acquired perfectly useful and even very presentable feet.

CASE III. *Equino-varus.*—Miss X., æt. nineteen, had been operated upon in Germany when an infant. But one foot is involved; that presents a marked equino-varus with great deformity. July, 1888, Dr. T. S. K. Morton excised a wedge of tarsus of sufficient size to permit bringing the foot to a normal position. Catgut drains were used and primary union was secured. Placed in position upon right-angle tin splint and not dressed for three weeks after operation; foot then in excellent position. Oct. 1888:

[1] Read before the Philadelphia Academy of Surgery, May 6, 1889.

She is now able to wear an ordinary shoe and to walk without limp or discomfort. Result perfect.

CASE IV. *Equino-varus.*—In November last I made a tarsectomy of the left tarsus for equino-varus upon a girl of five years of age. She was one of six children, four of whom had been born with club-foot; one boy had double equino-varus; three girls had similar deformity, but confined to one foot. The parents were very robust people, and no other cases of deformity had been known in either family. I removed a wedge of the tarsus and divided all tense tendons, including the tendo Achillis, the posterior tibial, and the long flexor of the great toe. Result, as in all cases upon which I have operated in this manner, absolutely perfect, and her brace is about to be discarded for an ordinary shoe.

CASE V. *Double equino-varus.*—C. K., aged four years. No family history of talipes. Two other children free from deformity. Feb. 13: Excised wedge from left foot; usual technique. Dressed at end of three weeks; primary union; excellent position. March 21: Excision of wedge from right tarsus combined with extensive tenotomy and open incision of inner aspect of foot. Not dressed until end of fourth week. Solid union by primary intent and faultless position found.

This case is still wearing light supports, and is daily receiving massage and electricity—as, indeed, is ordered for all my cases, both before and, as soon as permissible, after operation.

CASE VI. *Double equino-varus.*—J. C., æt. four. Excision of wedge of right tarsus combined with tenotomy. Dressed in three weeks. Six weeks after first operation a wedge was likewise taken from the left tarsus and open incision made upon the inner side of the foot. Both feet perfectly restored in shape and utility.

CASE VII. *Severe equino-varus of right foot.*—Mary ——, aged twelve. Excision of usual wedge and tenotomy performed. Operation done three weeks since. Wound healed and result promises to equal in success all the others which I have performed.

The treatment of the muscles of a limb after club-foot operations is of very great importance. Congenital club-foot is the result of nerve changes, or, in other words, a sequence of intra-uterine paralysis, so that it is eminently proper that treatment after the correction of the deformity should be directed to the improvement of the nutrition of the limb. Therefore, massage, electricity, and douchings should be employed persistently for a long time subsequent to operation. In hospital dispensary work especially it is difficult to impress upon parents the absolute necessity for the long continuation of treatment after operative interference. It is usual to find the entire limb in a club-foot case less developed, the calf and thigh measurements show more or less atrophy, while in the length of the limb the difference is often very marked when compared with the normal extremity.

One important advantage gained in the treatment of club-foot by excision of a wedge from the tarsus is, that in at once correcting the deformity we avoid the necessity for the protracted use of steel braces, which are often heavy and clumsy, and which hinder the growth of the limb. If by a radical operation we can in a very short time overcome the deformity and also the tendency to recurrence and allow the child soon to wear an ordinary shoe, we most favor the development of the affected limb.

In operating for equino-varus I first section all resisting soft structures, then, if the foot cannot be brought to and held easily in a normal position, I make an incision on the outer side of the tarsus and remove a wedge with its base looking outward from the tarsal bones considered as a whole. In making this excision it is of the greatest importance that a sufficient amount of bone is removed: the apex of the wedge should come to a point almost or quite to the opposite side of the tarsus. With me the wedge will usually comprise: the anterior three-fourths of the cuboid, the whole of the external and middle cuneiform, with perhaps a shaving also from the anterior portion of the scaphoid, and the heads of the two outer metatarsal bones. If, when this much has been done, the foot does not come around to its normal position without the least resistance, I further remove the internal cuneiform, and, if also required, dissect out the remaining portion of the cuboid. For excising the wedge I employ ordinary cutting pliers in preference to the chisel, owing to the inevitable disadvantages incident to the bruising caused by the latter instrument, and because, in my hands, the cutting pliers have proved so much more accurate, easy of manipulation, and expeditious.

A HITHERTO UNDESCRIBED CAUSE FOR THE FAILURE OF THE RADICAL CURE OF HYDROCELE BY INJECTION.[1]

BY CHARLES B. NANCREDE, M.D.,
SURGEON TO THE EPISCOPAL HOSPITAL, PHILADELPHIA.

IT hardly needs an apology for recording what appears to be a new pathological fact, yet the radical cure of hydrocele is usually so readily effected by the methods now in vogue that a paper on such a subject seems out of place. From the very frequency of the disease and the ease with which a cure is effected, the surgeon too commonly views it as a trivial affection and unhesitatingly promises a cure by the injection of iodine or carbolic acid, unless certain well-known contraindications exist, such as thickening of the sac, rigidity of its walls from calcareous deposits, etc. But despite the absence of these complications there are a certain number of cases where the confidently expressed

[1] Read before the Philadelphia Academy of Surgery, May 6, 1889.

opinion of the surgeon is *not* verified by the result, for the patient is either not benefited at all, or the case relapses in a short time, damaging the surgeon's reputation and shaking his confidence in a thoroughly reliable and safe remedy, provided the condition I propose describing be not present. Although Mr. Curling mentions one case where a "loose cartilage" was evacuated by incision, and states that certain methods of treatment are applicable in the absence of these bodies, he makes no mention of the condition I have observed, nor does he suggest the possibility that the cartilages which he so vaguely mentions may stand in a causative relation to relapses after the operation for a radical cure by the injection of iodine.

Anatomists have described under the name of hydatids of Morgagni certain fringed or pedunculated bodies situated at or about the junction of the epididymis and testicle. These probably at times contain cartilage cells, which, doubtless, when accidentally detached, form the "loose cartilages" so commonly referred to by writers as an obstacle to the radical cure of hydrocele by injection, but which are so rarely detected in practice now-a-days —in fact, I think, judging from an extensive search through the literature of the subject, that most authors have copied the statements of their predecessors.

Whether containing cartilage cells or not, it is evident from the two cases which I report, that these fringes may have calcareous matter deposited in or upon them, although the remainder of the serous sac may not be even thickened, and that the constant mechanical friction will originate and certainly keep up disease after an attempted radical cure by injection, until removed, or we have resorted to such measures as will produce total obliteration of the sac—which, it is well known, the method by injection often fails to do.

Both patients suffered much pain—an unusual symptom in hydrocele; both had recurrence after a radical operation by injection had been attempted, but it will be noticed that the effusion was located chiefly at the upper portion of the cavity, the testicle lying below, contrary to rule.

This was so marked in the first case which I saw for Dr. Barton, during his absence from the city, that I considered it to be probably an encysted hydrocele of the testicle or of the cord. It is a fair inference, then, that the injection had so altered the serous membrane that its secreting and absorbing power had again become normal—for there were no adhesions, except in the immediate neighborhood of the constant source of mechanical irritation. This is all the more probable, since one patient stated that the size of the swelling varied. Probably such concretions as well as loose cartilages are more common than is supposed, because few modern surgeons incise or excise the tunica vaginalis testis.

Before briefly reporting two cases, I would suggest the propriety, since antiseptic methods have lessened the dangers of the cutting operation, that when failure occurs after injection, even where no thickening of the sac—calcareous or otherwise—is detectable, an incision at least large enough to admit the finger should be made, the cavity explored for calcareous concretions, etc., and a large drainage tube passed through another puncture seton-wise, a practice successfully revived, I think, by my colleague, Dr. Barton—full antiseptic precautions being of course taken.

As this paper is merely a report of cases observed, with practical points suggested by them, no attempt will be made to consider exhaustively the operative surgery of this disease.

By Dr. Barton's kindness I have been furnished with the following notes of the case upon which he operated in my presence, and which first called my attention to this peculiar pathological condition.

Case I.—The patient, Mr. L., of South Carolina, had suffered three years with great pain in his testicles—especially the right one. This pain was only felt when he did not support the testicles. When sitting down with the testicles resting upon his legs he was entirely free from pain; but as soon as he stood up he suffered intensely, and was obliged to support the scrotum with his hand. His usual method of progression was with one hand in his pocket supporting the scrotum. His infirmity compelled him to confine himself to his store and to his boarding-house. His expressions of pain, his nervousness, and his mental excitement were such as to lead one to suppose that he was the victim of some mental trouble. Both testicles were enlarged and tender—particularly the right one. In the right tunica vaginalis, there was a small hydrocele, containing about one or two ounces of fluid, situated at the upper part of the vaginal sac. He had consulted a number of physicians and the hydrocele had been operated on twice—once by injection of iodine—but without benefit.

Under ether and with antiseptic precautions I opened the tunica vaginalis, liberated the fluid and explored the cavity with the finger. Directly beneath the testicle a bony mass about the size, shape, and hardness of a shrivelled grain of corn was found. Its attachments were so slight that it came away without effort and without our being able to say if it was attached to the visceral or parietal layer of the vaginal tunic. No further growths were found. A drainage tube was introduced, antiseptic dressings were applied, and he recovered without accident. Before going home he was able to walk about the city, which he did morning, noon, and night, taking more exercise of this kind in a few days than he had done in several years previously. He had no pain, though the testicle was still slightly tender on pressure.

CASE II.—My patient was an elderly man who had suffered with a moderate sized, very painful hydrocele for an indeterminate time. In April, 1888, Dr. Simes operated for the radical cure by the injection of carbolic acid. Severe inflammation followed, producing extensive sloughing of the scrotum and presumably of a portion of the vaginal tunic. When seen over a month later, the hydrocele seemed cured. Some time during the next six months—for I could get no very definite statement from him—the disease recurred, with the old symptoms of constant pain on movement. On coming under my care on April 1st, he showed me a small hydrocele, closely resembling in situation and appearance that first described.

Taught by the case seen with Dr. Barton, I opened the swelling by a free incision and considerably to my astonishment, at the junction of the upper part of the epididymis with the body of the testicle, I felt a little calcareous body like a miniature cock's-comb. I removed this with the finger, dissected out a portion of the tunica vaginalis, and, partially suturing the tunica and skin, drained the sac-cavity. Antiseptic methods carried my patient through with no untoward accidents, and at the last reports he was well and free from all his former suffering.

MEDICAL PROGRESS.

Survival after Wounds of the Heart.—DR. ANDREA CRISTIANI, Assistant to the Professor of Forensic Medicine in the University of Pisa, has lately recorded[1] a remarkable case, in which a man lived thirty-nine days after having received an incised wound of the heart. On April 22, 1888, a man, aged about twenty-five, was stabbed in several places in a brawl. One of the wounds was in the fifth interspace on the left side, about the situation of the anterior axillary line; there was a second in the eighth interspace on the same side, and another in the back on the left side, extending from the posterior border of the axilla toward the scapula. Besides these injuries, there was a stab in the left hip, and several others on the right arm. The wound first inflicted was the one in the back, the second that in the cardiac region, after receiving which the man fell to the ground, but was still able to recognize the assailants who dealt him the subsequent blows. He was carried home, and, when seen by a medical man an hour and a half later, was able to give an account of the affair. Though he lost an enormous amount of blood he did not faint, but complained of dyspnœa. The respirations numbered fifty in the minute; this lasted eight or ten days. There was slight pyrexia for twelve days, but beyond the fact that the least effort caused breathlessness and palpitation, there were apparently no particular symptoms. The wound in the fifth interspace cicatrized in seven, and that in the eighth interspace in eight days, while the one in the back took fifteen days to heal.

On the eighteenth day the patient got up, though still very weak and anæmic. On May 29th he complained of not feeling well, but in spite of this he walked into Pisa and back, a distance of ten kilometres (about six miles and a quarter) in the morning, and in the afternoon walked to a neighboring village, three kilometres (nearly two miles) from his home, with two companions. On the way back he climbed a tree in order to get a bird's nest, and on coming down fell to the ground and died in ten minutes. The necropsy showed that the stab in the fifth interspace had traversed the pericardium, and deeply wounded the wall of the left ventricle, at a distance of three and a half centimetres from the apex, without actually penetrating into the cavity. Between the edges of the wound was some soft coagulum, on removing which it was found that the deeper parts were pretty firmly united by organized blood-clot. This cicatricial tissue had quite recently given way at one spot, where there was a small opening leading into the cavity of the ventricle. The effort of climbing the tree, after the relatively severe exertion previously undergone, had burst open the partly closed wound, and broken down the frail barrier which was left between the ventricular cavity and the outside of the heart.

Dr. Cristiani attributes the long survival of the patient to the oblique course of the wound through the layers of the ventricular wall, and to the fact that the knife did not actually penetrate the cavity. The excellence of the patient's general health must also be taken into account, as owing to that there were no inflammatory complications either in the heart, the pericardium, the lungs, or the pleura. On the medical evidence the assailants were condemned to two years' imprisonment for attempted homicide.

To Dr. Cristiani's report is appended a note by DR. VITTORIO MESSERI, of Florence, relating the case of a man, aged thirty, who, on March 16, 1884, was stabbed with a thin-bladed knife in the fourth interspace one finger's breadth to the left of the sternum. He was admitted into the Hospital di Santa Maria della Consolazione at Rome, apparently in a moribund state. After some hours, however, the pulse became perceptible, and the heart sounds (both replaced by blowing murmurs) became audible. The external wound quickly healed, and the patient made such progress that he got up on the tenth day. On April 6th he felt so well that he asked to be discharged. On this being refused he flew into a passion, and walked quickly into the garden, where cyanosis with intense dyspnœa suddenly came on, and he died almost immediately. A large amount of blood was found in the pericardium and in the left pleural cavity. There was a wound of the right ventricle close to the interventricular sulcus, and a wound of the septum near its anterior margin. The former had healed, and the cicatrix had recently broken down, while the latter, on microscopic examination by Professor Marchiafava, was found to be surrounded by granulation tissue, which had transformed it into a kind of fistula.

Dr. Messeri refers to statistics collected by Professor Zanetti, from which it appears that among one hundred and fifty-nine cases of wound of the heart, in only ten was the septum perforated. In seven of these death was instantaneous, in one it took place in an hour and a quarter, in another in two hours, while in the remaining case the patient lived twenty days. — *British Medical Journal*, April 27, 1889.

The Use of Sublimate in Obstetrics.—Many practitioners of late have abstained from using sublimate of mercury in

[1] Lo Sperimentale, March, 1889, p. 245, et seq.

obstetrics owing to its poisonous character. DR. WINTERNITZ, of Tübingen, has conclusively proved by a long series of experiments, that the drug when used in solutions of 1 : 2000 has no poisonous effect whatever. He has, however, always taken certain precautions in its use. The back of the patient should be raised in order to facilitate the immediate flowing out of the solution after its injection. Great care should be taken that none of the solution enters the womb. Dr. Winternitz has used sublimate in 1644 births without ever having observed any symptoms of poisoning.—*Deutsche med. Wochenschr.*, April 18, 1889.

Transmission of Pneumonia in Pregnancy.—DR. NETTER lately brought to the notice of the Société de Biologie a case confirming the possibility of the transmission of an infectious malady from the mother to the fœtus in utero. A woman pregnant seven months and a half was admitted into the Hospital Beaujon for pneumonia of the apex of the right lung. The disease evolved regularly, and on the seventh day defervescence was produced. Two days after the fall of the body temperature the patient was delivered of a child that lived five days. At the necropsy there was found distinct pneumonia of the right upper lobe accompanying fibrinous pleurisy, pericarditis, suppurating cerebro-spinal meningitis, and otitis. Bacteriological examination demonstrated the presence of pneumococci in the lung and in the blood. It was, therefore, concluded that this pneumonia was clearly hereditary and not acquired, and that it had been transmitted by the mother to the fœtus. Moreover, Dr. Netter demonstrated by experimental proof this pneumonic transmission. A guinea-pig, whilst pregnant, was inoculated with a culture of pneumococci; these microörganisms were found in the fœtus.—*Lancet*, April 20, 1889.

Pastilles for Disinfection.—The *Rundschau für Pharmacie*, April, 1889, gives the following:

℞.—Paraffin	9½	parts.
Iodine	1	part.
Salicylic acid	2	parts.—M.

This mixture made into pastilles produces iodine and carbolic acid when burnt, and will both deodorize and disinfect the sick-room.

On Tubercle Bacilli.—PROF. KREMIANSKI, of Kharkoff, whose name is known in connection with the so-called aniline treatment of phthisis, has just published, in conjunction with Dr. Tseslinski, an article in the *Meditsinskoë Obozrénic*, on the importance of frequent microscopical examination of the sputum both for diagnostic and for therapeutic purposes, in cases where phthisis is or may be present. The patients examined amounted to 931, and they were most of them seen in Prof. Kremianski's polyclinic or out-patient department, something like 10,000 microscopical observations having been made during the course of the last two years. In addition, very thorough physical examinations were carried out, not merely by means of the stethoscope, but with the help of the spirometer, manometer, thoracometer, thermometer, and weighing machine. As far as possible, also, very complete notes were taken of the effects of different remedies.

Of the 931 cases, tubercle bacilli were found in 570, or in 61 per cent., including cases of the most diverse description, some having cavities, some apex consolidation, and some merely signs of bronchitis or bronchopleuritis. Thus, of the 570 cases presenting bacilli, 220, or 38 per cent., had cavities; 229, or 40 per cent., had apex consolidation; 19, or 3 per cent., had simple "bronchitis;" and 5, or 0.8 per cent., had "bronchopleuritis." A considerable number (97) of the cases were sent by medical men to have the sputum examined for the purpose of diagnosis. It was by no means uncommon to find a complete absence of bacilli in the sputum of patients presenting the clearest physical signs of phthisis—consolidation, and even cavities. Of 238 patients with cavities, bacilli were absent in 18, or in 7 per cent. Of 419 cases of consolidation, bacilli were absent in 190, or in 45 per cent. Of 54 cases of "bronchitis," they were absent in only 35, or in 65 per cent. Bacilli were never found in cases of uncomplicated emphysema—*i. e.*, where there were no cavities or consolidation in addition.

With regard to Prof. Kremianski's special method of treatment, while it was only successful in entirely arresting the development of bacilli in about 30 cases, it produced a cessation of the ordinary symptoms of phthisis—cough, debility, fever, sweats, etc.—in about 300 cases.—*Lancet*, April 27, 1889.

Cornutin in Obstetrics and Gynecology.—DR. H. THOMSON reports in the *Centbl. f. Gynäk.*, No. 11, some results obtained with cornutin at the Clinic of Professor Küstner at Dorpat. According to Dr. Kobert, the remedy was administered either subcutaneously, in the following formula:

℞.—Cornutin	grain	¾.
Water	ʒijss.	

Mix, make solution, and add

Hydrochloric acid . . .	gtt.	iv.

or, in the form of pills:

℞.—Cornutin	grains	1⅓.
Hydrate of aluminium . . .	"	46.

add water and glycerine āā q. s. for twenty pills.

Dose, two to three pills.

The cornutin in solution generally is not to be recommended, as it becomes cloudy and unfit for use in a short time. In weak or inefficient pains the use of this drug is, according to Drs. Thomson and Erhard, not to be recommended, while in atonic hemorrhage or after abortion it is of great value. Especially rapid is its action in metro- and menorrhagia following endometritis, metritis and inflammatory conditions of the uterine appendages. In two cases of menorrhagia the result of endometritis, from one-third to one-half grain of the drug, subcutaneously administered, produced intense lumbar pains followed by complete cessation of the hemorrhage within ten minutes. The influence of the drug lasted for two hours, after which another dose was necessary. In a case of very severe metrorrhagia caused by double ovarian tumors, two three-quarter-grain doses gave entire relief.

The average dose of this drug is from one-thirty-second to one-eighth grain subcutaneously and from one-

eighth to one-fifth grain by the mouth.—*Wiener med. Presse*, March 31, 1889.

On the Treatment of Whooping-cough.—DR. TORDEUS, of the Hôpital St. Pierre, Brussels, in a clinical lecture on whooping-cough, concludes with a few words as to the treatment he adopts. He has no faith at all in the administration of preparations of belladonna for the purpose of preventing the development of the disease; the only prophylactic measure which, in his opinion, is worthy of any reliance being the rigid isolation of the patients. He recommends that as soon as whooping-cough has broken out in a family all the other members who have not already had the disease should be sent away, especially those who may be weak, rickety, or very young, as such are predisposed to bronchitic and pulmonary inflammations. Before the children which have been sent away are allowed to return, a thorough process of disinfection should be carried out, not only of the room occupied by the patient, but of all objects with which he may have come in contact. This is to be effected by means of carbolic acid, chloride of zinc, the vapor of sulphur, boiling water, or the hot-air chamber, according to the nature of the things to be disinfected.

As to medicine, during the early or catarrhal stage ipecacuanha and bicarbonate of soda should be given, with the object of rendering the phlegm less thick and tenacious; afterward, when the nature of the disorder has declared itself, germicides—as carbolic acid, salicylic acid, benzoic acid, sulphate of quinine, resorcin, etc.—should be prescribed. M. Tordeus especially recommends inhalations of a three to five per cent. solution of benzoate of soda, even in the case of very young children, though he does not specify the kind of apparatus he employs for this purpose. In order to moderate the violence of the attacks, bromide of potassium, oxide of zinc, belladonna, hyoscyamus, cocaine, antipyrin, or chloral may be given. As the disease is beginning to disappear, expectorants, such as chloride of ammonium, senega, and liquorice, are useful; and, finally, anæmia and debility during convalescence may be treated by country air, cod-liver oil, preparations of iron, quinine, and arsenic, and nourishing diet. Where symptoms of broncho-pneumonia show themselves, all depressing drugs must, of course, be avoided. In such cases M. Tordeus recommends wet packs and carbonate of ammonium, combined with alcohol.—*Lancet*, April 27, 1889.

Puerperal Infection.—As a result of numerous investigations, carefully carried out, DR. E. CZERNIEWSKI (*Archiv für Gynäk.*, vol. 1, No. 33, 1888) gives the following conclusions:

1. Microörganisms are found in the uterine cavity of healthy lying-in-women during the lochial discharge in exceptional cases only, from which it may be concluded that,

2. The lochia of healthy lying-in-women possesses neither pyogenic nor inflammatory properties. (Ott, Döderlein.)

3. Streptococci will be found in the lochia of the majority of lying-in women, even when the latter are only slightly diseased.

4. In fatal puerperal cases (especially lymphatic septicæmia) streptococci may be developed from cultures of the lochia, as well as from all secretions and organs after death.

5. The streptococci found in puerperal diseases are always the same, whether taken from slight or fatal cases.

6. The streptococci can cause erysipelatous inflammation and may lead to the formation of abscesses.

7. In infected cases the streptococci can cause degeneration of the parenchymatous organs.

Treatment of Acne.—DR. ISAAC, assistant to Dr. Lassar's clinic for skin diseases in Berlin, discusses in the *Berliner klin. Wochenschr.*, No. 3, 1889, acne and its treatment. As an etiological factor in the production of acne, he considers that hereditary peculiarities in the opening of the sebaceous glands may have an influence. In such cases the sebaceous duct is wide and funnel-shaped, offering a nidus for dirt and other septic material. Though such anatomical peculiarities may in exceptional instances predispose to acne, its causes are to be sought for in disturbances of the digestive, circulatory, or of the generative apparatus. The treatment in vogue at Lassar's clinic is the following:

℞.—Naphthol β	. . . . .	10.0.
Sulph. præcipitat.	. . . . .	50.0.
Saponis virid. } Vaseline }	. . .	āā 20.0.

This salve is applied thickly to the affected portion of the skin either by a brush or a spatula, and left *in situ* for from half an hour to an hour. On the following day one notices some desquamation of the epidermis and slight irritation and retraction of the skin. This procedure is repeated every day until desquamation of the entire epidermis has taken place. Should much irritation be produced, the treatment may be temporarily stopped and the affected surface covered with an indifferent powder or with Lassar's paste. For especially stubborn cases the following modification of the ointment may be applied:

℞.—Pulv. cretæ albæ	. . . .	5.0.
Naphthol β } Camphor } Vaseline }	. . . .	āā 10.0.
Saponis virid.	. . . .	15.0.
Sulphur. præcipitat.	. . .	50.0.

The addition of camphor increases the irritative power of the ointment, which in this form should only be left on the skin fifteen minutes.

Another formula which has been found serviceable in the treatment of acne is the following:

℞.—Resorcin } Zinc. oxid. } Amyli }	. . . .	āā 5.0.
Vaseline	. . . . .	10.0

—*Journal of Cutaneous and Genito-Urinary Diseases*, May, 1889.

Hyoscin.—DR. O. KLINKE (*Centralbl. f. Nervenhlk.*, No. 7), from a number of investigations made with this drug, reaches the following conclusions:

1. Hyoscin is, on account of its cheapness, tastelessness, and easy mode of administration, to be preferred to the other ill-tasting hypnotics now in vogue.

2. Subcutaneously as well as internally administered

one should always begin with the smallest doses, as individual tolerance of the drug varies greatly. Doses administered by the mouth should be double those administered subcutaneously; though the action of the former is somewhat retarded, it possesses the advantages of not inducing unpleasant and at times alarming symptoms. Preference is to be given to administration by the mouth, its sleep-producing action being far more certain when thus administered than when subcutaneously injected, although during the day-time the latter mode might be advantageously resorted to, to control quickly any unforeseen symptoms. It has never been found necessary to administer larger doses than $\frac{1}{250}$ gr.

3. Hyoscin paralyzes the motor and secretory centres, slows the pulse and respiration, produces dryness of the mouth and throat, and mydriasis, paralyzes the accomodation, disturbs the appetite and at times induces vomiting.

4. Hence it is used with advantage in the treatment of severe motor disturbances, constant talking, and especially in the maniacal condition of excited paralytics. In conditions of melancholia hyoscin is of little or no value, while morphia is the remedy *par excellence*.

5. No doubt remains of the power of this remedy of inducing hallucinations first of a despondent, then of an exhilarated character. It is, therefore, essential that it should be but sparingly given to recent mental cases, while older patients may receive larger doses, provided the existence of any cardiac complication be previously excluded.—*Prager med. Wochenschrift*, April 10, 1889.

Lanoline and Perchloride of Mercury.—According to a paper by DR. A. GOTTSTEIN (*Therap. Monatsch.*, March, 1889), lanoline with perchloride of mercury possesses several important surgical advantages. Koch has already shown the relative inefficacy of carbolized oil. Gottstein now asserts that although oil, lard, and fat completely prevent the action of antiseptics, lanoline with perchloride of mercury is as powerful a disinfectant as an aqueous solution of the perchloride. In the treatment of large ulcerated surfaces he considers that this combination will be serviceable, as it will minimize the risks of absorption, while it will insure a more complete covering of the affected part, and its preservative action will be more continuous. Ebstein, in the *Deutsche med. Woch.*, confirms these views, and recommends the employment of this combination in the treatment of threatened bedsores; and from Dr. George Meyer, of Berlin, comes the suggestion that it can also be used to protect the hands of surgeons during antiseptic operations. The roughness and disfigurement of the hands, caused ordinarily by strong solutions of carbolic acid, are said to be obviated by lanoline. In spite of the conflicting statements hitherto made of the absorptive powers of lanoline, it appears to have been conclusive proved that, even in the absence of perchloride of mercury, it is unfavorable to the percolation and development of microörganisms. It is highly probable that its true use as a protective has now been established by Dr. Gottstein.—*Lancet*, April 27, 1889.

Arsenic in Malaria.—DR. RICCHI, in a paper read before the Società Medico-Chirurgica, of Bologna, on March 8th, gave his experience of arsenic in the treatment of malaria. He had been able to test it on a large scale, having been in medical charge of the officers and servants of the Adriatic railway system for several years. His experiments were made in districts where the disease was particularly rife. Of 2501 men on whom the method was tried, 579 were suffering from acute and 1384 from chronic malaria. The remaining 538 were free from the disease, so far as persons can be so who live with scarcely any hygienic precautions in places where it is endemic. In the acute cases arsenic was of little use, but it gave excellent results in the chronic cases, and in the others it seemed to confer immunity, or, if they contracted the affection, it was of a mild type and easily cured with quinine. The men put on flesh and lost the pallid, cachectic look characteristic of dwellers in malarial regions. According to Dr. Ricchi, there can be no doubt that "the daily administration of arsenious acid increases the resistance of the organism to the action of the microbes of malaria." The treatment must be methodically carried out—that is, the drug must be given in time and continued as long as may be necessary.—*British Medical Journal*, April 27, 1889.

A New Deodorizer for Iodoform.—CAUBRELLE (*Bulletin de Thérap.*, cxiii. 9) recommends the following formula for deodorized iodoform:

℞.—Iodoform	. . . . .	grs. 15.
Menthol	. . . . .	gr. ¾.
Ess. lavender	. . . .	gtt. j.—M.

A little spirits of lavender added to the water in which the hands are washed will completely remove the odor of iodoform from them.

Kefir in Children's Diseases.—Kefir, a substance something like koumiss, made in the Caucasus, has long been utilized as a stimulant and easily digested food in various wasting diseases, such as phthisis. Until recently, however, it was but little known beyond the locality of its origin. Kefir has of late attracted some attention, and has been employed in some of the hospitals both of France and Germany. DR. E. KRAUSS, of the Children's Department of the Vienna Polyclinic, has collected a good deal of valuable information on the subject, which he publishes in a Vienna medical journal. Kefir consists of milk which has undergone two distinct kinds of fermentation—the alcoholic, produced by the yeast-like cells of the ferment, and the lactic acid fermentation, due to a bacillus also contained in the kefir; the actual contents being alcohol, lactic acid, carbonic acid, and peptone. It has been given to children as young as two months, and is said to have proved most valuable in gastric and intestinal catarrh.—*Lancet*, April 27, 1889.

Infantile Dyspepsia.—DR. M. J. SIMON, in the *Gazette hebd. de Méd. et de Chir.*, prescribes the following in cases of infantile dyspepsia:

℞.—Codeine	. . . .	gr. $\frac{1}{32}$ to $\frac{1}{15}$.
Magnesia Powdered crabs'-eyes	} . .	āā grs. 2.
Rhubarb	. . . .	gr. 1.
Nux vomica	. . . .	gr. $\frac{1}{8}$.—M.

One powder of the above formula should be given after each meal.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE . . . . . $5.00.

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,

PHILADELPHIA.

SATURDAY, MAY 18, 1889.

FILTRATION THE BEST MEANS OF PURIFYING THE PUBLIC WATER SUPPLY.

No one will dispute the statement that an abundant supply of pure water is essential to the health and comfort of a community. Yet this great truth is either not properly appreciated, or its application is beset with extreme difficulties, for it is seldom that the water supplied by public works reaches a proper standard—of purity, at least. It is generally not a serious problem to obtain water in sufficient quantity for all municipal purposes, but there is frequently great difficulty in securing the proper quality. The reason is that our rivers, which are the main source of supply, are allowed to become polluted, and the evil is extending with the growth of population. Community of interests should proscribe this pernicious practice, but it does not. Legislation in this country has done very little in protecting our streams from gross pollution. No such law as the Rivers Pollution Act of England exists upon our statute books, although the necessity for such a restriction is plainly apparent.

Water polluted by sewage is unfit for use, and dangerous without purification. Apart from the conditions which give rise to disease of mild type, there is the possibility of impregnation with disease-germs which may lead to widespread sickness of a serious character. The wisest and the most economical plan, if universally adopted, is the radical measure of prevention, but as this is a utopian conception, individual communities must resort to some other method to insure the purity of their water-supply. Sedimentation, filtration, aëration, and chemical treatment are the means of purification at our disposal. All of these plans may be used conjointly, but that by filtration, which includes sedimentation, is the most practicable and efficient, and the one most commonly employed. In fact, filtration is the only possible means of removing, on a large scale, the infectious matter which water sometimes contains. Domestic filtration, which is practised to a limited extent, is at best but a partial remedy, and is often most unsatisfactorily performed. The aggregate expense imposed upon the people for its maintenance would go a great way toward procuring the most complete purification of the entire public supply.

Beside sedimentation, by which particles of suspended matter which produce the discoloration fall to the bottom, there may be used as preliminaries to filtration, both artificial aëration to assist in oxidation, and chemical treatment by which substances are added to the water in order to coagulate and render insoluble contained impurities. But filtration is the main feature of purification, by which, as Frankland and others have demonstrated, it is possible to deprive water of germ life and render it otherwise potable.

In most of the large cities of the old world, and in some of the smaller cities in this country, filtration works are deemed necessities and are maintained with the most satisfactory results. The *Deutsche medizinische Wochenschrift*, No. 3, 1889, contains an instructive account of the filtration works at Berlin, and the mode of testing their efficiency. These works have been constructed within recent years after the most approved plans, and have been operated with great satisfaction. They may therefore be looked upon as model works. There are in operation eight open and sixteen covered filters of great magnitude, which collectively are capable of delivering daily 100,000 cubic metres of filtered water. The filter-beds are composed, in the usual manner, of layers of stone of different sizes, gravel, and sand. The water is allowed to stand at least twenty-four hours before the process of filtration commences, in order to allow the deposition of suspended matter to take place. The layer of organic and inorganic matter thus formed is of great service in holding back most of the bacteria. When the purifying power of the filter begins to fail, as indicated by

proper tests, the water is drawn off, the sediment removed, and the renovated works again set in action.

In order to determine the efficiency of the process, weekly tests are made of the unfiltered water and of samples taken after filtration both from the basins and from the service pipes in a number of places throughout the city. Each test includes a chemical and a bacteriological examination of the water. No matter how great or variable the quantity of bacteria in the water before filtration, the relative number in the filtered water varies but little from a very low average. Rarely does the number of organisms in water taken from the service pipes exceed three hundred per cubic centimetre. The bacteriological examination has further demonstrated that there is no perceptible difference between the water in the service-pipes and that delivered fresh from the filter-works. The results thus obtained have led the authorities to establish a bacteriological station at the water-works, and to abandon the examination of the water in the city as superfluous.

The results of the experience of Berlin illustrate two important facts: That filtration is a practicable and thoroughly efficient means of purification of public water supplies; in fact, the only means of removing, on a large scale, infectious matter from water; and that bacteriological examination is the only means of testing the efficiency of the process. These facts are of great moment to every community depending on public works for its water supply, and well worth pondering and turning to useful account. It seems incredible that communities of wealth, intelligence, and progressive spirit are content to use water just as it may happen to come from the river or collection basins, often repulsive to sight and taste from scourings of the watershed by heavy rains or from excessive proportion of organic matter in times of drought, and rendered unwholesome by contamination by the sewage and excreta of the population resident on its banks, without any attempt at artificial purification. The health of the people is paramount to all other considerations, and in conducing to this object no measure is comparable to the provision of a water supply of the highest attainable purity.

HYDROGEN PEROXIDE IN DIPHTHERIA.

THIS subject has in part engaged the attention of two successive meetings of the Kings County Medical Association, Brooklyn. The remedy is undoubtedly one of great potency, but it does not rapidly advance in professional esteem, for the reason that its preparation and administration are not unattended by difficulty; or, more properly expressed, they require some attention and care. The undilute peroxide being very unstable, it is only found in the drug-stores in solution in water containing a small proportion of hydrochloric acid. A fifteen-volume solution is prepared, which contains fifteen fluidounces to the pint, the cost of which is nine dollars per dozen pint bottles. Below 59° F. this solution will maintain its oxygen fairly well, but above that point its efficiency decreases. It should, therefore, be kept in a cool place; the heat of the hand is sufficient to liberate the gas, and hence the bottle should be handled by the neck and carried by a string attached to its neck. The fifteen-volume solution is not to be used in its full strength, but should be diluted for all spraying or injection purposes; three ounces of the above solution, if added to a pint of water, will be strong enough for adults, and two ounces to the pint for children. Spraying apparatus should be of hard rubber, and not of metal, since the oxygen readily attacks most metals, and the resulting solution might be injurious. The two-volume solution, just referred to, may be used every three hours, or oftener, in the case of children, the nose, throat, and mouth being flooded by means of a spray-producer. The excess of the solution that may find its way into the stomach or larynx is not harmful, but rather beneficial. Patients old enough to gargle should use the three-volume solution in that manner.

The dosage above given is that recommended in a paper by DR. E. R. SQUIBB, before the Association above mentioned, published in *Gaillard's Medical Journal* for March. Since the reading of that paper, some considerable trial of the drug has been made, with generally good report. From the testimony of some of these experimenters, the cleansing and disinfecting powers of the peroxide surpass those of any application heretofore tried by them. Its administration is quite unobjectionable, even to the young, the solution being only slightly acidulous in taste, odorless, and colorless. There is a kind of after-taste or impression that is not lasting nor essentially disagreeable—less so than in case of most of the medicaments used in this affection.

To sum up the case, it would appear that in this relatively tasteless and innocuous solution we have about the best of the antiseptics and cleansers that

are known to chemistry, and one that is far less prone to toxic risks than some of the solutions—as, for example, corrosive sublimate—that have been widely used of late. There are other uses of this peroxide, where the throat and mouth require strict cleansing, as in scarlet fever; also in uterine cancer, and in indolent sores where deodorant action is indicated. In the last class of cases a one-volume solution will commonly be sufficiently strong. In cancer it can be used indefinitely strong, or until the disinfectant effect is attained.

A CONVENIENT MODIFICATION OF THE COLD-WATER TREATMENT OF FEVER.

There can be no doubt that the safest, if not the most effective, of all antipyretic agents is sponging the surface of the body with water, either tepid, cool, or cold. A still more effective and quite as convenient method of applying water to the skin is in the form of spray as described in a recent number of the *Prager medicinische Wochenschrift*. Preyer published an account of this method in 1884, although it had been employed somewhat earlier by Flashar. In 1886 Hiller applied it to the treatment of sunstroke. Placzek modified the procedure by spraying first with cold water (53°–60° F.) and directly after with warm (95° F.). In this way he produced a fall of two degrees in the temperature of a febrile animal. The warm spray produces a rapid dilatation of the skin capillaries and consequent dissipation of heat.

Such measures as these, which are in close imitation of the natural processes of heat regulation, deserve the most careful study. Their soothing effect upon the nervous system is in marked contrast to the prostration so often induced by the antipyretic drugs that have been lately introduced in such numbers.

The San Francisco Polyclinic was opened on March 1st for post-graduate instruction. It is proposed to build a hospital in connection with the institution.

The Trustees of the Jefferson Medical College, last Monday, elected Dr. William W. Keen to the Chair of Principles of Surgery and of Clinical Surgery, rendered vacant by the death of Dr. Samuel W. Gross. Dr. Keen has been a most able teacher of anatomy and surgery for more than twenty years, and a surgeon of large operative experience. His reputation for sound judgment, scholarly attainments, and successful teaching give assurance that he will well maintain the fame which the Chair of Surgery at Jefferson has for so long a period enjoyed.

The annual meeting of the Association of Medical Superintendents of American Institutions for the Insane will be held at Newport, R. I., June 18th next.

The fourth session of the French Congress of Surgery will be held at Paris, on October 17 and 18, 1889, Baron Larrey presiding. The following questions will be the order of the day: 1. Immediate and after results of operations for local tuberculosis. 2. Surgical treatment of peritonitis. 3. Treatment of aneurism of the extremities.

What is more interesting than the analysis of the intellectual workings of a great mind, when made by himself? Dr. Holmes has just done this for us, on a limited scale, in a letter published in the *Canadian Medical and Surgical Journal*, April, in reference to a commendatory comment written by Dr. William Osler concerning the part taken, long years ago, by Dr. Holmes in teaching correct views on the subject of puerperal fever. The genial Autocrat writes as follows: "There was a time certainly in which I would have said that the best page of my record was that on which I fought my battle for the poor poisoned women. I am reminded of that essay from time to time, but it was published in a periodical which died one year after life, and it therefore escaped the wide notice it would have found if it had been printed in *The American Journal of the Medical Sciences*. A lecturer of one of the great London hospitals referred to it the other day, and coupled with it some fine phrases about myself which made me blush either with modesty or vanity, I forget which. I think I will not answer the question you put me. I think often of the "Chambered Nautilus," which was a favorite poem of mine, if I wrote it myself. The essay only comes up at long intervals; the poem repeats itself in my memory, and is very often spoken of by my correspondents in terms of more than ordinary praise. I had a savage pleasure, I confess, in handling those two professors, learned men both of them—skilled experts, but babes as it seemed to me in their capacity of reasoning and of arguing. But in writing the poem I was filled with a better feeling, a higher state of mental exaltation, and the most crystal clairvoyance, as it seemed to me, that had ever been granted to me. I mean

that lucid vision of one's thought, and all forms of expression which will be at once precise and musical—which is the poet's gift, however large or small in amount or value. There is a more selfish pleasure to be had out of the poem, but perhaps a nobler satisfaction flows from the life-saving labor."

A SPECIAL meeting of the *Sei-I-Kwai* of Tokio was called last month, in memory of the death of DR. DUANE B. SIMMONS, which took place in Tokio on February 19th. Dr. Simmons was a native of Milan, Dutchess Co., N. Y., and was one of the oldest foreign residents in Japan, having been there since 1859. He has done much toward the advancement of medical science in Japan, and the present excellent condition of the Medical School of the Tokio University is largely due to his untiring zeal. The meeting of the *Sei-I-Kwai* was not attended by members of the medical profession alone, but Japanese journalists, politicians, and statesmen joined with the profession in paying tribute to his memory.

SOCIETY PROCEEDINGS.

PHILADELPHIA ACADEMY OF SURGERY.

Stated Meeting May 6, 1889.

THOMAS G. MORTON, M.D., IN THE CHAIR.

DR. H. PACKARD read a paper on

SEPARATION (COMPOUND) OF LOWER EPIPHYSIS OF FEMUR; AMPUTATION.

Owen McK., æt. nine years, was admitted to St. Joseph's Hospital April 16, 1889, having had his right lower extremity caught in a wheel of a wagon behind which he was hanging.

A very large ragged wound existed at the back of the thigh, very low down, involving the popliteal space. Through this wound the end of the shaft of the femur protruded, stripped cleanly of periosteum, and showing the nodulated surface which had fitted to the epiphysis. The condyles were still in contact with the articular surface of the tibia, but tilted so that, as the boy lay on his back, their cartilaginous covering looked upward. They were also pressed toward the posterior part of the limb, so that the tibia seemed as if partially luxated forward.

Very little blood had been lost, and the boy's general condition was excellent. He was etherized, and a careful examination made. The soft parts were found to be very extensively torn, but the vessels were apparently whole. The foot and leg, however, were markedly colder than on the opposite side. On extension, the end of the shaft could be reduced, but the tilting of the epiphyseal portion could not be overcome so as to restore the proper relation of the two. Resection was considered, but rejected for two reasons: in the first place the position of the epiphysis, and in the second place the great probability that the vessels had suffered and that secondary hemorrhage would ensue, or gangrene of the limb below if they were plugged. The limb was, therefore, amputated, with a long anterior flap, the bone being sawed through about an inch and a half above the end of the shaft. The bruised and torn muscular structures were carefully removed. A large periosteal covering was laid over the sawed end of the bone and sutured with fine catgut. Sutures were also applied to keep the deeper tissues in contact, and the lips of the wound were approximated with silkworm-gut, shotted.

On examination of the amputated limb it was found that the tilting of the epiphysis was due to the upward pull of the quadriceps femoris upon the patella, and to the attachment of the heads of the gastrocnemius to the posterior portion of the epiphyseal fragment. With the exception of a very small chip torn from the anterior edge of the end of the diaphysis the lower fragment seemed to consist of the epiphysis alone, separated exactly at the line of union between the two ossifying portions.

This seems to me to be one of the points of interest in this case; another being the tilting of the epiphyseal portion and its cause, which, so far as I know, has not been noted in any other instance hitherto reported. Another point of some importance is the condition of the vessels, which, it seemed at first sight, must surely have been torn across. That they were not so torn—and they are said to have escaped in several of the other cases on record—seems to me to be attributable in part, at least, to the twisting of the limb at the time of the accident, the shaft of the bone not following the rapid movement of the lower portion, so that the vessels and nerve were caused to slide over it in an inward direction, instead of being stretched over it as it was forced backward.

This particular accident, as is well known, has been noted as the cause of separation of the lower epiphysis of the femur in more than half of the recorded cases. I believe the statement of Reverdin holds good, that in only two instances has the attempt to save the limb been attended with success.

The boy has done remarkably well; a small slough separated from the edge of the anterior flap, but the aseptic condition of the wound was not interfered with by this circumstance, healing being now almost complete on the seventeenth day.

DR. JOHN H. BRINTON desired to exhibit another specimen of the same injury with a brief report of the case. The specimen was presented seven years ago to the museum of the Jefferson Medical College, by Dr. Willis T. Davison, of Pennsylvania. The patient was a boy twelve years of age, who, while riding on the back of a buggy, had his left foot caught between the spokes of the wheel and carried forward, producing a separation of the epiphysis with a slight nipping off of one portion of the edge of the diaphysis, as shown in this bony preparation.

A few hours after the accident the patient was seen by Dr. James Davison, of Canton, Pa., who found an oblique wound, four or five inches long, extending across the upper portion of the popliteal space. The skin, superficial fascia, and muscles were severely lacerated, and there was copious venous hemorrhage and extensive extravasation around the joint and upper part of the leg;

no pulse could be felt in the posterior tibial artery. The boy was able to turn over and imperfectly raise the knee from the bed. An unsuccessful attempt was made to save the limb, but amputation was necessary on the fourth day, and the patient made a good recovery.

Careful dissection of the amputated limb showed that the epiphysis had been torn from the diaphysis, and the artery injured in such a manner that a probe could with difficulty be passed through it. It was also found that there was a rupture at the posterior part of the synovial membrane opening the knee-joint.

The account given by Dr. Packard of his case would apply almost without alteration to this one. It was thought by the reporter of this case that the leverage was exerted by the bone being caught between the spokes and the cross-iron of the buggy. At the time this case was reported it was believed to have been the seventh instance of this injury.

DR. PACKARD stated that the specimen did not represent the full amount of bone exposed and deprived of periosteum. The injury to the soft parts was very great. The bruised and lacerated tissues were cut away with much care. His first idea was to resect and apply the end of the diaphysis to the surface of the epiphysis. He found great difficulty, however, in replacing the epiphysis, and could not at the time tell what the reason was. It seemed to him scarcely justifiable to make incisions to free it. He thought that the attempt to save the limb would subject the patient to greater danger than amputation. There was also great probability of injury of the vessels, with the danger of secondary hemorrhage or gangrene of the whole limb, and possibly blood poisoning. Under these circumstances it seemed to him that the proper course was amputation.

According to Reverdin, the attempt to save the limb has been successful in only two out of about thirty cases of compound separation of the lower epiphysis of the femur.

DR. CHARLES B. NANCREDE disclaimed any criticism of the treatment employed in this case, but wished simply to report an instance of involuntary conservative surgery, showing what can sometimes be effected in the injuries of children. A child three and one-half years of age was run over by a loaded coal-cart, the wheel traversing the groin just below the line of Poupart's ligament. For about two-thirds of the diameter everything down to the bone was crushed. The bone was broken and the skin also stripped from the muscles on the outer side of the limb. Everything was crushed except a bridge of skin and muscle on the outer side. The femoral vessels which traversed this gap, filled with coal-dust, was all that was left on the inner side except a portion of the adductor longus. He, of course, suggested the propriety of amputation, but was allowed to do nothing. He did his best to drain and antisepticize the wound. On the fifth day, just as the dressing was removed, the femoral artery gave way. He caught it and tied it above and below the profunda. Inside of half an hour the collateral circulation was established. This was over thirty days ago. The bone is covered with granulations; secondary abscesses have formed and been drained. But while the child is steadily losing ground, so far it has survived an apparently hopeless injury *without* amputation, and may yet recover a useful limb.

DR. MORTON read a paper on

THE TREATMENT OF CLUB-FOOT.

(See page 542.)

DR. J. H. PACKARD said that it is highly important that after the operation the development of the muscles shall be attended to. This idea is, of course, not a new one, but it deserves fuller appreciation than it has generally received. A year ago he operated on a case, removing the astragalus for caries. Six months later the child was brought to him on account of a tendency to draw the knee back. All the muscles were wasted and the limb was decidedly smaller than the other. The child walked badly. He directed the mother to make systematic massage of the muscles; the result has been a marked improvement in the gait. He supposed that there is nothing better established than that there is a nervous element at the root of all these troubles. His own observation has been that in cases of one-sided club-foot there is a decided difference in nutrition in favor of the sound limb as against the distorted limb. He doubted whether sufficient attention is drawn to this matter of the development of the muscles.

EIGHTH GERMAN CONGRESS OF INTERNAL MEDICINE.

Held at Wiesbaden April 15th to 18th, 1889.

(Continued from page 531.)

(Specially reported for THE MEDICAL NEWS.)

DR. DETTWEILER, of Falkenstein, read a paper on the

INFLUENCE OF SPUTA AS A MEANS OF TRANSMITTING TUBERCULOSIS.

In an article written by Dr. Cornet in the *Revue d'Hygiène* last year, the author draws particular attention to the danger of contagion by the sputum, by handkerchief, by the floor, by the spittoon. The expired air is not contagious, and the tubercular patient becomes dangerous only by his sputa, the only source of contamination being the specific bacillus.

If we prevent the patient from spitting anywhere he likes, if we thoroughly disinfect all the clothes which may have had sputa in contact with them, we have done all in our power to prevent the patient from being a source of contagion to the persons who surround him.

In the hospital spittoons have been introduced which, unluckily, are not hermetically closed. In private practice, however, the state is even worse, for the patient will expectorate in his handkerchief, and, if no one is present, he will not hesitate to do it on the floor. In this manner he becomes a source of infection, a great danger to those in immediate contact with him. At church, in stores, saloons, theatres, etc., these patients are a danger for those who come after them. This would explain more readily the heredity of tuberculosis, for, whatever may be the favorable state of an organism for receiving the disease, one can only become tuberculous by the medium of Koch's bacillus.

It is then necessary to interfere, and prevent all these phthisical patients from infecting, by means of their sputa, their handkerchiefs or the floor of their room; and he thought it necessary that any family that has a phthisical patient must be informed of the danger to

which they expose themselves if they are not strictly careful. We, as physicians, must combat as powerfully as we can the habit of spitting in handkerchiefs, the source of most infections.

PROF. EBSTEIN, of Göttingen, then read a paper

ON THE PATHOGENY OF GOUT.

He said two forms of gout are usually described, an articular form and a renal one. Articular gout is a chronic form; tophi will appear during as well as after an attack of the disease.

The idea of Garrod, that these formations of crystallized uric acid occur on account of the gouty inflammation, is not admissible; our anatomical and experimental researches demonstrate and prove it certainly. Uric acid is a chemical poison which determines or produces a necrosis much more easily than an inflammation.

It is because these tissues are in a state of necrosis that we have these formations of crystallized uric acid. This conception of the previous necrosis of the tissues, under the influence of the uric acid poison, explains why we meet with severe visceral or other gouty affections without any traces of tophus.

The toxicity of uric acid can also only show itself in a transitory form. Its presence irritates the tissues, but when it has disappeared the symptoms all disappear, and it would be very difficult to find any traces of its passage; this fact applies to nearly all chemical poisons.

The most interesting gouty manifestations are certainly those which concern the viscera, and especially those of the digestive apparatus and its allied parts. The participation of these viscera has been the point of departure of a great many theories on the pathogeny of the gouty affection. However, whatever may be the theory adopted, one cannot conceive that an excessive uric acid formation could alone start a gouty attack. He could not accept the opinion of Garrod, who explains gout as being an excessive production of uric acid and temporary incapacity on the part of the kidneys to eliminate this acid.

There are several causes which can produce a stasis of uric acid; amongst them all the functional diseases of the kidneys, or any retention of used-up material due to a morbid modification of the nutritive changes; in this last example it is the kidney which is primarily involved by gout, and we have then to deal with the primitive renal gout, which is a very fatal form of the affection.

The crystalline deposits of uric acid explain sufficiently the anatomical lesions of the primary gout of the articulations. The marrow of bones and the muscles created, so to say, almost exclusively the uric acid, which, starting from these points of origin, passed into the lymphatic channels, to infect finally the whole mass of the blood. The uric acid which is carried about by the blood undergoes no further modification, and the kidney eliminates it without its having lost its distinctive characters. The uric acid impregnation of the blood is a very easy matter. The acid travels very slowly along the lymphatic channels, and the gouty deposits are nothing more than so many points of arrest for the acid. The fact that, in gout, the heart and bloodvessels are often involved, proves the necessity of a temporary stasis for the realization of a gouty attack.

It is in those conditions, which will allow the local stasis of uric acid, that he finds the connecting link which unites gout to rheumatism on one side, and to syphilis on the other.

DR. PFEIFFER, of Wiesbaden, then spoke of the

TREATMENT OF GOUT.

Gout does not always manifest itself by involving the kidneys or articulations; the skin is often involved and in an isolated manner; gouty affections of the skin are sometimes so marked that the swelling and redness may be taken for an abscess, but we all know that a gouty abscess has not yet been discovered. On the other hand, we have a gouty patient who complains of pain in the knee; one believes in a gouty attack, but when we look more closely, we are surprised to find that the communicated articular movements are not at all painful. This is because the attack does not involve the articulation itself, but is located exclusively on the external integument. Often the first tophi are met with on the skin, and the skin of the fingers only sometimes; the patient does not notice them. Gout before becoming articular is nearly always dermic. In a patient he has discovered an enormous tophus on a level with the elbow, without its presence having produced the slightest pain. He did not believe in the necrotic process of gout; a deposit of urates can determine a violent inflammation, but this never extends to a real necrosis. The necrosis of a tissue during an attack of gout is nearly always due to a traumatic lesion; in a gouty patient, who was continuously fencing, the necrobiosis of tissue due to gout occurred on his right hand. The gouty individual eliminates much less uric acid than the normal person; in the first the uric acid, which is present in great quantities in the serum of the blood, is no more eliminated, because it has lost its exosmotic power; the organism produces more uric acid than it eliminates; and when the attack of gout supervenes the uric acid has almost completely disappeared from the urine, and it is only at the period of acme of the attack that uric acid is eliminated in excessive quantity.

When the tophus is once formed, it will not increase in size. The contrary was believed on account of the inflammatory states of the tissues which surround the urate deposits.

The hypodermatic injections of uric acid are extremely painful, and the result is exactly the same whether we use for these injections, instead of uric acid, the acid phosphate of soda; this is what occurs in an individual in normal health. If these same injections are made in gouty patients, no pain will be experienced; this is an excellent process for differential diagnosis. This result is easily explained by the following experiment: If before making the subcutaneous injections of acid phosphate of sodium, we render the organism alkaline we shall experience a great deal of pain, which one would not feel in the normal state. By rendering, on the other hand, the humors of the organism acid, by taking internally a small quantity of hydrochloric acid, the injections of acid phosphate are absolutely innocuous. The alkaline state of the liquids of the whole organism is, therefore, the cause of the pain described above.

The treatment requires the compliance with an important indication, namely, to keep the uric acid in a powerful state of diffusion. For this purpose a careful diet is necessary. He thought that we make a mistake in suppressing too rapidly the dark meats; for the only

serious danger from gout is the gouty cachexia, which comes early if the patient is not sustained; we must, on the contrary, give as much albumin as we can, for the suppression of meat is against the chemical indication. He thought meat is much to be feared, his experiments having shown that the uric acid is derived almost exclusively from the hydrocarbons. He does not allow milk under any condition. As a general rule, hydrocarbons must be given to gouty patients in the smallest proportion possible.

Alcohol and wine, diminishing the diffusibility of uric acid, must be strongly forbidden. When a gouty attack comes on, the patient must not be allowed to remain too long in bed, for in doing so he postpones and prolongs the disappearance of the attack; he must take out-door exercise.

As to the medical treatment, he knew of but one, the alkalinization of the blood to the extremest degree. To bring on this condition we must act with a great deal of care and begin the treatment by very small quantities of alkalies. He has seen patients who, under the influence of a large quantity of alkaline water taken at the beginning of the treatment, have had the severest attack of gout possible; we must, for this reason, begin with very small doses and progressively increase our medication.

Alkaline baths are also to be recommended. Against the articular pains he gives 30 or 45 grammes a day of salicylic acid; this will promptly relieve the pain. Extremely diluted hydrochloric acid will do better than the salicylic acid.

M. FÜRBRINGER, of Berlin, then read a paper on

VIRILE STERILITY.

A great distinction must be made between impotentia generandi and impotentia coeundi: the first consists in the sterility due to aspermia—that is, the absence of spermatozoa in the seminal fluid, when there are no other essential alterations in the accomplishment of the sexual connection.

In this paper he considered only the impotentia coeundi, which Rockwell and Hammond have studied under the name of sexual neurasthenia, and he did not consider the different organic causes (such as those due to syphilis, gonorrhœa, traumatism, etc., which bring on impotentia coeundi on account of the pain or incurvation or other alteration having an anatomical basis).

In nervous impotency, the insufficient erection is the principal cause of impossibility of coitus. Sexual impotency of purely physical origin, without any appreciable neurasthentic phenomenon, is much the less frequent; impotentia coeundi coexists nearly always with indications of irritative feebleness, and can, like spermatorrhœa, which usually accompanies it, constitute in most cases the only symptom of a neurasthenia. While he has collected one hundred cases of impotentia generandi he has two hundred cases of impotentia coeundi, of purely nervous origin, which nearly all have occurred in his private practice. Out of 15,000 patients whom he has treated at the hospital he has met only two cases of this functional trouble. He does not think it is more exceptional in the working classes, and he attributes our lack of knowledge in those cases to the carelessness with which the sexual act is accomplished.

The extreme ages at which he has met this affection are eighteen and fifty-two years; 50 per cent. of his patients were in their fortieth year. His statistics indicate a greater frequency in business men, officers, and, above all, physicians; it is not rare in theologians, and, lastly, professors are at the bottom of his list. As to the early histories of these cases, he has found that 28 per cent. were due to onanism; 38 per cent. to gonorrhœa; onanism and gonorrhœa combined, 13 per cent.; excess of natural coitus, 10 per cent.; hereditary irritative weakness, 11 per cent. It is to be remarked that spermatorrhœa and the voluntary suspension from coitus do not give origin to a special form of the affection, and that it is the sexual excesses and not their accomplishment against the laws of nature which have an influence in this respect. In all these patients the general state varies with the more or less prominence of the phases of this nervous impotency, the associated symptoms of which consist of headaches, disturbances of vision and speech, in phenomena of nervous dyspepsia, in more or less marked cardiac disorders—in a word, to spinal irritation.

The analysis of the four distinct phenomena which occur in the sexual act—erectio, libido sexualis, ejaculatio, orgasmus—permit us to distinguish four principal forms of impotentia coeundi.

In the first, which is the most frequent, there exists, independently from insufficiency of erection, a more or less pronounced weakness of the desire, of the ejaculation, of the orgasmus. In this form, which affects at the same time the four parts of the sexual act, we must take into consideration the female coldness which is quite common in Germany; in certain less frequent cases, it is less an impotentia virilis than a impudentia muliebris.

The second form, characterized by nearly the same symptoms, differing from the first only by the exaggeration of the sexual desire, is accompanied by frontal headache, and requires a bad prognosis.

The third form, characterized by a precocity of the ejaculation, constitutes an insensible transition between impotentia coeundi and diurnal pollutions.

In the last form the desire and ejaculation exist, but the erection is abnormal on account of mixed cerebral activity or professional preoccupations.

To establish the diagnosis of impotentia coeundi, we must carefully examine the urine for sugar or albumin, and look if we can find any signs of locomotor ataxia or cerebral tumor, such as syphilitic gummata.

As to the prognosis, it depends on the degree of neurasthenia. His statistics have given him one-third of cures and one-third of ameliorations. We must hold ourselves on the reserve for the local treatment, which is useless so long as there is no inflammation of the urethra, and which exerts even, in a moral point of view, a bad influence, in cases where the impotency is of a purely nervous character.

To hygienic conditions, above all, must therapeutics owe its beneficial influence; we must, according to the case, oblige our patients to take physical and intellectual rest; forbid any sexual intercourse; recommend travelling; and in many cases, a stay at a special place for the treatment of the neurasthenia.

Hydrotherapy and massage can in those cases render good service; but the results obtained by these methods are far from being satisfactory. As to the question of marriage, this should be left to the appreciation of the physician for each special case.

DR. KLEMPERER, of Berlin, read a paper on

DILATATION OF THE STOMACH AND ITS TREATMENT.

In Dr. Leyden's clinic he had observed seventeen cases of dilatation of the stomach with narrowing of the pyloric orifice. In eight of these the quantity of hydrochloric acid in the gastric juice was below normal; in seven it was greater than normal; and in two it was equal to normal. He had studied with great care the relations existing between dilatation of the stomach and gastric hyperacidity, and he had observed twenty-one cases of hyperhydrochloridity, which he divided into two sections:

1. In twelve cases of hyperacidity with preservation of the motor functions of the stomach the patient presented all the symptoms encountered in nervous dyspepsia; in these cases cure has always been very difficult. But in these patients, notwithstanding the hyperacidity, the stomach did not undergo dilatation, and he thought that these cases ought to be classified as secretory neuroses.

2. In this section he placed cases of hyperacidity with weakening of the motor power. He placed in this group those cases in which the hyperacidity and motor weakness were due to an irritation resulting from a too copious feeding. In this group he also placed four cases characterized by a hypersecretion, and a case of hyperacidity accompanied by a well-marked diminution of the saccharifying power of the saliva upon starch. In several cases the motor weakness of the stomach was the first to appear, so that the hyperacidity can be due to the great length of time during which food is kept in the stomach. In this class belongs the dyspepsia of phthisis.

As a cause for the weakening of the gastric motor power a torpid state of the vagus nerve has been suspected: this theory appeared to him much more acceptable, since he has had the opportunity to observe gastric dilatation occurring simultaneously with palpitation of the heart; when this weakening of the motor power is prolonged the state of hyperacidity may be replaced by a lack of acidity.

He thought that a weakness of the gastric motor power is very often the sole primary cause of gastric dilatation. This state may be primary or secondary, and results from the irritation produced by undigestible food; but the hyperacidity of the gastric juice cannot be considered as a cause of ectasy. It is not always easy to treat such cases; but it would be contrary to accepted opinion to assert that, when a dilatation is once produced, it will not disappear again. He had had the opportunity to observe an enormous dilatation of the stomach, which came on in four weeks' time, as a result of poisoning by an acid. After a resection of the pyloric end of the stomach, the stomach returned to its primitive form, as he had been able to verify by an autopsy of the patient, who, being phthisical, died a few months later from tuberculous disease. In cases, however, in which the dilatation comes on gradually and takes a chronic form, the return to the normal condition is no longer possible, but a well-understood treatment can restore the motor power.

His treatment of these cases is as follows: Washing out the stomach in the evening with a small quantity of water, using an aspirating apparatus, and carefully regulating the diet. Many authors recommend a meat diet, thinking that the stomach is able to digest meat rapidly, but as a result of his researches he has found that in dilated stomachs absorption is very much restricted. It is necessary, however, that the intestine should receive as much food as is requisite for the preservation of the tissues, and for this purpose, 18 ounces of fat and 3¼ ounces of hydrocarbon are to be recommended for one day. The fatty matter must be given in the form of cream and the hydrocarbon as glucose. Bread can be given as part of the alimentation of such patients, and a certain quantity of alcohol would also be of benefit. In addition to the above, electrical treatment and massage are recommended.

PROF. EBSTEIN, of Göttingen, read a paper on

EXPERIMENTAL FORMATION OF RENAL CALCULI.

He had made with M. Nicolaier experiments on dogs and rabbits, and they were able to produce in these animals, by introducing oxamide in their food, renal calculi, the largest of which were localized in the pelvis of the kidney, while the gravel and small grains of sand could be found in any part of the urinary apparatus. The ingested oxamide was white, while the renal concretions were of a grayish-yellow; the largest of them presented on their surface asperities and elevations. The calculi were very hard, and after attrition they observed on the worn surface concentric rings or portions of rings, between which they could distinguish concentric layers having a radiated striation. These concretions are constituted by oxamide and by an organic stratum, giving all the reactions of albuminoid substances. Treating these calculi by means of hot water at 176° to 194° F., the oxamide is dissolved and brings into view the organic stratum, sections of which offer a similar disposition to the worn surfaces, except that the suppression of these radiations reveals the relation which exists between these stellate fibres and the existence of oxamide.

DR. HANAU, of Zurich, read a paper on

THE ARTIFICIAL INOCULATION OF CANCER.

The experiments which have been undertaken up to the present in regard to the transplantation of cancer, have given in some cases absolutely negative results, in others inflammatory alterations of a simple form; sometimes a true clinical tumor has been observed, the carcinomatous nature of which, however, is questionable. Two experiments only—one of Nowinsky, the other of Wehr—can be considered as having been successful, and yet no histological examination has been made.

In November, 1888, Hanau transplanted into the tunica vaginalis of the testicle of two rats, materials derived from non-ulcerated glands, but which were already involved by metastasis from a cancroid of the vulva which had spontaneously appeared in a female. One of those rats died seven weeks later; the post-mortem showed the presence of nodular cancer occupying the whole peritoneum; for we know that in the rat the inguinal canal is not obliterated.

In a second rat, sacrificed at the end of the eighth week, the tail of the epididymis was the seat of a cancerous nodule of about the size of a pea, and the gubernaculum testis presented a nodule about one-thirtieth of an inch in diameter.

On histological examination, the identity between the structure of the tumors found in those animals and that of the cancerous material used was most striking. Both

cases were of squamous epithelioma. The absence of any primary cutaneous cancer in those animals previous to his experiment, and the localization of the cancroid on the surface of the peritoneum or tunica vaginalis, allow him to establish a certain relation between the fact of transplantation and the production of the cancer. The failure of former experiments must be attributed to bad manipulation.

From the second dead rat, cancerous material was obtained and transplanted to a third animal, in which the existence of a tumor can already be distinguished.

EXTIRPATION OF THE LARYNX FOR CANCER.

DR. ROSER, of Hanau, presented a woman, forty-five years of age, upon whom he had made a total extirpation of the larynx. The patient consulted him, for the first time, four years ago, when she presented a squamous epithelioma of the larynx.

Supra-sternal tracheotomy was first performed, which enabled the patient to go about for these four years, but six weeks ago, the patient having become suddenly worse, he decided to extirpate the vocal organ. The operation was a success, and the patient was presented to the members of the Congress. She is now being nourished with the aid of an œsophageal tube.

PROF. VON ZIEMSSEN then read a paper

ON CARDIAC CONTRACTIONS.

He has studied through the medium of tracings the successive phases of a cardiac cycle. Between the moment of complete rest in the state of diastole and the first cardiac sound, contraction is represented by a rapidly rising curve, soon followed by another rising curve nearly straight, but a little longer and approximating more to the horizontal line. Between the first and second sounds the cardiac tracing presents an almost vertical ascending line, terminated by a rounded hook, the summit of which corresponds to the phase of most active contraction; then the curve comes down again as suddenly to a level a little higher than the one corresponding to the beginning of the second phase; the curve then rises again at two different moments, but very feebly; and of these two summits, much lower than the first and corresponding to a normal dicrotism, the last one is the least elevated and corresponds to the second sound. Next the curve comes down somewhat less suddenly to the inferior level of the tracing, the total of which represents the whole cardiac cycle.

The experiments made with alcohol on the one side and digitalis on the other, show that, in the second case, the time elapsing between the phases of complete diastole and the first valvular sound is about the only one at all influenced; it is shortened in the first case, elongated in the second. These phases are in the proportion of 0.18 to 0.46, the normal phase being 0.25. The other parts of these tracings do not vary from the normal type.

DR. KREHL, of LEIPZIG, then spoke of the

VARIATIONS OF PRESSURE IN THE CARDIAC AND ARTERIAL CAVITIES.

At the Physiological Institute of Leipzig he made, with Prof. Frey, experiments on the dog by means of sounds introduced into the left ventricle and aorta, and of a rubber manometer which furnished a graphic variation of the blood-pressure in the left heart and aorta. In the heart the pressure rises rapidly, to come down to zero after having reached its maximum point. To the period of negative pressure succeeds immediately, after each cardiac beat, a positive pressure or a moment of rest. The absolute increase in the pressure rises in direct proportion to the degree of fulness of the heart, as well as in proportion to the amount of resistance. The closure of the valves is not marked very plainly on the tracing of the ventricular pressure. The elevation of pressure is more retarded at the base of the aorta than in the ventricle; the pressure rises as long as the outflow of the orifices is greater than the quantity which passes through the aortic opening. The aortic valves close as soon as the aortic pressure is superior to the intra-ventricular pressure; then we note a second maximum value of pressure, which constitutes the dicrotic character of the blood column, which is nearly always constant.

The dicrotic undulation is produced before the closure of the aortic valves; so that the production of this dicrotic undulation cannot be in direct relation to the closure of the aortic valves, and cannot be attributed to it. In comparing the variation of pressure in two different parts of the aorta, we find that this dicrotic undulation is always nearer to the heart. The dicrotic undulation being, then, an undulation, which from the periphery goes toward the centre, we understand that the greater the pressure the more will this tracing approximate to the principal summit of the tracing, for the rapidity of propagation of the undulation in the vascular channels rises in proportion to the tension of the walls. By means of stimulating the pneumogastric, one can produce aortic pulsations without dicrotism; this is what we observe when the reflected undulation comes back to the base of the heart, when the heart has stopped from emptying itself. If the pressure is not of an abnormal height, this phenomenon can still take place when, under the influence of the irritation of the pneumogastric, the graphic segment corresponding to the positive pressure of the ventricle finds itself prolonged.

DR. FR. MULLER, of Berlin, then read a communication

ON NUTRITIVE CHANGES IN CANCEROUS PATIENTS.

A careful examination of numerous experiments he had made to study the state of nutrition in persons suffering from cancer, has shown such a diminution in the excretion of urea, that one might have thought of the existence of renal complications. Toward the end of the disease, the comatose stage, in which many patients die, seems to be due to a real intoxication resulting from the accumulation of the organic waste material, which shows itself in the urine by the almost entire absence of urea. This fact might help us to explain the comatose state which often accompanies the death of the cancerous patient; this coma is a uræmic coma, and yet is remarkable on account of the absence of all renal lesions.

PROF. LEYDEN, of Berlin, stated that the researches relating to the nutrition of patients suffering from carcinoma or malignant tumors are of considerable practical importance. The works of Klemperer, Müller, and Freund allow us to find out the ways by which cachexia brings on death, and to discover at the same time the way in which rational therapeutics will be able to neutralize these destructive processes. From their researches

we shall obtain principles applicable to an internal medication appropriate to cancerous patients; without going so far as to pretend to cure cancer, we can declare, according to these researches, that the attempts of medicine to prolong the life of our patient will no more be restricted to the chances of purely empirical means, and that we possess to-day a new direction toward which we are to conduct therapeutical experiments. The use of the tube in many cancerous patients has enabled us to prolong the life and obtain a rapid increase in the bodily weight, favoring the organic nutrition. So long as nutrition will not be interfered with, either by the fact of a pyloric or intestinal stenosis, or so long as the intensity of the suffering does not go beyond human endurance, we shall be able to rely upon the favorable results of a nutritive course based upon pathologico-physiological researches, to postpone the period of cachectization and to prolong life.

DR. FREUND, of Vienna, had also studied from a chemical point of view the relations which exist between the different groups of albuminoid, mucous, fatty, hydrocarbonaceous, aqueous, and saline substances, in normal tissues as well as in those of malignant character. Out of sixty cases which he had studied in a period of three years, he had always found that those tissues of neoformation contain 50 per cent. less albumin than the normal tissues, and that carcinoma presented, with a normal proportion of fat, twenty or thirty times more hydrocarbons, while sarcoma presented about a normal proportion of fat and hydrocarbons, but an average of about 5 per cent. of the weight of the dry residue was peptone. On the other hand, the blood of cancerous patients, even at the beginning of the disease and outside of all cachexia, presented a proportion of sugar and hydrocarbons about double or three times the normal amount, while the blood of sarcoma did not contain any hydrocarbons in excess, but furnished an exaggerated proportion of peptone (0.2 per cent.). In such proportions both these substances must be considered as abnormal in the blood, their presence being attributable to a diminution of the oxidizing power of the tissues in regard to a special group of substances. It is interesting to note that the substances which are found in exaggerated proportion in the blood are precisely those which constitute an important element of each of these products of neoformation.

DR. FINKLER, of Bonn, the read a paper on

PNEUMONIA WITH STREPTOCOCCI.

He had observed, some time ago, a short epidemic of pneumonia, which suddenly appeared in the suburbs of Bonn; it was a pneumonia of lobular form, becoming lobar by propagation, and presenting the form known as erysipelatous or migratory pneumonia. The bacteriological researches, before and after death, have always invariably shown the presence of the same microörganism, the streptococcus pyogenes. The lung, however, did not suppurate, excepting a few small miliary abscesses, occupying in one case only the periphery of the involved lobule. These pneumonias occurring spontaneously in persons having not had before an infectious disease, having long ago passed the age of eruptive fevers, or, at least, having not had any before the pneumonia, proves that the streptococcus, the function of which is so important in the pathogeny of secondary infections, can primarily, and by its sole existence, determine pulmonary lesions the clinical and anatomo-pathological aspect of which leave no doubt as to its nature. This was the type of lobular, pseudo-lobar, or migratory pneumonia which he had observed.

DR. VON BASCH, of Vienna, then read a paper

ON CARDIAC DYSPNŒA.

His last experiments, which had been made, he said, with MM. Bettelheim, Grossmann, and Schronburg, confirm the theory of cardiac dyspnœa which he had framed some time ago. It is characterized by three phenomena: First, the dyspnœic type of respiration; secondly, the diminution, in the point of view of hematosis, of the respiration; thirdly, an increase in volume of the lungs. The last two phenomena are verified by means of percussion or spirometry. In cardiac dyspnœa, in the dog as well as in man, the increase in volume of the lung is due to insufficiency of the cardiac activity and to a consecutive repletion of the pulmonary bloodvessels; and, consequently, differs from the dyspnœa resulting from insufficiency of the right ventricle and of the consecutive anæmia of the lung, as in this last case the volume of the lung is reduced. Repeated experiments on dogs, in which the vagus had been previously cut, have established the fact that the increase or diminution in size of the lung is not due to peripheral irritation of the pneumogastric. On the other hand, the study of the thoracic pressure has demonstrated that the intra-thoracic pressure increases in the dyspnœa dependent on insufficiency of the left ventricle, and that it is in direct relation to the increase in volume of the lung, which is, consequently, passive.

The intra-thoracic pressure is, on the contrary, diminished in the dyspnœa due to insufficiency of the right ventricle, and is in relation with a diminution of volume of the thorax, which so constitutes an active phenomenon in cases of pulmonary anæmia. In the first case, the increase in volume of the lungs is due to a state of "pulmonary erection" which he described two years ago; while, in the second case, the diminution in the spirometric value results from the state of rigidity of the lungs, the existence of which can be discoverable on curarized animals.

As to the muscular effort, it brings on cardiac dyspnœa only after having produced a state of hyperpnœa; then an insufficiency of the left ventricle, which is accompanied by a state of pulmonary rigidity from which results a difficulty of ventilation.

In cases of cardiac asthma, dyspnœa also occurs when insufficiency of the left ventricle is established, and the prodromic dyspnœa must be attributed to an increase in volume of the lung, which shows itself by a state of tumefaction and rigidity of this organ.

DR. LEO, of Berlin, then read a paper

ON MOLECULAR CHANGES IN DIABETES MELLITUS.

He had made a series of researches on the nutritive changes in diabetic patients. These experiments have demonstrated that the quantity of oxygen which is absorbed and the quantity of carbonic acid which is eliminated are not identical in diabetic patients with the quantities of these same gases which are absorbed or eliminated by normal individuals. The contradictory results obtained by Pettenkofer and Voit, are due to the

fact that they failed to take into consideration the muscular effort, which is much less pronounced in diabetic, run-down patients than in healthy individuals. As to Ebstein's theory of the *rôle* of carbonic acid in diabetes, he did not think it sufficient. On giving carbonic acid inhalations to several diabetic patients, he noticed that the elimination of the sugar was not interfered with.

PROF. M. EBSTEIN, of Gottingen, said that if a diminution of carbonic acid proves that the tissues form less carbonic acid, the normal or increased elimination of the same acid does not imply that the production of carbonic acid in the tissues is not normal; it might even be diminished. On the other hand, the increase of the carbonic acid in the tissues, by inhalation of a large quantity of this acid, could not be compared to the action produced by the accumulation in the tissues of carbonic acid in a nascent state. The experiments of Leo do not demonstrate the hypothesis which he defends; for either the formed sugar is directly rejected, or else it deposits itself under the form of glycogen amidst the tissues; if this second supposition be a correct one, it would prove that when we increase the hydrocarbons of the organism, the saccharifying ferment has lost all power.

DR. DEHIO, of Dorpat, then spoke

ON THE PRODUCTION OF THE VESICULAR MURMUR.

The vesicular murmur, according to Betzold and other authors, was nothing but the tracheal or glottic sound, propagated throughout the pulmonary parenchyma. In laryngeal stenosis, however, even accompanied by great laryngeal noise, the vesicular murmur can be well heard. His starting-point having been that the vesicular murmur is not a propagated sound from the larynx, he made a series of experiments on artificially prepared lungs. The trachea was replaced by a large rubber tube and the lung inflated while he auscultated. Notwithstanding the absence of the trachea and the impossibility of any sonorous transmission, one hears very distinctly in prepared lungs the characteristic sound known as vesicular murmur. This vesicular murmur is, then, a sound having its origin in the pulmonary alveolus itself; and can be due only to the movement communicated by the inspired air column to the quantity of air which normally remains in the lung—the residual air.

(*To be concluded.*)

NEWS ITEMS.

The Third Annual Meeting of the American Association of Genito-Urinary Surgeons will be held at the Aquidneck House, Newport, on Tuesday and Wednesday next, May 21st and 22d, under the presidency of Dr. R. W. Taylor, of New York. The following papers are announced on the programme:

"The Question of the Radical Cure of Deep Urethral Stricture," by E. L. Keyes, M.D., of New York.

"The Essential Factor in the Etiology of Stricture and Its Bearing on the Question of Radical Cure, by John P. Bryson, M.D., of St. Louis.

"Cases of Nephrectomy and Nephrotomy," by R. B. Nall, M.D., of Memphis.

"A Contribution to Renal Surgery," by Nicholas Senn, M.D., of Chicago.

"Primary Syphilitic Lesions at the Meatus Urinarius," by Francis B. Greenough, M.D., of Boston.

"Induration of Venereal Sores not always an Indication that Constitutional Syphilis will Follow," by Edwin C. Burnett, M.D., of St. Louis.

"Malignant Tumors of Inguinal Ganglia Secondary to Epithelioma of the Penis," by Robert W. Taylor, M.D., of New York.

"The Relation of the Prostate to Chronic Urethral Discharge," by J. William White, M.D., of Philadelphia.

"Report of Three Cases of Chronic Cystitis of the Neck, resulting in the Formation of Hard, Fibrous Rings at the Site of the Sphincter Vesicæ; with Remarks," by John P. Bryson, M.D., of St. Louis.

"A Case of Melanotic Sarcoma of the Vulva," by Robert W. Taylor, M.D., of New York.

"Reflex Irritations from Stricture of the Urethra in the Female," by Fessenden N. Otis, M.D., of New York.

"Treatment of Gonorrhœa and Gonorrhœal Cystitis," by Edward R. Palmer, M.D., of Louisville.

"Cases," by Alexander W. Stein, M.D., of New York.

"Cases of Suprapubic Cystotomy," by L. Bolton Bangs, M.D., of New York.

"A Case of Scirrhus of the Bladder," by Arthur T. Cabot, M.D., of Boston.

"Hereditary Syphilitic Transmission Through Two Generations," by E. E. King, M.D., of Toronto.

"A Case of Poisoning by Chromic Acid, following its Application to Condylomata Acuminata," by J. William White, M.D., of Philadelphia.

"An Unusual Form of Vesical Calculus," by George Chismore, M.D., of San Francisco.

German Surgical Congress.—The Congress of German Surgeons, which held its eighteenth meeting this year, brought together nearly all the well-known workers of Germany, besides many from abroad. Among the latter a particularly hearty welcome was given to Billroth, of Vienna, who is an honorary member of the Society, but who has been absent from its meetings for several years owing to ill health. Professor Horsley, whose labors have been followed with equal interest by the physicians and surgeons of Germany, was the object of much attention.

The Congress was opened on April 24th with an address by the president, Professor von Bergmann. Referring to the sad April days of last year, which witnessed the sore struggle of the Emperor Frederick with his terrible disease, the speaker expressed a hope that, by steadfast adherence to what has once for all been recognized as true, there might some day spring from the seed of sorrow and suffering a blessed fruit for all, whether high or low, who trust to medical art.

It is impossible to furnish even a concise review of the abundant material presented at the sittings. The demonstrations of Professor Horsley (which were given in Dr. Dubois-Reymond's Physiological Institute, under the presidency of that gentleman) filled the theatre, and were received with loud applause. The same was the case with respect to an address by the Japanese physician, Dr. Kitassato, who, under the direction of Privy Councillor Robert Koch, has succeeded in obtaining pure cultures of the bacilli of tetanus.

The Congress held seven sittings under the presidency of Dr. von Bergmann. The presidentship for next year was on the afternoon of the third day again conferred on Professor von Bergmann. The close of the Congress

took place on the afternoon of April 27th.—*The British Medical Journal*, May 4, 1888.

Mind Cure only extreme Homœopathy.—The homœopathic doctrine of increasing potency with increasing attenuation has been ingeniously applied by the professors of the mind cure to their science, and one of them explains the working of their treatment as follows: "I have found, by actual experiment, that as the drug is attenuated its power is increased, until, when the drug is all gone and there is only mind, its greatest efficacy is reached."—*North-Western Lancet.*

A Powder for Sore Feet.—From Germany comes a bit of valuable information for policemen, carriers, collectors, and others, whose occupation requires them to be on their feet a great deal. No matter how comfortable or roomy their shoes, such persons are almost always more or less troubled with chafed, sore, or blistered feet. The difficulty may be readily overcome by the use of a powder, which is a necessary part of the German army equipment. It is known there as "Fussstreupulver," and consists of three parts of salicylic acid, ten parts starch, and eighty-seven parts pulverized soapstone. It keeps the feet dry, quickly heals sore spots, and prevents chafing. A powder of pulverized soapstone is also good.—*American Druggist*, April, 1889.

Corrigendum.

We are requested to state that the honorary degree of Doctor of Medicine conferred upon Dr. J. S. Billings came from the University at Munich, and not from that of Vienna.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 7 TO MAY 13, 1889.

By direction of the Acting Secretary of War, a Board of Medical Officers, to consist of: ANTHONY HEGER, *Lieutenant Colonel and Surgeon;* F. C. AINSWORTH, *Captain and Assistant Surgeon;* and JOHN O. SKINNER, *Captain and Assistant Surgeon*, will assemble at the U. S. Military Academy, West Point, New York, on June 1, 1889, to examine into the physical qualifications of candidates for admission and members of the graduating class. —Par. 9, *S. O. 108, A. G. O.*, May 10, 1889.

By direction of the Acting Secretary of War, F. C. AINSWORTH, *Captain and Assistant Surgeon*, will proceed to Albany, New York, on business connected with the Medical Department.—Par. 7, *S. O. 105, A. G. O.*, May 7, 1889.

APPEL, D. M., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Sill, Indian Territory, and ordered to Fort Bliss, Texas.—Par. 25, *S. O. 104, A. G. O., Washington*, May 6, 1889.

COWDREY, S. G., *Captain and Assistant Surgeon* —Relieved from duty at Fort Bliss, Texas, and ordered to Fort Marcy, New Mexico Territory.—Par. 25, *S. O. 104, A. G. O., Washington*, May 6, 1889.

FINLEY, JAMES A., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Assinniboine, Montana Territory, and ordered to Fort Totten, Dakota.—Par. 25, *S. O. 104, A. G. O., Washington*, May 6, 1889.

DE LOFFNE, AUG. A., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Totten, Dakota, and ordered to Columbus Barracks, Ohio.—Par. 25, *S. O. 104, A. G. O., Washington*, May 6, 1889.

TAYLOR, B. D., *Captain and Assistant Surgeon.*—Relieved from duty at Columbus Barracks, Ohio, and ordered to Fort Sill, Indian Territory.—Par. 25, *S. O. 104, A. G. O., Washington*, May 6, 1889.

By direction of the Secretary of War, PAUL R. BROWN, *Captain and Assistant Surgeon*, is relieved from further duty in the Department of the Platte, and will proceed to Fort Thomas, Arizona Territory, and report in person to the commanding officer of that post for duty, and by letter to the commanding officer Department of Arizona.—Par. 10, *S. O. 105, A. G. O*, May 7, 1889.

By direction of the Acting Secretary of War, the ordinary leave of absence granted WILLIAM B DAVIS, *Captain and Assistant Surgeon*, in Special Orders No. 232. October 5, 1888, from this office, is extended six months, on surgeon's certificate of disability. —Par. 20, *S. O. 108, A. G. O.*, May 10, 1889.

By direction of the Acting Secretary of War, WILLIAM P. KENDALL, *First Lieutenant and Assistant Surgeon*, will be relieved from duty in the Department of California, after he shall have complied with the requirements of Par. 2, S. O. 29, April 24, 1889, from these headquarters, and will then proceed to Fort D. A. Russell, Wyoming Territory, for duty at that station.—Par. 28, *S. O. 104, A. G. O.*, May 6, 1889.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY, FOR THE TWO WEEKS ENDING MAY 11, 1889.

BEARDSLEY, GROVE S., *Medical Inspector.*—Detached from the "Brooklyn," proceed home, and wait orders.

LOVERING, P. A., *Passed Assistant Surgeon.*—Detached from the "Brooklyn," proceed home, and wait orders.

NORTON, OLIVER D., *Assistant Surgeon.*—Detached from the "Brooklyn," proceed home, and wait orders.

HAWKE, J. A., *Surgeon.*—Detached from the "Essex," proceed home, and wait orders.

STOKES, C. F., *Assistant Surgeon.*—Detached from the "Minnesota," and ordered to the "Iroquois."

BRANSFORD, JOHN F., *Surgeon.*—Orders to the "Iroquois" revoked. Resignation accepted, to take effect May 4, 1890, with leave of absence granted to that date, with permission to leave the United States.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE FOUR WEEKS ENDING MAY 11, 1889.

PURVIANCE, GEORGE, *Surgeon.*—Detailed as Chairman of the Board for the Physical Examination of Candidates for Appointment as Cadets, Revenue Marine Service, May 3, 1889. Detailed as Chairman of Board for the Physical Examination of Officers, Revenue Marine Service, May 11, 1889.

IRWIN, FAIRFAX, *Surgeon.*—To proceed to Bath, Wicasset, Rockland, Belfast, Bangor, Ellsworth, Machias, and Eastport, Maine, as Inspector, April 22, 1889.

MEAD, F. W., *Passed Assistant Surgeon.*—Detailed as Recorder of the Board for the Physical Examination of Candidates for Appointment as Cadets, Revenue Marine Service, May 3, 1889 Detailed as Recorder of the Board for the Physical Examination of Officers, Revenue Marine Service, May 11, 1889.

WHEELER, W. A., *Passed Assistant Surgeon.*—Granted leave of absence for thirty days, April 16, 1889.

BRATTON, W. D., *Passed Assistant Surgeon.*—Relieved from duty at San Francisco, California, to assume charge of the Service at Portland, Oregon, May 8, 1889.

MAGRUDER, G. M., *Assistant Surgeon.*—To proceed to Baltimore, Maryland, for duty, May 8, 1889.

PERRY, T. B., *Assistant Surgeon.*—When relieved at Portland, Oregon, to proceed to San Francisco, California, and await orders. May 8, 1889. To report to the commanding officer Revenue Steamer "Rush," for special duty, May 11, 1889.

CONDICT, A. W., *Assistant Surgeon.*—When relieved from duty at Boston, Massachusetts, to await orders, May 8, 1889. To report to the commanding officer Revenue Steamer "Chase," for special duty, May 11, 1889.

HUSSEY, S. H., *Assistant Surgeon.*—When relieved from duty at Baltimore, Maryland, to proceed to Boston, Massachusetts, for duty, May 8, 1889.

GEDDINGS, H. D., *Assistant Surgeon* —To proceed to Baltimore, Maryland, for temporary duty, May 8, 1889.

ORIGINAL ARTICLES.

DIGITAL DIVULSION OF THE PYLORUS FOR CICATRICIAL STENOSIS.[1]

BY J. M. BARTON, A.M., M.D.,
SURGEON TO THE JEFFERSON COLLEGE HOSPITAL, PHILADELPHIA.

DIGITAL divulsion of the pylorus for cicatricial stenosis as first practised by Prof. Loreta, of Bologna, Italy, in 1882, has scarcely received the attention which it deserves anywhere, except in Italy.

The mortality from the twenty-five operations which the author succeeded in collecting is not great, when we consider that every successful case is a patient rescued from certain, and by no means distant, death, and this mortality is already decreasing.

The cases in which the operation would be of service are not so very rare. When searching the journals for records of such operations I found the reports of the presentation of many specimens of cicatricial stenosis of the pylorus to various pathological societies. My own experience has been limited to two operations. Even the first, though it proved fatal on the fourth day, encouraged me to operate again, as I was fully satisfied that had it been performed earlier, when the patient was stronger, there was no reason why it should not have been successful.

My second case had the following history:

Mrs. G., aged forty-eight years, a patient of Dr. Adams, of Vineland, N. J., was first seen by me at her home, near Vineland, in December, 1888. For convenience of study and operation I admitted her to Jefferson College Hospital in January, 1889. During 1884, 1885, and 1886 she had suffered from gastric ulcer. She had pain and vomiting immediately after eating, the vomiting occurring as many as six times in the twenty-four hours; she lost greatly in weight and had two severe hemorrhages. In 1887 all of the symptoms left her and for the greater part of the year she enjoyed excellent health, weighing in January, 1888, one hundred and forty-three pounds, which was more than she had ever weighed in all her life. During 1888 she became very ill with symptoms of pyloric obstruction and lost flesh rapidly, weighing after her admission to the hospital, only ninety-three and one-half pounds. She then vomited but once in twenty-four or forty-eight hours. This occurred when she laid down at night and was not accompanied by nausea. It was usually from one and a half to two quarts in quantity and measured nearly and sometimes quite as much as all the nourishment taken since the preceding act of vomiting, twenty-four hours before. Many articles taken during the day could be recognized; indeed, she stated that she had occasionally been able to recognize articles eaten as long as two weeks before. As she took her meals she felt that the stomach was becoming more and more distended and when she laid down at night, gravity brought the contents of her stomach into her throat and they were then vomited. Her bowels were obstinately constipated, acting only once in twelve or fourteen days, and then only after frequently repeated large injections; purgatives administered by the mouth producing no effect. She had lately been able to feel occasionally a small tumor about the size of a hazel-nut, two inches to the right of the umbilicus and situated quite deeply. Her stomach was greatly enlarged; distended by the carbonic acid gas developed from half of a soda powder, it reached as low as the umbilicus and as far as the small tumor, though we could not say that the tumor was connected with the stomach.

The vomited matters separated themselves into the usual three layers, the middle one being quite clear. They were nearly free from undigested food and not offensive; free hydrochloric acid, though searched for, was not found.

The operation was performed in the presence of the class of Jefferson Medical College, February 16, 1889. The surface of the abdomen had been prepared the day before, the mercurial dressing being still on when the patient was brought into the amphitheatre. Her stomach had been washed out on the morning of the operation with a solution of biborate of soda. This had been repeated until the fluid returned quite clear. Chloroform was used as the anæsthetic in preference to ether, as being less apt to be followed by vomiting. The hands and instruments having been prepared with antiseptic solutions, I made a median incision through the skin, about four inches long, terminating at the umbilicus. The peritoneal incision, however, was only three inches in length. There was but little bleeding and it was readily controlled by clamp forceps.

The dilated stomach sac was found directly beneath the incision. The junction of the stomach and duodenum, even from the outside, was markedly contracted and irregular on its surface. There were no adhesions and there was no tumor. The tumor was found to be a hard scybalous mass in the ascending colon which also contained quite a number of smaller masses of hardened fæces. As the wall of the stomach, three inches from the pylorus, felt quite healthy, I folded it transversely midway between the greater and lesser curvatures, and with a

[1] Read before the American Surgical Association, May 15, 1889.

pair of sharp scissors made an incision between one and a half and two inches in length. There was no bleeding requiring attention. I introduced my index finger through this incision and felt the pylorus, contracted to about the size of a No. 10 French catheter; its margins were quite hard and fibrous. As the fingers would not enter, the blades of a small uterine dilator were guided by the finger into the contracted pylorus, which was then readily dilated until it admitted the index finger. With the aid of a pair of œsophageal forceps it was still further dilated until both the index and middle fingers were admitted. The two fingers were then separated about half an inch, when I ceased, feeling that further effort would probably rupture the mucous membrane. This dilatation gave to the pylorus a circumference of four and one-half inches.

The mucous membrane of the stomach at the point of incision was brought together by a continuous silk suture, and the serous coat by a continuous Lembert suture also of fine silk carried in an ordinary sewing needle. This suture was introduced deeply into the muscular coat in order to obtain a firm hold; even then it tore out at one or two points, requiring an interrupted suture to be used at those places. When the finger was first introduced into the stomach it caused some retching, forcing most of the stomach out of the wound, where it was kept during the subsequent manipulations. After the wound in the stomach was closed the organ was carefully sponged and restored to the abdominal cavity. The abdominal wound was then closed and dressed in the usual manner.

The patient vomited about four ounces of blood half an hour after the operation, but there have been no nausea and no vomiting since. She was nourished exclusively by the rectum until the fourth day. From that time until the fourteenth day she was fed upon peptonized milk and animal broths. After the seventh day she took from forty-eight to sixty ounces of liquid nourishment in the twenty-four hours. Some solid food was given on the tenth day, and after the fourteenth day she was fed upon a carefully selected solid diet. On the thirtieth day after the operation she was able to eat eggs, mutton chops, oysters, beef, chicken, lamb, potatoes, cream, toast, bread and butter, milk, and coffee. Her temperature has never been over 99° F., nor under 98° F., since the operation. Her bowels act naturally every day. The abdominal stitches were removed on the ninth day. On February 8th, before the operation, she weighed 93½ pounds; March 25th, she weighed 110 pounds; April 15th, 118 pounds; and April 27th, 122 pounds. She was able to leave the hospital April 10th. She had no pain at any time, and required no anodynes.

I have succeeded in collecting twenty-five published operations; many of these are by Prof. Loreta. I had hoped to have obtained the results in all his cases, but Dr. Peruzzi, his chief assistant, replies to a letter of inquiry, that the Professor has performed in all about 30 operations, and that at least six more have been performed by other Italian surgeons. They were all successful when the diagnosis was correct. This would make the total number of operations about 43. The 25 operations included in my list were performed on 24 patients, one patient having been operated on twice successfully by Prof. Loreta. From the 25 operations there were 15 recoveries and 10 deaths, making a mortality rate of 40 per cent. Of the 10 deaths, 6 were due to shock, 2 to hemorrhage, 1 to tetanus, and 1 to suppression of urine. The large mortality from shock in an abdominal section performed in from half an hour to an hour is probably due to the fact that in this, as in most new surgical procedures, the operation is postponed too long. The mortality is already decreasing. Of the first 12 cases reported, 6 recovered and 6 died; while of the last 12, 9 recovered and 3 died. This mortality can, perhaps, be still further lessened by earlier diagnosis and operation, and by such methods of operation as are most quickly performed and accompanied by the minimum loss of blood.

DIAGNOSIS.—The diagnosis can be conveniently divided into two parts: 1. To determine the existence of pyloric obstruction; and, 2. To differentiate between obstruction caused by cancer and that caused by cicatricial stenosis. But few of the reported cases have such a typical history as the one I have related. The coexistence of dyspeptic symptoms, or of some still open ulcers, complicated the diagnosis in most of the cases. I should regard as of little value some of the symptoms upon which much stress has been laid. The material vomited in some cases consisted of partly digested food; in some it was wholly undigested and offensive; while in others it consisted of well-elaborated chyme. The character of the material indicates the health and physiological activity of the stomach, but throws little light upon the condition of the pylorus. In some cases sarcinæ were present, but in many they were absent. The same may be said of starch granules, of needles of the fatty acids, of free hydrochloric acid, of pain, and of other dyspeptic symptoms which have usually existed for many years before the symptoms of obstruction occurred.

The following symptoms I would consider of value: 1. A greatly dilated stomach. 2. The vomiting of from one to two quarts of material at one time. 3. The recognition in the vomited matter of articles that have been taken many hours, days, or weeks before. 4. When the act of vomiting is performed with great ease, without nausea, and the appetite is good immediately afterward. 5. Obstinate constipation. 6. The non-effect of ordinary purgatives. 7. A preceding history of gastric ulcer of several years' duration, and temporary improvement followed by simple obstructive vomiting of well-elaborated chyme many hours after taking food. This typical history occurred but twice among the twenty-four cases. Where the symptoms are obscure,

great reliance may be placed upon the detection of a decidedly enlarged stomach, as this is rare, except as a result of mechanical obstruction of the pylorus.

The mere presence of tumor is almost without value in the differential diagnosis between cancer and stenosis. In the 24 cases, tumor was present in 7, absent in 4, and not noted in 13. A rapidly growing, nodulated tumor low down in the abdomen is probably malignant. A poorly-defined tumor, not increasing in size, high in the abdominal cavity, is probably non-malignant. The average duration of cancer of the pylorus is one year (Brinton). The maximum duration, three years (Bartholow). The average duration of the gastric symptoms in 13 of the 24 cases in which this was noted was eleven years. The history of temporary improvement is against malignant disease. In the later stages of cancer, the obstruction is often removed by ulceration, and diarrhœa occurs. In the later stages of ulcer the obstruction increases, and the stenosis is more obstinate.

THE ABDOMINAL INCISION.—In all of the reported cases, but two methods of opening the abdomen have been used. One by an incision running from one inch below the ensiform cartilage to the extremity of the ninth rib on the right side, a distance of

[1] Letter to Dr. Harris stating that to November 30, 1888, he had had 9 cases, of which 5 were cured and 4 died, 3 from shock, and one from hemorrhage.

about six inches; the other, by an incision in the median line, between the ensiform cartilage and umbilicus, and from three to six inches in length. The first method was used by Loreta in his earlier cases, but he now uses the latter exclusively.

The stomach wound should be made far enough from the pylorus to be in healthy tissue. If some inches from the pylorus, it will be outside the zone of inflammation following the dilatation. Experimenting upon cadavers, I found that separation of my fingers more than an inch caused rupture of the mucous membrane.

The stomach wound has been closed in many ways, and all did well. In no case was there the slightest leakage. No case suffered from peritonitis, and in none was the stomach wound the cause of death. I would suggest that probably the best method would be a continuous suture of catgut to the mucous membrane and the suture of Appolito to the peritoneum.

Diet.—In some of the reported cases food has been given as early as a few hours after the operation, without injury. I delayed until the fourth day, although I see no reason why food should not be given earlier. Peptonized milk, animal broths, diluted wines, and the yolks of eggs would be the best articles, according to the condition of the stomach prior to operation. Rectal alimentation will be required until sufficient food can be given by the mouth. Solid food has rarely been given before the tenth day, and then sparingly.

Permanency of Cure.—Recontraction of the cicatricial tissue would naturally be feared, but Loreta, in January, 1885, nearly three years after his first operation, writes: "I have now operated on six cases. They all have recovered, and all remain well up to the present time." Haggard, in 1888, reports that the case he operated on two years before was "still perfectly well, no vomiting, dilatation of stomach less, and she has recently married." Peruzzi in his letter to me, March 22, 1889, states that he knows of only one relapse among the thirty cases upon which Prof. Loreta has operated. This patient was reoperated upon, recovered, and remained well.

In four of the fatal cases included in the list the obstruction was valvular, due to irregular contraction of the walls of the stomach. In another case, not included in the list, as the stomach was not opened, the valvular obstruction was caused by distortion produced by external adhesions. These were divided, and the patient made a good recovery. In another case not included in the list, the operator recognizing that he had badly ruptured the mucous membrane while stretching the pylorus, immediately performed pylorectomy, with recovery of the patient. In another case the obstruction was caused by an adherent pancreas. The cause of the adhesion was an ulcer starting in the posterior wall of the stomach and penetrating the pancreas. In this case, an incision about two inches in length was made from stomach to duodenum, passing through the pylorus. The two extremities of the wound were brought in contact and the wound sewn up at right angles to its position when made. When completed, it was parallel to the long axis of the body. This patient recovered after a serious illness.

PULMONARY CONSUMPTION A NEUROSIS.

By THOMAS J. MAYS, M.D.,
Professor of Diseases of the Chest in the Philadelphia Polyclinic and College for Graduates in Medicine.

The bacillus theory of pulmonary phthisis is accepted in some quarters as a self-evident truth. The reason for this cannot be positively and logically stated by even its most earnest devotees. If the bacillus is the cause of phthisis, then should our reasoning, based on the bacillus as such, be in harmony with the practical facts as they are found. It is not scientific to say that because a disease can be transmitted to the lower animals by inoculation that it is maintained in the same way in the human family under ordinary conditions. Cancer, and probably most diseases, are communicable in this manner, yet no one regards all such diseases as contagious.

We have learned from a long experience that there are certain well-defined general conditions to be fulfilled by a disease before it can be called contagious. These are (1) a protection of the individual against future attacks; and (2) an equal liability of all the unprotected, provided the same conditions obtain. In regard to the first prerequisite, it may be said that phthisis does not only not protect the individual, but really predisposes him to future attacks. Not only is this true of the individual, but all his descendants become more vulnerable to it. The very opposite holds true of smallpox and syphilis, which represent that class of diseases which are propagated from individual to individual, through a specific virus, under the ordinary conditions of life. These diseases not only protect the individual, but also lend a certain protective influence to his progeny—thus showing that the tendency of all true contagious diseases is toward an extinction of the disease, while in the case of pulmonary phthisis the leaning is toward an extermination of the individual and his offspring.

It is true, at least in some of the older cities of this country, that a slight diminution in the death-rate from consumption has taken place during recent years. This is not due, however, to any protection which the disease affords against future attacks, or to any precautionary measures which have been taken against bacillary infection, but entirely to the

fact that man, by a better acquaintance with the laws of preventive medicine—by improving the warming and ventilation of his dwelling and of his workshop, by avoiding overcrowded and damp habitations, by becoming more temperate in all things, and by living on good nutritious diet—has succeeded in establishing a greater harmony between himself and his environment, and has thus rendered himself less amenable to the disease.

In the second place, it may be stated that, so far as phthisis is concerned, there is no equal liability among those exposed to it. On the other hand, it is one of the most fastidious diseases in the selection of its victims. For example, no matter whether they are exposed or not, it may be foretold with a great deal of precision, that the youngest and then the oldest of a family are most prone to its attack. About three years ago I tabulated nearly five hundred cases of this disease, and found, as others had done before me, that this is the almost universal law. So, on the whole, the male is more liable than the female; the inactive more than the active; and those living near the sea level more than those living on the mountains. But the most positive proof that those exposed to the disease are not more liable to it than those not so exposed, are the statistics which have been collected in the Brompton Hospital for Consumption in London, during the thirty-six years which it had been in operation prior to 1882. During that period there were twenty-nine physicians and assistant physicians, and one hundred and fifty clinical assistants connected with the institution, and of all these, and of the one hundred and one nurses of which there is a health record, not a single case of phthisis could be traced to contagion, although six cases occurred among that number. That this exemption does not obtain, as is frequently asserted, in hospitals devoted to the treatment of infectious diseases, is well shown, at least so far as typhoid fever is concerned, in the records of the Massachusetts General and the Boston City Hospitals. In the former—from 1882 to 1887—no less than seven, and probably eleven; and in the latter—from 1884 to 1888—twenty-eight, cases of typhoid fever occurred among the medical attendants and employés.[1]

These and many other practical and incontrovertible facts oppose the contact theory of the origin of pulmonary phthisis, and naturally indicate that its existence must depend on other causes. Now what are these causes? In surveying the field of probability, it has appeared to me that the potentiality of disordered pneumogastric innervation to produce pulmonary disintegration has not received that degree of attention which is warranted by the facts. These nerves constitute the principal nerve supply of the lungs, and endow them with motion and special sensation. On *à priori* grounds one would think that a disturbance of their function might at least have some connection with the causation of phthisis; but, strange to say, the bacillus maelstrom has so completely swept everything before it, that no thought whatever is given to this phase of the problem. Now when we come to consider that disease of every cranial and of every spinal nerve is known to be followed by disease in the organs to which they are tributaries; that during recent years it has been found that peripheral nerve disease may exist independent of any central lesion; that this has thrown new light on many phenomena which were before supposed to be inexplicable; and that section of the vagi in animals is followed by inflammatory changes in the lungs, we may well ask if it is not incumbent on us as scientific men to ascertain whether or no the pneumogastric nerves share any responsibility in the evolution of pulmonary phthisis.

The influence of section of the vagi on the lungs has been studied by a great many observers, and it is known to be followed by death in rabbits within twenty-four hours, and in dogs within a week. The pathological changes which this operation calls forth have been compared by Traube, Mendelsohn, Barthez, Friedländer, and others to a broncho-pneumonia, and it is said that Schiff succeeded in developing yellow tubercles in the lungs of rabbits. In one of my own experiments, a series of which I have under way at present, and in which I slightly stretched the left vagus, and then wrapped it tightly with cotton saturated in glycerine, I found small yellow nodules under the pleura, which had all the appearances of yellow caseating tubercle in man. I do not relate this in the belief that all the characteristic lesions of phthisis can be produced in animals, but merely because it seems to confirm the findings of Schiff. The inflammation produced in this way is called "schluck" pneumonia, inasmuch as it is supposed to be due to the entrance of foreign particles, such as food, mucus, etc., into the windpipe on account of the paretic condition of the larynx. This does not seem to be true, however, for Arnsperger (*Virchow's Archiv*, vol. ix. pp. 197 and 437) has shown that if, after section of the nerves, a tube is inserted in the trachea, and the entrance of foreign bodies into the lungs is prevented, the same pulmonary changes occur.

At the present time, when almost every disease is traced to bacillary infection, it is interesting to know that this form of pneumonia contains microörganisms, which, on being inoculated, reproduces the disease in healthy animals. Thus Jens Schou (*Fortschritte der Medicin*, 1885, No. 15) found that in vagus-pneumonia an abundance of various bacteria

[1] Boston Medical and Surgical Journal, May 24, 1888, pp. 513 and 523.

were produced in the alveolar and pleural exudations. He isolated three varieties of bacteria, which he cultivated in proper media. The first was an elliptic coccus of medium size, which, on being injected directly through the thoracic walls into the lungs, or through the trachea, always generated a typical vagus-pneumonia. Culture fluids, which were sterilized before injection, always produced negative results. The other two were also cocci, of somewhat different shape from the first, but they were incapable of calling forth the same morbid process in the lungs. Friedländer's coccus could not be found. All the vagotomies were performed in a bloodless manner, under strict antiseptic precautions, and the animals were kept in clean cages and received no food.

These experiments certainly prove that vagus disintegration is followed by a pneumonia which produces certain kinds of microörganisms, which, on being introduced into healthy animals, reproduce the disease from which they originally sprang. This brings up the interesting question as to how far the same principle holds true in the artificial production of bacillary phthisis; and it also indicates the possibility that some more of our so-called infectious diseases, not dependent on microörganisms originally, may generate their characteristic bacteria, which, when introduced into the bodies of healthy animals, are capable of calling forth the original diseases.

That pulmonary consumption is either very closely related to, or possibly dependent on, the nervous system, has been present in my mind for a number of years, and in the fall of last year I embodied my views on this subject in two lectures[1] which I delivered at the Philadelphia Polyclinic, and in concluding which I said: "From the evidence which has thus been collected it appears that pulmonary consumption is certainly not a local disease; that it is essentially a neurosis of the peripheral nerves; that the neurosis in all probability establishes a herpes of the vagi, in the same manner as a similar affection is produced in the skin, which gradually leads to all the characteristic lesions of the disease; and finally we will no longer be forced to admit that the disease, originally diagnosed as pulmonary consumption, has been superseded, or is accompanied by paresis, dropsy, intercostal neuralgia, peripheral or multiple neuritis, herpes zoster, and a multiplicity of other diseases, if we accept the neurotic nature of this disease, which implies that all these complications are but the legitimate results, and that the lung affection is but one of the many manifestations of the fundamental disorder."

At this time I was not aware that this question had been approached in a similar way by any one else, but within a few days only I had the pleasure of finding that as far back as 1871,[1] under the heading of "Phthisis as a Neurosis," Dr. Clifford Allbutt discusses a variety of phthisis which, he holds, does does not agree with the general meaning of the term "phthisis." He says that patients belonging to this type of the disease come from the neurotic class, in illustration of which he cites the following cases which came under his observation:

"About a year ago I attended a refined lady belonging to a highly neurotic family, and whose children presented the like characters; she had been a nervous, irritable, neuralgic woman all her life, but never actually ill in any serious way. She was worn down by nursing one who was very dear to her, and whose death, which followed, shocked and prostrated her still more. She took to her bed with consolidation of the apex of the right lung, then of the left; in both the mischief spread rapidly, hectic fever ran high; in three weeks she was dead. Her age was forty-three. On the autopsy, which was made in consequence of her death appearing to her family to be very sudden, we could not find a single tubercle in the body; but the apices of the lungs were almost destroyed, and less degrees of mischief were found below.

I had seen another case, a few years before, in which such a galloping consumption had occurred after nervous depression in a highly neurotic subject. The son of nervous parents on both sides, the father being odd and eccentric, and the mother actually insane, he was himself one of those heady, impassionable, gay fellows who make our charming prodigals—and a very pretty prodigal he was. Ruined in purse and character, and terribly depressed, though I do not think in any great degree worn out by actual vice, he arrived at home to meet with the reception such parents (or, at any rate, one of them) were likely to give him. A few days later he began to feel more and more exhausted; his pulse and temperature ran up; his right lung solidified and broke down; the left lung followed; and after five weeks of distressing illness he was dead. This case was the first which impressed me strongly with its probable neurotic origin. . . . Having, then, cases of phthisis presenting the exact features already described, and having also many cases of catarrhal broncho-pneumonic phthisis, and, more strictly, tubercular phthisis, presenting like characters intercurrently with others of their own, I felt that neither the catarrhal nor the tubercular theory accounted for all instances . . . until I began to find, in my own practice and in the writings of alienists, how large a part phthisis plays in neurotic families. Even then, however, it did not occur to me to associate any particular form of phthisis with neurotic disorder, until a few striking cases of my unclassable variety occurred in neurotic families under circumstances which spoke too eloquently to be overlooked. . . . If we try to go a step further and ask for a pathological explanation of these facts, we approach a land of darkness. The more, however, I study the relations of the disease, the more I am satisfied that the lung mischief is also a neurosis; by which I mean that the lesion is one not originating in the local tissues, but in the nervous system."

Thus wrote a shrewd medical observer eighteen years ago, and how well he pictures an experience so familiar to most of those who have given studious attention to the details of this disease! and were he

[1] Pulmonary Consumption considered as a Neurosis. Therapeutic Gazette, November and December, 1888.

[1] The Medical Times and Gazette, 1871, vol. ii. p. 613.

to write under the advanced intellectual influence of the present day he would, I am quite sure, not limit his neurotic type of phthisis to that class of cases in which the nervous element predominates most obviously, but would include all that is implied under the term of chronic idiopathic pulmonary consumption.

As clearly as it has been impressed on my mind that pulmonary consumption is at its root a nervous disease, it has been a question as to the manner of demonstrating the truth of this belief to the best advantage. Several possible avenues presented themselves through which the question might be solved. First, by experiments on the vagi of animals; second, by the collection of cases of human phthisis in which vagus disturbance was the cause of the disease; and thus establish a literature of cases on the subject. After giving the former a thorough test I found it inadequate, because, for reasons which will appear further on, phthisis is evidently a disease not dependent on a transitory, but on a protracted and long-continued disorder of the vagi, and the regulation of the desired degree of irritation in the vagi of animals in order to produce the proper result is very difficult, if not impossible, to attain.

Having ascertained the shortcoming of the first method, I endeavored to find whether or no the second was a feasible one. At this time I did not know that so much practical evidence could be obtained to insure the success of the second method. But with the aid of the almost endless variety of material which is furnished by the library of the College of Physicians, I am glad to state that I am able to report one hundred and four clinical cases which demonstrate that disintegration of the vagi[1] leads to phthisis, pneumonia, bronchitis, œdema, and to other forms of pulmonary disease in the human subject. The reference to these cases are given only, and in the following order: (1) Those in which disintegration of the vagi produced disturbance of hunger and thirst; (2) those in which it produced suffocation, paralysis of respiration, or collapse of the lung; (3) those in which it produced pulmonary œdema; (4) those in which it produced hemorrhagic infarcts in the lungs and in the pleura; (5) those in which it produced bronchitis; (6) those in which it produced pneumonia; and (7) those in which it produced pulmonary consumption.

There were three cases[2] in which vagi disease disturbed hunger and thirst.

Six cases[3] in which vagi disintegration led to a sense of suffocation, paralysis of respiration, or collapse of the lungs.

Seven cases[1] in which vagus disintegration caused pulmonary œdema.

Four cases in which vagus[2] disintegration produced pulmonary infarcts.

Seven cases[3] in which vagus disintegration led to bronchitis.

Twenty-seven cases[4] in which vagus disease produced pneumonia.

Fifty-one cases[5] in which vagus disease produced pulmonary consumption.

[1] Some exceptions, which are noted further on.

I think the histories of these cases, among other things, give the most ample evidence that vagus disease not only leads to lung disintegration, but to that special form of disintegration known as pulmonary consumption. Of the 104 cases recorded, there is direct proof that in 84 the vagus disturbance was followed by lung disease, viz., in 6 by paralysis of respiration and lung collapse; in 6 by œdema; in 4 by infarcts; in 6 by bronchitis; in 25 by pneumonia; and in 37 by phthisis; while in the remainder of the cases the vagi were probably equally diseased, but were not examined, but in most of which it appears that the medulla oblongata, or some other point in the respiratory centre, was involved in the disease. Moreover, in the collection of my cases I found that the ganglion of the trunk of the vagus had been investigated *post-mortem* in 20 cases of pulmonary consumption, by Dr. A. Lewin (*Beiträge zur Pathologie der N. Vagus.* Dissertation, St. Petersburg) and in 11 cases of the pneumonia of paralytics, by Drs. Bianchi and Armandi (*Neurologisches Centralblatt*, 1888, p. 452), and it was found diseased in every instance. Hence, we have a definite record of 57 cases of phthisis, 36 cases of pneumonia, and 25 cases of other lung disease associated with vagus disease—besides 18 other similar affections concerning which there is a strong suspicion that they were due to the same lesion—or 136 cases in all. When we consider that no one, I believe, except Dr. Lewin, has investigated this question with a view of determining the relationship between vagus disease and phthisis, and found the association so constant, and that all my cases were collected from current medical literature, where they obtained incidental lodgement only, so to speak, leads one to believe that the two conditions are more intimately connected, one with the other, than is generally supposed.

These cases further show that phthisis is not a separate and independent disease specifically created by the tubercle bacillus, but that it is a condition which is slowly evolved out of other pulmonary disorders depending fundamentally on vagus disintegration. For in not a single instance was phthisis or even pneumonia produced by a sudden interference with the integrity of the vagi, as in division or in injury, but the devitalizing processes in both of these conditions was established either by a long-continued pressure on, or a slow disintegration of these nerves. So far as the character of the causes of vagus disintegration is concerned in my collection of cases, it may be said that in 94 these were distributed as follows: Neuroma, 3; atrophy and paralysis, 12; ligation, division, and other injury, 8; compression by enlarged glands, tumors, and aneurisms, 43; carcinoma, 7; and neuritis, 21.

These cases not only establish conclusively, then, that phthisis, pneumonia, and various other pulmonary affections are produced by long-continued pressure on the vagi, as by tumor, etc.; but that these diseases, and especially phthisis and pneumonia, are the result of a common degeneration of the vagi and the peripheral nerves, induced by the action of alcohol, syphilis, diphtheria, etc. Then, as further evidence of the implication of the peripheral nervous system in phthisis, we have the work of Dr. Jappa ("Zur Frage über die Veränderungen der peripherischen Nerven bie Schwindsucht," *Neurologisches Centralblatt*, Bd. 7, 1888, p. 425), which comprises the histological examination of the peripheral nerves in the bodies of fifteen persons who died of pulmonary tuberculosis. He investigated the sciatic, post tibial, internal plantar, crural, internal saphenous, superficial peroneus, median, ulnar, radial, cutaneous median, and radial interosseus nerves, and in every case nearly all these excised organs showed marked degeneration. The changes were in the axis-cylinder and perineurium, as well as in the sheath of Schwann, and the author says they should be regarded as parenchymatous in character. The intensity of the morbid changes was greater in the peripheral endings than in the trunks of the nerve. The vagi were not included in the examination. The spinal cord was inspected in twelve cases and found normal. In all these cases there were no manifestations of nervous symptoms during life, with the exception of some undefined neuralgias and muscle pains, general hyperæsthesia, which usually develop in the high fever and emaciation of phthisical patients.

The fact that not only alcohol, syphilis, and diphtheria, but measles, scarlatina, smallpox, copper, zinc, mercury, etc., are capable of playing a causative *rôle*, both in peripheral nerve disease and in phthisis, opens up the very interesting field of inquiry, which time and space forbid me to enter at present, as to how far these toxic agents are instrumental in maintaining the current death-rate of phthisis. When we consider the all-pervading evil effects of these agents, either in their acquired or inherited form, the conclusion becomes irresistible that they exercise a most powerful influence in this direction.

There is no more reason to suspect, however, that because pulmonary consumption is the morbid product of manifold causes, each cause brings about a specific form of the disease. That the pathological changes may vary in character and in appearance is

1885 and 1886, p. 294; *Rosenbach:* Ibid., vol. iii. p. 40; *Basevi:* Jahrb. f. Kinderheilkunde, 1878, p. 414; *Hanot:* Archiv Gén. de Méd., 1876, tom. 28, pp. 294, 297; *Grocco:* Riv. Clin. 25, p. 12, 1886; *Schmidt:* Jahrb., Bd. 214, S. 29; *Pitres et Vaillard:* Rev. de Méd., 1886, p. 193; *Senator:* Zeitschr. f. klin. Med., vol. xv. S. 61; *Guiter:* Virchow u. Hirsch, Bd. xxii. Part i. p. 203; *Vierordt:* Neurol. Centralbl. vol. v. p. 421; *Buss:* Centralbt. f. d. med. Wis., 1888, p. 195; *Eisenlohr:* Centralbl. f. d. Nervenh., vol. ii. p. 100; vol. x. p. 12.

true enough, but this is probably due more to a difference in the rate at which the disease travels than to a difference in the mode of its causation. If this were true, it would at least lend some color to the view that the nerve degeneration which accompanies what is now known as bacillary phthisis, is due to the destructive action of the bacillus tuberculosis. I have, however, not been able to find the record of a single case in which the tubercle bacillus had been associated with the degenerated nerves in phthisis.

In this connection it is certainly permissible to quote the very appropriate opinion of Dr. Gull, expressed by him in 1859, while discussing two of his cases, to which I refer in this paper. He said (*Trans. Lond. Path. Soc.*, 3d series, vol. 5, 1859, p. 312):

> This case affords an excellent illustration of the effects which are referable to paralysis of the pulmonary plexus on one side, accumulation of muco-purulent secretion in the paralyzed bronchi, subsequent dilatation of the tubes at their peripheral distribution, concomitant exudation into the air cells, hepatization, and at length disintegration of tissue on the other. . . . It is one of the evils of a too exclusively humoral pathology (*bacillary pathology we might say at the present day*)[1] that leads us to overlook the minute anatomical relations of disease, which are in themselves often a key to the sequence of morbid changes. These cases illustrate this proposition, for the possible local effects on the lung of injury to the pneumogastric and pulmonary plexus being recognized, whenever cause for that injury exists we may anticipate its results, and are not wholly dependent upon physical examination as we are if we limit our pathological view to the mere changes in the lung without considering how they are produced.

In his comments on one of his cases, to which I also refer, the eminent Dr. Wilks expresses himself in a similar strain. He says (*Trans. Lond. Path. Soc.*, vol. x. p. 1):

> It has been said that the patient died of phthisis, and the tumors were found accidentally, but in all probability the affection of the nerves—that is, of the pneumogastric, was the cause of the pulmonary disease, and therefore, so far from neuroma being a harmless affection, it was the cause of the girl's death. This idea was suggested by the observation of several other cases of lung disease occurring in connection with disease of these nerves, particularly as witnessed in aneurism of the aorta and cancer of the œsophagus. In these diseases death is often brought about by pulmonary affection, and the pneumogastric nerves are found implicated in the disease or pressed on by the tumor.

This brings up the collateral question whether pulmonary consumption invariably follows vagus disintegration. As a rule this obtains if, as has already been stated, the irritation is sufficiently prolonged. When this is not the case the evidence seems to show that only functional disturbance of the lungs and heart occurs, although I have found records of cases where, in the human subject, it is stated that one vagus was divided without detriment to life. By way of a slight digression I may say that on reviewing the literature from which I culled my cases, it is impossible not to believe that many of our functional and organic heart diseases depend on a lesion of the pneumogastric nerves. So, on the other hand, it must not be expected that a lesion of the vagus or of the nervous system is the primary source of every case of pulmonary consumption. There can be no doubt that phthisis is an auto-infectious disease, as has already been intimated, and that if a process of caseation is once established in the body there is always danger of secondary tubercular infection. Such examples of pulmonary consumption arise in consequence of caseating centres having been established in or around the pelvic organs through the instrumentality of pelvic cellulitis or salpingitis, as well as from caseating lymphatic glands anywhere in the body. I suspect that these causes play a more important rôle in the maintenance of phthisis than is generally suspected, especially in the female sex.

In summing up the evidence which has been adduced in this paper, I think it may be said to demonstrate that nature herself is constantly carrying on the experiment of phthisis-production on an extensive scale in the human family, and this to a degree unattainable in the lower animals through artificial means, and which is not done by an infusion of tubercle bacilli, but by a slow process of nerve degeneration, especially implicating the pneumogastric nerves; and that therefore this disease can no longer be regarded as confining its ravages to the lungs.

TREATMENT.—It is not my purpose at present to enter into any detailed discussion of the special treatment of phthisis, but merely to point out the general therapeutic principles which are indicated by this new line of thought in regard to the origin of the disease. And at the very outset it may be stated that if the value of any one therapeutic measure is more firmly established than that of another, it is that rest is the *sine quâ non* in the cure of nervous diseases. This has been abundantly proven by the scientific and practical researches of Dr. S. Weir Mitchell. Indeed, he demonstrated its efficiency in the treatment of phthisis more than ten years ago, and of which I was ignorant when I first wrote on this subject. He says on page 93 (*Fat and Blood*):

> "I have ventured, without much hope, to treat three cases of phthisis in the same manner (*i. e.*, with rest, massage, electricity, and feeding). There are cases of this nature in which exercise wearies. One of the cases treated got well and remained well. There was every evidence of pulmonary trouble. No. 2 improved enormously in all respects, and relapsed hopelessly, owing to large and repeated bleeding from piles and rectal fissure. No. 3, a male, æt. twenty-four, was treated by rest and massage, without electricity, and improved so as to resume his work."

As for myself, I can say that since I realize its importance I have had a good deal of practical ex-

[1] Italics mine.

perience with this method of treating consumptives, and can testify to its superiority. It is my custom to insist on such patients either to sit quiet or to remain in the recumbent posture during at least seven-eighths of the twenty-four hours. Those who readily tire in these positions for this length of time, must go to bed and remain there constantly for a month or six weeks, or longer if it is considered necessary, allowing only such exercise as is necessary to carry out other lines of treatment.

In order to supplement the active physical exercise of which the patient is deprived by this method of treatment, general massage and electricity must be employed once or twice a day, both of which will be found most useful adjuvants in making the rest-cure of consumption a success. In addition to the general application of electricity and massage, it is also very important to apply these measures locally over the course of the pneumogastric nerve. The galvanic current is preferably employed here, the negative pole being placed under the ear, and the positive pole on the clavicle near its union with the sternum, as well as over the epigastrium.

Flaxseed meal poultices, or the external application of moist heat to the chest, I have employed for a number of years in the treatment of this disease, and with the most gratifying results. These applications are made only during the daytime, and changed every three hours, or oftener, if they become cooler than the body—care being taken that they cover the apices of the chest well.

Another valuable acquisition to the therapeutics of consumption is the inhalation of compressed and the exhalation into rarefied air, or *vice versa*. Any one who has given this method a faithful trial has found abundant evidence of its usefulness. It gives complete ventilation to, and increases the capacity of, the chest; it relieves the dyspnœa, and acts as a powerful tonic to the whole body. In order to reinforce the good effects derived from this method of treatment, the patient must be taught to practise forced respiration—*i. e.*, to take eight or ten forced voluntary breaths in succession every hour or half hour.

In connection with all this, we must not lose sight of the marked benefit which may be derived from internal treatment. Pulmonary consumption is preëminently a wasting disease, and any food or medicine which supplies this constant waste, which facilitates digestion and assimilation, which checks the fever and renders support to the nervous system, is indispensable, and for this reason nutritious foods, cod-liver oil, hypophosphites, antifebrin, antipyrin, strychnine, quinine, atropine, etc., are of such great value, if used with discretion.

Furthermore, it is also obvious that in all cases of dyspnœa where there is no good reason for suspecting that the primary cause for it exists in the respiratory passages, the lungs, or the heart, it is an all-important matter to make a thorough examination of the vagi, even to the extent of cutting down upon them, if necessary, to become thoroughly satisfied that their potency remains inviolate. For these cases undoubtedly show that persistent dyspnœa, aphonia, and hoarseness often depend on paresis of one or both vocal cords (to relieve which tracheotomy often is and has to be performed), in consequence of a pressure upon the vagi or lower laryngeal nerves, by the thyroid or lymphatic gland, or tumor of some kind, which will be relieved by liberating the imprisoned nerves.

SALOL IN THE VOMITING OF INDIGESTION AND OF PREGNANCY.

By R. B. McCALL, M.D.,
of Georgetown, Ohio.

The claims of salol in the treatment of some forms of diarrhœa, particularly cases in which the products of fermentative action are noticeably abundant, are fairly established. In a somewhat extended and varied experience it has achieved more than an ordinary measure of success.

During the recent summer months there was afforded me an opportunity to test its reputed efficacy in dysentery.

Case I. was that of a child seven years of age, and very delicate. The evacuations from the bowels were frequent and large, and decidedly sanguinolent, consisting of about equal quantities of blood and mucus, only partially blended; tenesmus variable in intensity, occasionally exquisite; elevated temperature, accelerated pulse, hurried respiration, coated tongue, unpleasant breath and tympanitic abdomen. The usual treatment failed to afford any relief. Salol was given at first in doses of one and a half grains, gradually increased to two grains, repeated for the first twenty-four hours at intervals of three hours and afterward less frequently. At the end of the first twelve hours evacuations were observed to occur less often, the efforts at stool were less painful, the discharged matters exhibited a diminished proportion of blood. In two days' time the dejecta assumed a nearly normal alvine character — traces of blood and mucus reappeared at intervals for a short time, but convalescence was soon established.

In this instance the elevated temperature, accelerated pulse rate, hurried respiration, tumid belly, and large amount of blood and mucus, much of the former unmingled with the latter, indicated acute catarrhal colitis, set up by fermentative and putrefactive changes. The history and appearance and general condition of the child disclose a state of imperfect nutrition, the result of faulty digestion. Any agent that would modify or arrest fermentation and putrefaction must mitigate or cure the diseased condition resulting therefrom.

Case II.—Maggie W., married, aged thirty-three years, of lymphatic temperament, delicate, no living children, a history of two premature births and of persisting gastric irritability in girlhood. More than three years have elapsed since stomach began to reject all solid food and much of a liquid form, only milk being partially retained, broths of every description sharing the same treatment.

Three years ago I was requested to prescribe, at which time patient's condition seemed deplorable—inanition seemed imminent. So emaciated was she that there appeared to be only the bony frame wrapped in integument; an anxious, hopeless, profoundly fatigued expression Under treatment she made some improvement, retained more of her exclusive article of food than she had previously, but continued to vomit a number of times every day. Vomited matter consisted of whatever had been ingested and a frothy, extremely acid mucus which seemed to excoriate the pharynx and mouth as it flowed up. Patient disappeared from observation, to reappear recently. By the diligent and heroic use of scale pepsin with hydrochloric acid, amendment set in and continued for three months, milk being better borne and digested, and weight in that time augmented by twenty-five pounds, but vomiting persisted.

The resources of the materia medica were taxed with but little additional advantage. The entire armamentarium of antiseptics and acids, bitter and acid tonics, pepsins and lactopeptones, not forgetting ingluvin, were called into requisition, but without avail. Preparations of carbolic acid and creasote were employed with brief temporary relief. Sodium sulphite and sodium phosphate apparently exercised no influence. To add to the embarrassment of the case, the patient became pregnant, gastric irritability increased, with emaciation and threatened prostration.

Of course, every appeal to procure artificial abortion was resisted, and finally nature kindly interfered and brought about the hoped-for event, whereupon although the gastric trouble lost its aggravated intensity and persistency, it still continued.

While the fœtus remained *in utero*, oxalate of cerium, ingluvin, scale pepsin (Jensen's), belladonna, aconite, aconite and belladonna combined, gelsemium, bromide of potassium, carbolic acid, bromocaffeine, and a number of other drugs of more or less repute, were administered with a little apparent advantage from belladonna, oxalate of cerium, and carbolic acid; belladonna was frequently repeated, and carbolic acid given in as large doses as was deemed advisable or safe.

Only the one article of food was tolerated. Oxalate of cerium (which I had very generally found serviceable) exhibited in small or large doses, at long or short intervals, exercised absolutely no effect whatever. Reflecting that the condition of the stomach must be essentially that of the bowels in catarrhal diarrhœa and dysentery, and reasoning that what had been effectual in the one must *à priori* be of some service in the other, salol was prescribed in doses of one and a half grains, repeated at intervals of three hours. For three days no other effects were observed than diminished frequency and difficulty of the effort. Restlessness and sleeplessness vanished, better tolerance for milk was acquired. In the following week the dose was increased to three grains, exhibited thrice daily; result, cessation of vomiting, tranquillity of nervous system, and composure of mind; however, an attempt to take solid food would frequently result in its rejection. Milk is now taken without unpleasant consequences, and some portions of solid nutrient material are retained and undergo perfect digestion; a feat that has not been accomplished for more than three years.

From the foregoing it may fairly be concluded that salol may check fermentative action. I have also given it in two cases of pregnancy with like satisfactory results.

Case III.—Mrs. M., in the eighth month, had been vomiting occasionally through the day, but more particularly and frequently after going to bed at nights, for two months. Whenever the body assumed the recumbent posture the acid contents of the stomach would well up into the throat and the regurgitation-like vomiting would last sometimes for an hour before final subsidence. No other spells during night; no morning nausea or gastric irritability manifested. Salol in two-grain doses was directed to be taken three times a day. In a short time there was marked improvement, the annoyance during the day ceased almost at once. In the course of a week the evening disturbance ceased to recur. The case is still under observation. I am told that a single three-grain powder answers for the entire day.

Case IV.—The other case of this class was in the seventh month of pregnancy, and was not so much annoyed by acid vomiting as by sourness and heartburn, with swelling and hardness of epigastrium. In this, as in the previous instance, the desired result followed on the administration of the medicine.

To sum up, wherever there is indigestion characterized by acid and gaseous eructations or putrefactive changes, or gastric or intestinal catarrh from fermentation, salol is of value. In the indigestion of childhood, from over-feeding or indulgence in indigestible food, where there is a heavily loaded tongue and fetid breath, the drug may be used with good effect.

MEDICAL PROGRESS.

Prophylaxis of Tuberculosis in Prussia.—In the *Berliner klinische Wochenschrift* of May 6, 1889, there appears a notification signed by the President of Police of Berlin, announcing prophylactic regulations against the spread of phthisis—based on Cornet's conclusions—which are at once to be enforced. The notification reads as follows:

By means of Dr. George Cornet's researches regarding the spread of tuberculosis—made under the guidance of Dr. Robert Koch—it has now been proven, beyond doubt, that only the *dried sputum* of consumptives, or those suspected of having the disease, may be injurious to man. The sputum being dried, becomes powdered,

and may then become mixed with the air, thus possibly causing infection of the human body. In order to prevent the spread of tubercle bacilli, which undoubtedly are the cause of tuberculosis, consumptives should be required not to expectorate into a handkerchief, on the floors, or against walls, but to use exclusively a spittoon or spitcup, the latter being especially recommended, as it prevents any soiling of the floor.

Disinfection of the sputum is considered unnecessary by Dr. Cornet, as sublimate does not sterilize it, and carbolic acid is only valuable when used with great precaution. The spitting-cups should be washed in boiling water and their contents thrown into drains. Spittoons containing sand or sawdust should not be used, as they only facilitate the drying and pulverization of the sputa. A small amount of water should always be kept in the spitcup.

On the ground of public health, it is directed by the President of the Police Board that the following regulations shall in future always be enforced in private institutions, insane asylums (as among the insane tuberculosis is frequently observed), and by practitioners to whose care consumptives are committed:

1. Unquestionable consumptives are to be isolated, as far as possible, from patients suffering from other diseases.

2. All patients suffering from this disease, as well as those in whom the disease is suspected, are hereby required to expectorate into spitcups containing a small quantity of water. These vessels are to be washed out with boiling water at least once a day and their contents to be emptied into the drain. Any soiling of the floors, walls, beds, etc., should be immediately cleansed with boiling water, or by other equally effective measures. Soiled clothing and bedding should also be boiled.

3. Beds, mattresses, quilts, etc., as well as all other utensils and furniture used by the patients, must be disinfected in accordance with the police regulations of February 7, 1887, regarding contagious diseases. Articles that cannot be disinfected by boiling must be brought to the City Disinfecting Institute and there undergo thorough disinfection.

4. The rooms occupied by consumptives must, after their death, be disinfected in accordance with the regulations referred to in the preceding paragraph.

Salol as a Dressing.—At the last meeting of the Hunterian Society of London MR. CORNER exhibited a series of cases illustrative of the antiseptic power of salol (salicylate of phenol) as a dressing for wounds, after the part had been rendered aseptic by a 1 in 20 solution of carbolic acid. Salol has a pleasant aromatic odor, can be used freely without fear of irritation or poisoning, is absorbent of moisture, and whilst drying forms a hard but friable covering. It prevents putrefaction, but does not destroy it when established. It has been used in increasing frequency for several years at the Poplar Hospital, and with excellent results in compound fractures and dislocations, also as a dressing in amputations, minor and major, and in compound comminuted fracture of the skull.

The first case shown was a compound comminuted depressed fracture of the frontal bone, in which the bone was elevated, and some spicules removed, the wound being afterward washed with 1 in 20 carbolic acid, the opening filled with salol, and a drainage-tube inserted. The dressing was undisturbed for fourteen days, remained sweet, and the wound healed on the twenty-sixth day. The temperature remained from the first under 100°.

A second case treated in January, 1889, was a compound fracture of the olecranon, head of radius, and humerus, opening the elbow-joint, with considerable damage to the soft parts, the elbow having been crushed by the passage of a railway engine over it. The olecranon was split and drawn up, causing serious tension of skin, and necessitating removal of both portions. The antiseptic treatment and dressing were the same as in the previous case, but required changing after four hours and again next day, in consequence of oozing through; the parts were then left undisturbed for thirty days. The temperature went up the day after the injury, and remained about 101° F. for three days, 100° F. for two days, then became normal.

Two other cases were shown, one a crushed compound fracture of the finger done up twenty-one days before, and not exposed since, there having been neither pain nor elevation of temperature; the other was a compound fracture of the first phalanx of the finger, dressed at the time of the accident, and undisturbed for a month, when it was found perfectly healed. It was pointed out that this was the common experience in such cases, and that even if gangrene followed, the parts remained sweet.—*The British Med. Journal*, May 4, 1889.

Incontinence of Urine in Children.—DR. DESCROIZILLES, in an article on the subject of incontinence of urine in children, says that although the disorder is frequently of nervous origin, it also often accompanies constitutional weakness, and the strict application of hygienic and dietetic principles will frequently cause complete cure. There are many cases where further treatment becomes necessary. Descroizilles has tried various remedies, and states that he has found the following formulæ to be most efficacious:

I.

℞.—Extract of belladonna . . 6 grains.
Powdered gum arabic }
Powdered marshmallow } . āā q. s.—M.

Make into forty pills. One to fifteen to be taken daily, according to the severity of the case.

II.

℞.—Syrup of belladonna . . . ℥ij.
Syrup of tolu }
Syrup of marshmallow } . āā ℥j.—M.

A half teaspoonful two or eight times a day.

III.

℞.—Atropine . . . . . ⅛ grain.
White sugar . . . . . ℥iij.—M.

Make into forty powders. Two to four to be taken daily.

IV.

℞.—Bromide of potassium . . . ℥j ss.
Linden flower water . . . ℥ij.
Syrup of sugar }
Syrup of bitter orange-peel } āā ℥j.—M.

A half teaspoonful one to four times a day.

V.

℞.—Sulphate of strychnine . . 2 grains.
Syrup of sugar . . . . ℥vj.
Water . . . . . ℥ij.—M.

A half teaspoonful one to twenty times a day.

Bromide of potassium is also useful in four-grain doses, given one to four times a day.—*Rev. Gén. de Clinique*, April 18, 1889.

On Ehrlich's Diagnostic Sign of Enteric Fever. — DR. HOWARD TAYLOR, House Physician to the London Hospital, says that the attention of Dr. Sansom, of London, was drawn to the subject of Ehrlich's test for enteric fever, whilst attending the Congress of American Physicians and Surgeons at Washington last year. On his return to England he requested Dr. Taylor to investigate the test, which is as follows:

Ehrlich states that the urine of patients suffering from typhoid fever gives a reaction—with one of the aniline derivates—different from that of normal urine, or of the urine of patients suffering from other diseases. Ehrlich's tests are as follows: *A*, a saturated solution of sulphanilic acid in dilute (1 in 20) hydrochloric acid; *B*, a five per cent. solution of sodic nitrate in distilled water. (Both of these solutions must be fresh, especially the latter, which cannot be depended on for more than a week at the longest. When mixed, of course, a solution of sulphanilic acid containing free nitrous acid is produced, which is the actual test solution; but on account of the extreme instability of the latter the two solutions must be mixed fresh at each testing.) In using the test, about twenty-five parts of *A* are added to one part of *B*. Mix with this an equal bulk of urine to be examined, and render alkaline with strong ammonia.

With normal urine the change will only be a deepening of color into a sherry or vinegar-brown. In conditions of pyrexia other than typhoid fever the color also deepens, but when the test is applied to the urine of a patient suffering from enteric fever the color rapidly becomes red, the tint varying from ruby red to that of a deep port-wine color. On shaking the test tube a froth is produced which has a delicate pink color which is very characteristic.

From the result of Dr. Taylor's experiments with this test, which are given at length in the *Lancet* of May 4, 1889, he concludes that the absence of the reaction is practically a proof positive that the case is not one of enterica (provided that the disease has lasted for six days or more). Its presence suggests — but does not prove—that the case is one of typhoid; the probability being greater the deeper the tint produced. And as the other diseases in which it occurs least rarely are not those which most closely resemble typhoid fever, but the reverse, the significance of these exceptions is very greatly diminished.

Renal Surgery.—The progress of abdominal surgery has specially been marked of late by the increasing number of records of operations on the kidney. Since MR. THOMAS SMITH, twenty years ago, advocated the removal of a renal calculus by operation, and Prof. Simon proved, after making a series of experiments on dogs, that the removal of one kidney did not necessarily produce acute or chronic disease of its fellow, a whole series of operations on the kidney have come into vogue. These are nephrorrhaphy, or the sewing up of a floating kidney by its capsule to the parietes; nephrotomy, or incision into the kidney; nephro-lithotomy, or removal of a renal calculus by nephrotomy; and, lastly, nephrectomy, or removal of the kidney entire. Notwithstanding the truth of Simon's theories, and the encouraging results claimed by several surgeons, nephrectomy must still be considered a very serious undertaking.

There is a great difference of opinion amongst the few really experienced operators as to the right manner of performing nephrectomy. Some, like Mr. Lucas, advocate the lumbar, some, like Mr. Thornton, the abdominal incision. An instructive discussion between these authorities took place on the reading of Mr. Knowsley Thornton's paper on the subject, at the meeting of the Royal Medical and Chirurgical Society on April 9th. The choice of incision, however, is apparently of no essential import, depending rather on the previous experience of the surgeon in abdominal or lumbar sections, as they may conveniently be termed, for tumors, colotomy, etc. Far more important is the question of ascertaining the state of the opposite kidney. Mr. Lucas considered it necessary to estimate for some time the amount of urea excreted daily. If that were found to be less than half the normal quantity, then nephrectomy, he maintained, would be a very serious operation. To this reasonable observation, Mr. Thornton opposed an equally reasonable theory, which superficial thinkers are apt to overlook. If a large suppurating kidney, for example, be treated medically, not surgically, the labor thrown upon its fellow would be possibly greater than that entailed by the operation. Mr. Thornton also quoted one of his cases where both kidneys were diseased, yet when one containing twenty pints of pus was removed, the operation was borne very well.

To form anything like a correct estimate of the excreting power of the healthy organ in cases where the diseased kidney is not absolutely obstructed, is after all very difficult in actual practice. Dr. Tuchmann's ureter forceps, for temporarily blocking the orifice of one ureter for a time, may prove of service, but many find them difficult to apply. Catheterization of the ureter, practised by Newman, of Glasgow, and others, requires much special training.

Lastly, physicians, physiologists, and chemists have possibly more to discover as to the import of each constituent of the urine. As yet, much in respect to calculating the powers of a healthy kidney when its fellow is diseased, is theoretical or empirical. Lastly, renal surgery must for a long time remain in the hands of men well experienced in less severe or better understood operations performed in the same neighborhood.—*The British Med. Journal*, May 4, 1889.

Cancer of the Cervix Uteri.—Total extirpation is a difficult and serious operation. Supravaginal amputation of the cervix is somewhat less difficult, at least to operators not accustomed to surgical manipulations in the neighborhood of the female organs. The after-results of either operation when performed for cancer deserve close observation and accurate record. Should it be proved that cancer of the cervix naturally advances upward or recurs, after amputation of the affected part, in the uterus, the necessity for total extirpation would become evident. An

English authority, Dr. John Williams, maintains that the disease does not tend to spread upward from the cervix, but rather laterally toward the broad ligaments and vault of the vagina. Recurrence after amputation takes place, as a rule, in the neighboring connective tissue, and but rarely in the stump. Hence that authority's preference for supravaginal amputation of the cervix. The Germans are mostly opposed to this practice. Dr. Abel, after examing seven uteri extirpated by Prof. Landau for cancer of the cervix, found malignant degeneration of the endometrium in all. Dr. Fränkel examined six cancerous uteri, and found that, whilst the cervix was cancerous, the uterus was affected with glandular and interstitial endometritis. In other words, the endometrium was not cancerous. On the ground of the general pathological changes which he detected, he nevertheless advocated total extirpation of the uterus. His argument, in this respect, appears as weak as Dr. Abel's is strong. If the endometrium is merely inflamed, removal of the irritating cancerous deposits in the cervix ought to be, so far, sufficient. Dr. Saurenhaus, working in Prof. Olshausen's wards, also found that the changes in the endometrium, in cervical cancer, were non-malignant. Dr. Theim, of Kottbus, after practical observation, came to the same inconsistent conclusion as Dr. Fritsh. He discovered changes in the endometrium, which he held to be inflammatory, not malignant, yet insisted that total extirpation was demanded in cancer of the cervix whenever that severe proceeding was practically feasible.

Consistency in principles as applied to the results of observation, therefore, rests with Dr. Abel and Dr. John Williams; unfortunately, their conclusions are diametrically opposite. We need more observations on the condition of the endometrium in cancer of the cervix, and more records of after-histories where either of the abovementioned operations have been undertaken with success. —*The British Med. Journ.*, May 4, 1889.

Treatment of Erysipelas with Alcohol.—BEHREND states that he has found absolute alcohol to be an active poison to the micrococcus of erysipelas. He cites numerous cases where thorough washing of the affected parts, three or four times a day, with absolute alcohol, produced complete recovery in less than a week. The micrococci in every case disappeared almost immediately.—*Centralbl. für klin. Med.*, April 20, 1889.

Uralium, a New Hypnotic.—DR. G. POPPÉ, of Bologna, recently presented the Medico-chirurgical Society of that city with a monograph on uralium, a new hypnotic, being a composition of chloral and urethan. Poppé claims that it is both safe and efficient, and strongly recommends it in cases of insomnia of hysterical origin or cardiac trouble.—*Gaz. degli Ospitali*, Feb. 4, 1889.

Intra-pleural Injection of Naphthol in Purulent Pleuritis.—PROF. BOUCHARD has recently used intra-pleural injections of naphthol with marked success in two cases of severe purulent pleuritis, doing away with the necessity for operation for the empyema. He injected twice daily 30 to 60 ♏ of the following solution:

Naphthol	ʒjss.
Alcohol	f ʒj.
Distilled water . .	q. s. ad f ʒiijss.—M.

The quantity of naphthol injected was, therefore, two to four grains daily. As soon as the solution is injected the naphthol is freed, but is again partly dissolved in the exudation, and sterilizes the contents of the pleura. No unpleasant symptoms were observed to follow its use. —*Wiener med. Presse*, April 28, 1889.

Potatoes as a Substitute for Laparotomy.—The *Canadian Practitioner* of May 1, 1889, quotes the following from the *International Journal of Surgery*. At a meeting of the Imperial Society of Physicians in Vienna, DR. SALZER reported a communication from Dr. Cameron, of Glasgow, upon the "potato cure" first recommended by the Scotch observer. Dr. Cameron has used this plan of treatment in several cases of ingestion of large foreign bodies with gratifying success. Salzer has also had an opportunity to try the potato cure in the case of a boy who had swallowed a brass weight of twenty grammes. Potatoes were fed to the child cooked in a variety of manners, so as to encourage his appetite. He took them willingly. After five days the brass weight was compelled to retreat, overwhelmed by the constant accessions of reinforcements from above, and passed out, leaving the potatoes in possession of the field. In the same manner he treated the ingestion of a set of artificial teeth, while in another case a scarf-pin proved no match for its farinaceous antagonist. Dr. Salzer believes that this form of treatment will subserve a useful purpose in many cases in which, up to now, gastrotomy appeared to be the only form of relief available. He also advised the members to place no trust in sauer-kraut, which has been recommended for the same purpose. Dr. Hochenegg related the case of a boy who had swallowed a nail six ctm. long in 1884, and had been treated by gastrotomy. He had swallowed a similar nail two years later, when the potato cure had proved successful. Dr. Billroth spoke of the difficulty which exists in the removal of foreign bodies by laparotomy, and was strongly in favor of the potato cure.

Uncontrollable Vomiting of Pregnancy.—Few medical subjects can be of higher interest to the practitioner than this fortunately rare condition. DR. STOCKER, of Lucerne, has recently contributed an instructive case to the *Centralblatt für Gynäkologie*, No. 16, 1889. The patient married when 21 years of age, but her husband died a year afterward, and she had not then become pregnant. When 30 years old she married again; nine months later she was pregnant. At the fifth week of gestation, morning sickness set in. After the seventh week the vomiting became constant, and continued, when the patient was nourished by enemata alone. Emaciation progressed with rapidity. At the fourteenth week abortion was induced by means of laminaria tents, but great difficulty was experienced in getting the tents through the os internum. Recovery was rapid. Next year the patient again became pregnant. The vomiting began at the fourth week. At the twelfth week, induction of abortion was attempted, but the same difficulty was experienced in passing tents beyond the internal os. The ovum was ultimately brought away by intra-uterine injections of hot water. The vomiting then ceased. About a year and a half later the third pregnancy began. In the fifth week the uncontrollable vomiting set in. Copeman's treatment (dilatation of the whole cervical canal), caus-

tics applied to the os, and the internal administration of bromine and cocaine all proved unavailing. Induction of abortion was, therefore, attempted by intra-uterine injection. There was great resistance to the introduction of the catheter at the os internum. No pains set in, so next day the injection was repeated. The waters escaped, but no pains occurred. Then a laminaria tent was introduced. Directly the internal os was dilated the sickness ceased. The ovum and membranes were extracted manually. No albuminuria nor other evidence of visceral disease existed in this case. An exhaustive clinical and scientific monograph on the "Uncontrollable Vomiting of Pregnancy," by Dr. Graily Hewitt, is to be found in the twenty-sixth volume of the *Transactions of the Obstetrical Society of London*. The discussion, by eminent obstetricians, is highly instructive.—*The British Med. Journal*, May 4, 1889.

Influence of Massage upon the Secretion of Urine.—Dr. A. Bum (*Centralbl. für Chir.*, April 27, 1889) has been recently investigating the influence of massage upon the secretion of urine, and for this purpose has subjected a large number of dogs to vigorous treatments of massage. These novel experiments have showed him, however, that massage of the lower, or rather hind, extremities, materially increased the secretion of urine. This occurred in every case. Bum explains this action by the influence of massage upon the venous circulation. He confidently states that this method of treatment will undoubtedly become a valuable therapeutic agent.

The Antiseptic Properties of Sulphuric Acid Gas.—Drs. Dubief and J. Bruhl have recently conducted a series of investigations regarding the germicide properties of certain gases, especially of sulphuric acid gas. They have come to the following conclusions:

1. Sulphuric acid gas kills all germs with which it comes in contact in the air.
2. The action of the gas is the same when saturated with steam.
3. Sulphuric acid is a powerful antiseptic.
4. The dry fumes are quicker in action than the aqueous vapors of the gas.—*Gaz. hebd. de Méd. et de Chir.*, April 26, 1889.

Dangers of Chloroform in Laparotomy.—Professor Zweifel, of Berlin, has remarked several times that pneumonia has occurred after laparotomy has been performed under chloroform, either at night or on dark days when gas had to be used. In some cases, which were done in a small, badly ventilated room, where a good many bystanders were present, and two or three Argand gas-burners were in use, a peculiar cloud of partly decomposed chloroform vapor was very noticeable, not only to the eye, but by the effects produced on the respiratory organs of the operator and his assistants. When ether was used instead of chloroform these effects were not observed. Pending the establishment of the electric light, Professor Zweifel commences with a mixture of alcohol, chloroform, and ether alone, the patient being put under the influence of this in another room, ether being subsequently used during the operation.—*Lancet*, May 4, 1889.

The Local Treatment of Diphtheria.—The question of a purely local treatment of diphtheria has been agitating the minds of many practitioners of late. The existence of the bacillus of croup and diphtheria, first discovered by Hoeffler, is now accepted by the great majority of physicians, and the existence of such a germ immediately calls for its speedy extermination at the seat of its growth, both for curative as well as prophylactic reasons. With this method of treatment in view we are confronted by a long list of antiseptics of various merits. To facilitate a proper conception of their relative value, Dr. Kocii has prepared a table, showing the minimum strengths of solutions required to insure disinfection. These are quoted by Dr. Ferdinand Fruhwald in the *Wiener klinisch. Wochenschr.*, April 25, 1889.

	Marked decrease of the growth of the bacillus occurs in a solution of:	Total arrest of the growth of the bacillus occurs in a solution of:
Bichloride of mercury	1 to 1,160,000	1 to 300,000
Oil of mustard	1 to 330,000	1 to 33,000
Allyl alcohol	1 to 167,000	
Arsenite of potassium	1 to 100,000	1 to 10,000
Thymol	1 to 80,000	
Oil of turpentine	1 to 75,000	
Hydrocyanic acid	1 to 40,000	1 to 8000
Oil of peppermint	1 to 33,000	
Oil of cloves	1 to 5000	
Green or soft soap	1 to 5000	1 to 1000
Iodine	1 to 5000	
Hydrochloric acid	1 to 2500	1 to 1700
Boric acid	1 to 1250	1 to 800
Permanganate of potash	1 to 1400	
Salicylic acid	1 to 3300	1 to 1500
Benzoic acid	1 to 2000	
Carbolic acid	1 to 1250	1 to 850
Camphor	1 to 2500	over 1 to 2500
Quinine	1 to 830	1 to 625
Alcohol	1 to 100	1 to 125
Salt	1 to 64	

Many of the above antiseptics are very slow in action, and many are unfitted for such uses as spraying the mouth and throat, and would not, therefore, be of practical value in the local treatment of diphtheria. Our reader will, therefore, be able to gain more from the following table, which was compiled by Dr. Miller, of Berlin.

Antiseptic.	Concentration.	Time necessary for sterilization of mouth and throat.
Salicylic acid	1 to 100	¼ minute.
Benzoic acid	1 to 100	¼ "
Salicylic acid	1 to 200	½ "
Bichloride of mercury	1 to 2500	½ to ¾ "
Benzoic acid	1 to 200	1 to 2 minutes.
Thymol	1 to 1500	2 to 4 "
Bichloride of mercury	1 to 5000	2 to 5 "
Carbolic acid	1 to 100	10 to 15 "
Oil of peppermint		10 to 15 "
Oil of wintergreen		over 15 "
Lime water	no action.	

The majority of authorities seem to agree that the use of the spray, by means of an anatomizer, is preferable to the practice of "painting" the throat, as the latter method may frequently result in serious injury to the mucous membrane.

Precocious Menstruation: Amenorrhœa with Convulsions.—A case of remarkably precocious menstruation is reported

by DR. DIAMANT, of Vienna.[1] When a twelvemonth old, the child had cut all her milk teeth. When barely two years of age, the first period was observed. It lasted four days, and recurred with regularity till the child was six years old. At that age her breasts, loins, and pelvis were of the adult type: the axilla and pubes were thickly covered with hair. Suddenly the period ceased, and for six months after the child had completed her sixth year epileptiform convulsions came on during sleep, at every date when the catamenia should have appeared. The fits sometimes lasted three-quarters of an hour, and increased in number every month. They were continuing when the case was reported, the child being then 6½ years old.—*The British Med. Journal*, May 4, 1889.

Digestive Tablets.—*L'Abeille Médicale*, of April 27, 1889, gives the two following "antifermentative" formulas as prescribed by DR. DUJARDIN-BEAUMETZ:

I.

℞.—Salicylate of bismuth, Magnesia, Bicarbonate of soda . . . āā ʒijss.

Make into thirty powders or tablets.

II.

℞.—Salicylate of bismuth, Naphthol, Magnesia . . . āā ʒijss.

Make into thirty powders or tablets.

Dose: One tablet at breakfast and one at dinner. They are especially valuable in dilatation of the stomach caused by fermentation.

Menthol in the Treatment of Laryngeal Tuberculosis.—The *Prager med. Wochenschr.*, April 17, 1889, speaks of DR. A. J. OSSENDOWSKI'S treatment of laryngeal tuberculosis with ten to twenty per cent. solution of menthol. After carefully observing its action in a number of cases, the following conclusions were arrived at:

1. Menthol seems to act as a good anodyne in this disease.

2. It is of considerable value in the local treatment of laryngeal tuberculosis.

3. To begin with, a solution not stronger than ten per cent. should be used, which may be advantageously increased. Stronger solutions (forty to fifty per cent.) cause severe irritation.

Laxative Powder.—DR. DUJARDIN-BEAUMETZ recommends the following as a pleasant and reliable laxative:

℞.—Powdered senna pods (treated with alcohol), Sublimate of sulphur	āā ʒjss.
Powdered fennel, Powdered star aniseed	āā grs. 48.
Pulverized cream of tartar	grs. 31.
Powdered liquorice	ʒij.
Powdered sugar	ʒvjss.

Dose: One dessertspoonful of the powder in a half wineglassful of water at night.—*L'Abeille Médicale*, April 27, 1889.

[1] Internat. klin. Rundschau, 1888, No. 40.

Mercurial Vapor in Croup.—DR. ROTHE, of Altenburg, relates (*Memorabilien*, 6 Heft, 1889) two cases of apparently non-membranous croup in which, when the laryngeal stenosis became so great as to oblige him to propose tracheotomy, the inhalation of the vapor of calomel produced such a remarkable change for the better that he was able to dispense altogether with the operation. He rigged up a sort of tent over the child's head and vaporized thirty grains of calomel on a metal plate over a spirit-lamp. This produced a marked improvement in the breathing in a few minutes, and shortly afterward the child fell asleep bathed in perspiration. The inhalation was ordered to be repeated every two or three hours, but with smaller doses of calomel; also, whenever a severe attack of dyspnœa came on, an extra inhalation was given, and never failed to produce the desired effect. Though the inhalations were continued for a couple of days there was no salivation or diarrhœa, but the vapor set up some little irritation about the eyes, which made the little patients rather fractious; otherwise no unpleasant effects were produced.—*Lancet*, April 27, 1889.

Opium as a Hemostatic.—A case of severe bronchial hemorrhage came to the notice of DR. HUCHARD, which, in spite of most active treatment, had continued for some time. He used ergot, injections of ergotine, sulphate of quinine, ipecac, and other remedies without avail. Finally he tried injections of morphine, four or five times daily, in $\frac{1}{12}$ grain doses. The hemorrhages ceased entirely after the first day of treatment. Dr. Huchard has since tried the drug in cases of uterine hemorrhage and too copious menstruation, always with marked success.—*Journal de Méd. de Paris*, April 21, 1889.

Surgery of the Spinal Cord.—DR. LAMPIASI tells of the case of a man, aged twenty-eight, who was thrown from his horse, which fell on him. There was sensory and motor paralysis, with loss of control of the bladder and rectum. There was some prominence of the twelfth dorsal vertebra. An incision was made over the spinous process, and the bone was exposed. There was fracture of the left superior articular process and of the left transverse process of the twelfth vertebra, with luxation backward of the right upper articular process so as to override the lower articular facet of the vertebra above. The two superior processes of the twelfth vertebra were resected, and the dislocation reduced. There was no improvement in the symptoms, and death occurred six days after the operation. At the *post-mortem* examination there was found rupture of the lateral ligaments, detachment of the intervertebral disk of the twelfth vertebra, which remained adherent to the eleventh, and projected three-quarters of an inch into the spinal canal, where it pressed on the front part of the cord.—*The British Med. Journal*, May 4, 1889.

Local Application of Pepsin.—DR. H. B. DOUGLAS has found pepsin a most valuable application for indolent ulcers. It gives a healthy appearance to the sore, and promotes rapid healing. He uses it with lanolin in the following combination:

℞.—Pepsin	48 grains.
Lanolin	ʒjv.—M.

—*Revue de Thér. Méd.-chir.*, May 1, 1889.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE . . . . . $5.00.

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, MAY 25, 1889.

SO-CALLED WEIL'S DISEASE.

IN 1886 Prof. Weil, of Heidelberg, reported four cases which he regarded as examples of a hitherto unrecognized disease. The patients were all young, previously vigorous, healthy males, and the illness attacked them during the months of June and July. The symptoms from which Weil inferred the presence of a new disease were acute fever attended with grave nervous symptoms, such as cephalalgia, vertigo, disturbed sleep, delirium, and somnolence; with swelling of the spleen and liver, icterus, albuminuria, and signs of disordered digestion, such as anorexia, coated tongue, constipation, and diarrhœa. In from five to eight days the icterus, the swelling of the spleen and liver, and the albuminuria gradually disappeared, and the temperature became normal. The disease, however, was not at an end, for, in three of the four cases, after an afebrile interval of from one to seven days, the temperature again rose and another febrile attack of from five to six days' duration set in. The patients then entered upon a stage of protracted convalescence, and were not discharged from the hospital until from four to ten weeks after their admission.

These are the main symptomatic features of four cases ending in recovery, of which the imperfect study has led to the hasty assumption of a new disease. The report of a single case of the commonest disease is incomplete, for scientific purposes, unless details of a necropsy are given. How much more is this statement applicable to obscure cases of disease, and especially to those which are supposed to represent an affection that has escaped the observation of the entire medical world! The study of symptoms is of the utmost importance, but it must not be forgotten that, like the human countenance, they may vary within wide limits, while the pathological ego which they represent remains one and the same. Intercurrent and complicating affections, like conflicting emotions, may so distort the normal expression of a disease that its recognition is only possible to its most intimate acquaintances. From this point of view a change of type in disease would correspond to the permanent change of expression produced by age.

Such thoughts as these, when expressed, are at once recognized as familiar to all, but the tendency of the familiar to become contemptible is as strong as chemical affinity, and finds expression in one of the pithiest of our proverbs.

To return to the question of Weil's disease, so called. Is there such a disease? This question has been ably discussed by Ricklin, in four recent numbers of the *Gazette Médicale de Paris*, and by Fraenkel, in the *Deutsche medicinische Wochenschrift*, 1889, No. 9. In these two able contributions may be found a complete *résumé* of the literature of "Weil's disease."

The following reasons for regarding this affection as an independent one have been advanced. From acute yellow atrophy of the liver it is distinguished by the swelling of that viscus, by the high temperature, by the simultaneous swelling of the spleen, by the involvement of the kidneys, and by the absence of hemorrhage; and from catarrhal jaundice by the higher range of temperature and the implication of the spleen, liver, and kidneys. It resembles relapsing fever in many respects, especially the variety called by Griesinger bilious typhoid. This disease, however, never exists in sporadic form, and hence may be excluded even in the absence of the important negative evidence that would have been furnished by an examination of the blood for the spirillum of Obermeier. The concurrence of jaundice, apyretic intervals, and distinct relapses, suffices to exclude the view that the affection is an abortive typhoid complicated with jaundice. It is admitted, without further parley, that the affection belongs to none of these, nor to any similar, categories. In the absence of further information, we confess ourselves unable to classify the cases reported by Weil.

Happily this is forthcoming, and of the kind imperatively demanded. In the short time that has elapsed since Weil's publication, a number of similar cases have been reported, several of which were fatal and were examined post-mortem.

In 1887, under the title of "Acute Parenchymatosis," AUFRECHT reported two cases of acute fever with jaundice and albuminuria, which, after a rapid course, in which brain symptoms, such as somnolence and convulsions, were prominent, ended in death. In both, necropsies were held. In one the liver was small; in the other, enlarged. In the latter the cellular elements of the liver and kidney were filled with strongly refracting granules, which Aufrecht, without proving his supposition by appropriate staining methods, regarded as micrococci.

NAUWERCK examined, post-mortem, two cases of fatal febrile icterus, in one of which death occurred within forty-eight hours. In this rapidly fatal case the liver was not enlarged. In the intestine were small, superficial ulcerations and enlargement of solitary follicles and Peyer's patches. An intestinal mycosis was supposed to be the fundamental process, inasmuch as the mucous membrane contained small foci of cellular infiltration, in part necrotic, in the immediate neighborhood of which accumulations of bacilli were found. The parenchyma of the liver and kidneys presented a high degree of albuminous, fatty, and necrotic degeneration. In the second case, which lasted seventeen days, the intestine was perfectly sound, while the lesions of the liver and kidneys were identical with those of the first. Nauwerck concludes, from these examinations, that anatomical and etiological unity are both wanting in "Weil's disease."

The third case of this affection in which a necropsy was held was reported quite recently by BRODOWSKI and DUNIN. The patient, a male, thirty-six years of age, besides febrile icterus and swelling of the liver and spleen, presented a symptom that has been wanting in all the other cases reported, viz., swelling of all the superficial lymph-glands. They were tender on pressure and enlarged, some of them to the size of walnuts. On section, these, as well as the enlarged mesenteric and bronchial glands, were soft and of a reddish-gray color. In the liver gray spots and nodules could be seen with the naked eye, which corresponded to round-celled infiltrations of the acini and their neighborhood. The cells were in a well-marked state of cloudy swelling. Analogous appearances were observed in the kidneys, and the interstitial tissue of the lungs was infiltrated with cells. The spleen was five times the normal size. No definite conclusion could be drawn from the bacteriological investigation.

From the reports of these necropsies it is evident: 1. That the post-mortem appearances were, in no single case, identical with those of any other; and, 2. That the only lesion common to all the cases—the cloudy swelling of the liver and spleen, with small-celled infiltration of the connective-tissue of these glands—was in nowise typical. The same appearances are characteristic of a number of infectious diseases, such as scarlatina, diphtheria, typhoid, and especially septic infection.

The question next in natural order is whether any facts support the view that sepsis may give rise to the symptoms described by Weil, and the answer is most decidedly in the affirmative. Since 1876, FIEDLER has observed thirteen cases of febrile icterus, all of which recovered. Supposing the symptoms of Weil's cases to be typical of any morbid process, many of Fiedler's cases presented marked aberrations from this type. For instance, swelling of the spleen and liver and albuminuria were not always present, and in only two cases was there a distinct relapse. The only symptoms invariably present were fever, icterus, and pain in the calves, which latter Fiedler regards as pathognomonic. The most remarkable etiological fact in connection with these cases is that out of the twelve males among them, nine were butchers who were actively at work in the Dresden abattoir until the time of their seizure. Two others attributed their attack to sausages which they had eaten. Most of the cases, like those of Weil, occurred during summer.

The most remarkable case of this sort yet reported was observed by FRAENKEL, and the evidence it brings to the support of the septic theory of "Weil's disease" is of the strongest kind. The patient was a medical student who, while fencing, received a wound of the forehead. In addition, there was a slight excoriation in the right temporal region. The wound was dressed antiseptically and covered with a bandage, which, however, did not protect the excoriation. On his way home the patient wore a hat which had been kept in the dissecting-room. The wound was received on the third of August. On the fifth there was a chill followed by high fever, and on the seventh by an erysipelatous redness around the excoriated spot. On the tenth there was pronounced icterus, and, without going into further details, all

the symptoms of Weil's cases, including the apyretic interval, the relapse, and the protracted convalescence were well marked. The spirillum of Obermeier was sought for in vain.

Among the widely varying symptoms and post-mortem appearances of the numerous cases of "Weil's disease" now on record there is nothing distinctive of a hitherto unrecognized disease. On the other hand, there is strong evidence that some of them were cases of septic poisoning. In Fraenkel's case, which corresponded in all respects with those described by Weil, the point of septic infection was a wound of the head; and in Fiedler's cases, at least in the nine butchers, the infection may have entered the system in a similar manner, through cuts and abrasions too slight to attract attention, or through the ingestion of decaying meat.

The designation of such manifestations of sepsis as "Weil's disease," while it has served the valuable purpose of directing more special attention to them, is a misnomer. Much more appropriate is the term septic or infectious icterus, proposed by Fraenkel.

HYSTERIONICA BAYLAHUEN.

This plant, which is a native of Chili, has been brought forward in the February 28th number of the *Bulletin Général de Thérapeutique* by Dr. Baillé, and also before him by Cervello, of Valparaiso, as a remedy of very considerable value in gastro-intestinal troubles, such as dysentery, colitis, and flatulence from intestinal dyspepsia. The drug is to be used in the form of an infusion made by adding one part of the plant to five ounces of water, or in the form of the tincture prepared by the maceration of three and a quarter ounces of hysterionica in sixteen ounces of ninety per cent. alcohol during ten days. After this the liquid is to be decanted, the tincture being of an amber color and having an odor of the plant. The dose is fifteen to thirty-five drops.

The conclusions reached by Baillé as to the drug are as follows, after having studied it in each portion of the body *seriatim*. It is an excellent remedy for diarrhœa and acts very well in dysentery of the acute and chronic type and bids fair to replace the balsams in the treatment of maladies of the respiratory passages.

The rather curious statement is made that the tincture will not produce constipation.

In genito-urinary troubles hysterionica is of great value, modifying the secretion of the urine and diminishing the bad odors. It can also be used in collodion as a dressing for ulcers, and seems under these circumstances to act very much like the tincture of benzoin.

Tuberculosis is the most generally diffused of human diseases, and therefore all studies relating to its causation and prevention are of the highest interest. The discovery, in 1882, by Koch, of the bacillus of tubercle, and the causative relation it bears to tuberculosis, have received wide-spread acceptance, and the very recent researches of his pupil, Cornet, upon the dissemination of tubercle bacilli outside of the body have given us information of great use in the prophylaxis of the disease. The Prussian Government, which is never slow to render available the latest researches of science for the benefit of its people, has embodied the practical outcome of the investigations of Cornet in a series of regulations for the prevention of the spread of phthisis, which have been promulgated in an official order which will be found on page 571 of this number of The News.

Now that the suspension treatment of disease of the spinal cord has come into general use, the danger of its self-application, when alone, should be carefully impressed upon the patient, and the moral can be well pointed by the death of Dr. Vincent, of the Clifton Springs Sanitarium, who was found a few days ago hanging lifeless from the tripod. The indications pointed to the fact that he was experimenting with the tripod with the view of noting the effects of suspension in his own case, and that by some accident he lost control of the rope, and at the same time the chin strap slipped over his mouth and nostrils and suffocated him. According to *The World*, Dr. Sayre had a similar experience several years ago, in the case of a young lady who is supposed to have fainted while in the tripod, and to have been suffocated in a like way.

We are surprised to read in our usually accurate contemporary, *The Boston Medical and Surgical Journal*, that Dr. Hunter McGuire, of Richmond, Va., had been elected to fill the vacancy in the Chair of Surgery at the Jefferson Medical College, of Philadelphia. The statement is the more curious as Dr. McGuire was not in any way a candidate for the position.

According to the *Boston Medical and Surgical Journal*, the Iowa State Board of Health has decided

that Iowa medical colleges, after 1891, shall be required to give a four years' course to secure their graduates admission to practise in the State.

THE American Laryngological Association will hold its eleventh annual Congress at the Arlington Hotel, Washington, on Thursday, Friday, and Saturday of next week, under the presidency of Dr. E. Carroll Morgan, of Washington. We present the programme in full in another column. After adjournment on Saturday, there will be an excursion to Mount Vernon.

THE Pennsylvania State Medical Society holds its thirty-seventh annual session at Pittsburg, on June 4th, 5th, and 6th, under the presidency of Dr. J. B. Murdock, of Pittsburg. The Address in Medicine will be delivered by Dr. J. C. Wilson, of Philadelphia; in Hygiene, by Dr. T. J. Mays, of Philadelphia; in Laryngology, by Dr. W. H. Daly, of Pittsburg; in Surgery, by Dr. J. B. Roberts, of Philadelphia; in Obstetrics, by Dr. Frances N. Baker, of Delaware County; and in Mental Disorders, by Dr. Alice Bennett, of Norristown.

THE Ontario Medical Association will meet at Toronto, on June 5th and 6th.

THE latest mails from Colombo, Ceylon, says the London *Medical Press*, May 1, 1889, bring accounts of a serious outbreak of cholera in the island. Upward of sixty fatal cases had occurred in one township, and the people were in a state of panic.

SOCIETY PROCEEDINGS.

THE AMERICAN SURGICAL ASSOCIATION.

Annual Meeting, held in the Army Medical Museum, Washington, May 14, 15, and 16, 1889.

TUESDAY, MAY 14TH—MORNING SESSION.

The Association was called to order at 11 A.M., by THE PRESIDENT, DR. DAVID W. CHEEVER, of Boston, who then delivered his

ANNUAL ADDRESS.

He believed that we are warranted in saying that the future of surgery is without limit. He deduced this conclusion first from considering what the mind of man has already done; second, from the future possibilities of fields hitherto unknown and unexplored, but now opening up to science, there can be but two limitations —either in the mind of man, or in the subject.

In estimating, then, the limitations of surgery, we find none, except they be set by ourselves. How should they be set? By conservative judgment opposed to rashness. In the list of modern and useful operations as distinguished from those barely justifiable, are the following:

1. To remove growths or foreign bodies from the cavities of the body: Opening the brain, opening the spinal cord; displacement of the upper jaw or of the nose for naso-pharyngeal polypi; cutting into the pharynx from outside the neck, to remove tumors of the tonsil; œsophagotomy for foreign bodies; thyrotomy for growths; gastrotomy for foreign bodies; opening the gall-bladder for the removal of stones; opening the pelvis of the kidney for calculi; supra-pubic cystotomy for calculi and tumors of the bladder; ovariotomy; removal of the diseased uterus or its appendages; laparotomy for gunshot wounds; and for extra-uterine fœtation; excision of the lower part of the rectum for growths.

2. To reach and evacuate inflammatory products: Opening the chest and resecting the ribs for empyema; opening the abdomen for appendicitis, or for chronic peritonitis; opening and drainage of pelvic abscesses; of abscess of the vertebræ; opening of deep abscess of the neck; evacuation and draining abscesses of joints; peri-nephritic abscess and removal of one kidney.

3. To relieve obstruction: Intubation and tracheotomy; gastrostomy, and enterostomy; colotomy; perineal section; herniotomy.

4. To restore continuity: Resection and suture of bowel; resection and union of bone; resection and reunion of nerves; nerve-grafting; reunion of tendons and of muscles.

5. Unclassified procedures: Plastic and osteo-plastic surgery; modifications of orthopedics, including bone sections and excisions; litholapaxy; reduction of dislocation of the hip and of the shoulder by applied anatomy; endoscopy; rhinoscopy and removal of turbinated outgrowths; pathology and removal of adenoids; aseptic wiring of fractures; local anæsthesia in setting fractures; closing of skull wounds by the insertion of buttons of bone.

6. Operations as yet *sub judice* or on trial: Resection of pylorus; resection of cancerous intestine or omentum; removal of the spleen; of large bronchoceles; of the larynx; the pancreas; the prostate gland; the normal ovary; fixation of the kidney, or of the uterus; puncture of the pericardium; opening gangrenous abscesses in the lung; tapping the ventricles of the brain.

Rash statements are to be discounted; rash operations are to be discouraged. The wisdom of our earliest Greek master in analyzing the imperfections of our art holds true to-day: "Ars longa, vita brevis est; occasis fugax, experimentia fallax; judicium difficile." Yet with Bacon came the new light of experiment. In his immortal words: "Recte veritas temporis filia dicitur, non auctoritas." Lean not on authority; the test of truth is time.

MISCELLANEOUS BUSINESS.

The death of Dr. S. W. Gross, of Philadelphia, was reported, and Drs. D. W. Yandell, J. Ewing Mears, and P. S. Conner were appointed a committee to prepare appropriate resolutions.

The Committee on Nominations was announced as consisting of Drs. D. Hayes Agnew, William T. Briggs, Hunter McGuire, John S. Billings, and J. R. Weist.

On motion of Dr. L. McLane Tiffany, the Secretary was requested to wire to Dr. T. G. Richardson, of New Orleans, the senior vice-president, who was prevented by illness from attending the meeting, the regrets of the Association at his absence.

DR. D. W. CHEEVER, of Boston, then reported a case of

SARCOMA OF THE TONSIL; EXCISION.

The patient, a male, æt. fifty-seven, single, for one year had to breathe through the mouth on account of enlargement of the left tonsil. No pain was experienced until November 1, 1888, when he "caught cold" and the tonsil swelled considerably, and became sore and tender, and discharged spontaneously a few days later. At the same time he noticed some enlarged glands in the left neck. The glands gradually increased in size. The tonsil caused no more pain, but there was an increasing sense of fulness behind it, increasing dysphagia, and difficulty in articulation. There was loss of appetite and weight. When he came under observation January 14, 1889, the left tonsil was found to project nearly to the uvula and was as as large as a pullet's egg. There were two glands in the left neck each as large as a horse-chestnut.

The operation was performed January 17, 1889, ether being given, and the patient being in the sitting posture. A gland in front and one behind the sterno-cleido-mastoid muscle were removed. The first incision was semi-lunar, concave upward, marking the boundaries of the digastric triangle. A second incision over the lower jaw at right angles to the middle of the first incision was then made. The mylo-hyoid muscle was now divided and the other tissues pushed to one side. The lower jaw was then sawed in two in front of the masseter muscle. The tumor was pressed out by finger in the mouth, and was found to be covered with a delicate capsule. On puncture a soft material exuded. The tumor and capsule were removed without great difficulty. There was no hemorrhage, and the facial artery and external jugular veins were the only vessels ligatured. The wound in the pharynx was not sewed; the jaw was wired, the external wound in the skin was partially approximated and washed with two per cent. boracic acid solution and dressed with boracic gauze. The wound was dressed daily. Healing took place rapidly with no unfavorable symptoms. On the thirtieth day the wire was removed and the jaw found to be firmly united. Microscopical examination showed the growth to be round-cell sarcoma.

April 27, a second operation was performed for a tumor on the same side of the neck. The throat, however, remains healthy. A large glandular mass was removed from the anterior carotid triangle. This also proved to be a round-cell sarcoma.

DR. D. HAYES AGNEW, of Philadelphia, said that there are several points of interest in connection with sarcoma of the tonsil. Including the case of Dr. Cheever, he thought there are only ten or eleven recorded. A second point is the fact of constant recurrence. He believed that there is only one case on record where return has not taken place. In that case the thermo-cautery was employed. Various operations have been employed—enucleation, the écraseur, the galvano-cautery, the thermo-cautery, and the external method first used by Dr. Cheever. The operation, when undertaken, should be done simply with the view of palliation. The operation from without is confessedly a difficult operation, and while in the hands of experts it probably affords the best opportunity for the removal of all diseased structure, for the general operator some other method would no doubt be better. He had been much struck with the exposure gained by simply slitting the cheek in operations on tumors far back in the throat—as far back as the soft palate. This would probably give as good a chance of success as any other plan of procedure.

DR. A. VANDER VEER, of Albany, said that the first well-marked case of sarcoma of the tonsil that had come under his observation was in a man aged seventy-two years. The tumor had been discovered four months before he saw him. There was a full, round tumor of the tonsil, interfering seriously with deglutition and somewhat with breathing. The patient selected enucleation in preference to the operation from the outside. His intention was to remove all that he could with the tonsillotome, cutting from behind forward, then enucleate with a blunt instrument and use the thermo-cautery. After cutting through the capsule the tonsillotome slipped behind the tonsil and it was completely enucleated. He did not apply the thermo-cautery. The patient had no return of the disease for eight months. The growth then reappeared and rapidly increased in size. Two months later the patient was taken with pneumonia and died in a few days.

DR. P. S. CONNER, of Cincinnati, thought that the statements in reference to the infrequency of sarcoma of the tonsil are hardly correct. He knew of several unreported cases, two of which came under his own observation. One was in a woman aged twenty-six years. The disease was so far advanced that he thought no operation justifiable, and she died a few days later. The second case was a man aged forty years. The tumor was as large as the fist. He operated by slitting the cheek and was able to separate the tumor readily from the capsule with the finger. The operation was done in June. In July he was apparently in excellent condition. The disease began to recur in the latter part of August and grew rapidly, and in October he was found dead in bed, supposed to have committed suicide.

DR. M. H. RICHARDSON, of Boston, some time ago removed a sarcoma of the tonsil by external incision. The enucleation was accomplished with ease, and without opening the pharynx. A year after the operation there had been no return of the disease. This was two years ago, and, as far as he knew, the patient is still living.

DR. CHEEVER said that the operation through the cheek is probably easier and more desirable in some cases, but the operation from the outside leaves less paralysis and less scar. The great dread of these operations was, formerly, the danger of opening the upper part of the alimentary canal and establishing a fistula. This has now been proven to be without foundation. He was inclined to think that the use of sutures in the pharynx or œsophagus would be more dangerous than their omission. The object of these operations is to permit the patients to die easier. It is more comfortable to die with an external tumor than with one pressing upon the larynx or throat, causing starvation or choking.

AFTERNOON SESSION.

DR. CLAUDIUS H. MASTIN, of Mobile, read a paper entitled

HERNIA: A COMPARISON OF THE VARIOUS METHODS ADOPTED FOR ITS RADICAL CURE.

Reference was first made to the great frequency of this condition. The census reports of 1880 show that of the total number of deaths, one in every six hundred was due to hernia, and out of twelve hundred and thirty-six deaths from hernia, one hundred and forty-one occurred in children under one year of age.

The paper concluded with the following remarks:

The ligature of the sac at its neck, with suture of the pillars, of canal and ring, may be considered an established surgical procedure. Still, being a comparatively new operation, a discussion of its merits will be of practical value in leading to further improvements, and with them, permanent success of the operation. With the present lights before us, the most important point in the operation appears to be closing of the neck of the sac as high up as possible, so as effectually to seal up the opening into the abdominal cavity. To do this completely it is necessary that the sac should be carefully separated from the adjacent tissues, and this is not always an easy matter, since oftentimes the true sac is obliterated and a new sac formed in the fibrous tissue, with the vascular and nervous distribution blended in such a manner as to render the dissection most difficult if not impossible. In such a case Macewen's operation could not be performed and it would be impossible to twist the sac as recommended by Mr. Ball. This objection does not obtain in crural and umbilical herniæ; still, since inguinal is the most frequent of the herniæ, it is of importance in them. In the congenital cases it is much easier to separate the sac and hence more possible to do a complete operation; but since in young children, the truss properly applied and long continued until the abdominal parietes have been so developed as to increase the obliquity of the canal, will, in most instances, produce a permanent cure, all operative procedures in children should be considered unwarrantable. In these cases, however, where an imprisoned testicle complicates the condition, the operation is unquestionably proper and the removal of the testicle justifiable, and for the simple reason that the presence of the gland in the canal predisposes to the descent of the hernia.

Since the main point in the success of the operation appears to have been the proper disposal of the sac, it is not astonishing that operators who have given it their attention should have adopted diverse methods, each one of which has the same end in view. Whilst Ball twists it, Macewen tucks it up; Hardee insists upon the importance of inclosing the transversalis fascia with the sac in the ligature; J. D. Bryant splits the pillars on either side and weaves in the sac; Annandale opens the canal, ties the sac, cuts it away and stitches the opening; on the other hand, Stokes opens the sac, and then, stitching the neck, the canal, and the pillars together, he leaves the sac in position; Banks opens the sac, ligates the neck, cuts away the fundus and sutures the pillars; Alexander, of Liverpool, opens the canal, ligates the sac flush with the peritoneum internally, then divides the neck below the ligature, leaving the sac in the canal without suturing the ring; MacCormac advocates this plan, while Buchanan cuts down to the sac, slits it up longitudinally on each side of the cord, divides the front part horizontally, rolls up the upper part, with which he plugs the internal ring, and turns down the lower half to form the tunica vaginalis.

From a comparison of all the methods, it is apparent that no fixed rule of procedure is established, and although the radical operation is a marked improvement in the treatment of hernia, whether free or strangulated, we cannot consider it perfected, because the methods hitherto resorted to have not proved radical in results. The operation is ideally correct, but the question arises, whether, with the uncertainty of success, the risk justifies the operation, especially so if the circumstances of the individual are such that he can content himself with the use of a properly adjusted truss.

DR. M. H. RICHARDSON said that his experience with the operation for the radical cure of hernia had been small. Sufficient time has not elapsed to permit us to say what the ultimate result will be. His preference has been for the invagination of the sac as proposed by Macewen. He did not advocate the operation in trivial cases of hernia. Here he believed that the application of a well-fitting truss is the more conservative and better plan.

DR. D. HAYES AGNEW thought that we had yet to speak with a good deal of reserve as to which is the most successful operation. Sufficient time has not elapsed to enable us to speak positively upon this subject. The operation which seemed to him most applicable is that in which the sac is ligated, pushed into the internal ring, stitched there, and transverse sutures passed across the canal. He thought that the omentum will constitute an important element in the radical cure of hernia. He believed that in all cases of strangulated hernia we are justified in attempting the radical cure. The same is true in those cases of hernia which cannot be controlled by a truss, leaving the patient exposed to great risk.

DR. W. W. DAWSON, of Cincinnati, thought that in cases in which life is not in jeopardy we should approach the operation with a great deal of consideration He had seen very different results from the same operation performed with equal care in cases apparently similar. Where life is in danger, duty impels us to operate, but where the question is one of æsthetics or abridged usefulness, the operation should be approached cautiously.

DR. L. MCLANE TIFFANY, of Baltimore, said that his operations for radical cure in cases of strangulated hernia were more successful than formerly, and attributed this to the fact that he operated now in a more cleanly manner. He thought that no operation for strangulated hernia is complete unless an attempt at radical cure is made. When the hernia is not strangulated, the question arises as to the kind of hernia, the inconvenience that it causes, and the circumstances of the individual. He did not believe that the operation *per se* is likely to be followed by much trouble. The method to be employed must be determined by the peculiarities of the case.

In regard to children, he thought that in congenital hernia, especially where it is probable that the child will have to work for its living, it is the duty of the surgeon to operate. Here it is not necessary to open the peritoneum. A ligature is thrown around the sac above and another lower down, and the intervening portion excised,

forming a tunica vaginalis below and a peritoneal sac above.

DR. D. U. YANDELL, of Louisville, believed that in strangulated hernia the surgeon should attempt the radical cure. This had been his practice and he had used various methods. It is difficult for any one man to decide which is the best operation, but in the course of ten years we shall be able to arrive at some opinion.

DR. J. FORD THOMPSON, of Washington, thought that there is very little difference in the operations. The main point is to get rid of the sac. He thought that suture of the pillars is useless. The operation that he has employed is practically that of McBurney. In strangulated hernia it seemed to him that there must be danger in inverting the sac, as in Macewen's operation. He had seen many cases of hernia in children, but had never been able to adopt the view of Dr. Tiffany. As a rule, if we can keep the intestine reduced, the hernia is cured in a comparatively short time. In some cases of large hernia in children the radical operation is probably justifiable.

DR. W. W. KEEN, of Philadelphia, said that doubtless all agreed that in strangulated hernia no operation is complete without an attempt at radical cure. It was also agreed that in those cases where the hernia is not controlled by a truss and the patient is unable to labor, radical operation is advisable. The tendency at the present time is to extend the limits of the operation beyond these two classes. The presence of hernia is always attended with risk; hence, the tendency at present is to operate on a larger number of cases. In children, if the retentive measures after a thorough trial for a few years fail to effect a cure, he should be inclined to operate.

In very large hernia he should not be inclined to use Macewen's method. The life of the sac is imperilled by separating it. In large hernia a certain amount of preparatory treatment is desirable to accustom the abdominal cavity to the presence of the intestine and thus prevent undue pressure upon the diaphragm and strain upon the sutures. In the more ordinary cases he thought that the operation of McBurney is the best. He should place the operations in the following order: McBurney's, Macewen's, and Ball's.

DR. C. H. MASTIN said that the object of his paper was to elicit discussion as to the best method of operating. He had performed 34 operations for hernia, with 3 deaths. Two of these may be excluded, as the patients were *in extremis* at the time of the operation. This leaves 32 cases with 1 death. Of this number there had been 8 radical cures. One of these cases he had watched for seventeen years. The method employed was after the sac was opened to pass a deep pin through the pillars, with an ordinary twisted suture over it, close the incision, and place the leg on a double-inclined plane. Thirty-one cases have recovered with primary union. He believed that the cure is produced by the dense cicatricial tissue formed in the canal.

DR. J. R. WEIST, of Richmond, Md., had operated on strangulated hernia 41 times. In 30 cases he had attempted to make a radical cure, using a variety of methods. In only 4 cases had he succeeded in keeping the hernia in. A number had remained well for six months to two years, and then the hernia had reappeared as bad as ever.

DR. M. H. RICHARDSON, of Boston, then read a paper on

THE SURGICAL TREATMENT OF GANGRENOUS HERNIA.

The principal question discussed was the relative advantage of immediate excision and suture of the bowel, and the formation of an artificial anus with subsequent closure. The views of various authorities were first quoted. The author then briefly reported the cases coming under his own observation.

Case I.—A young woman with right femoral hernia, strangulated for one week. Bowel was found gangrenous and excised. Death from shock the next day.

Case II.—Woman, æt. sixty-five years; left inginual hernia. On opening the sac the bowel was found strangulated and dark in color. The hernia was reduced, but the symptoms of obstruction continued, and five days later the sac was opened and the intestine found strangulated by a band within the ring. The bowel was drawn out, the strangulated portion excised, and the ends sutured. The patient died of shock.

Case III.—Woman, æt. forty-two years; had been treated by Christian scientists for five days. There was a large umbilical hernia with gangrenous intestine. The sac was filled with fecal matter. The constriction was found, and the bowel drawn out and excised beyond the constriction, and the ends united. This patient recovered perfectly and has remained well.

Case IV.—A woman with enormous umbilical hernia, with strangulation and gangrene. The fecal abscess opened by natural processes, and the woman has been in perfect health since, with the exception of the artificial anus. This will be operated on next week.

In the two cases of excision the time required for the passage of the sutures was twenty minutes; the whole operation did not exceed one hour. The longer the operation the more are the chances reduced.

Reference was then made to the use of the bone-plates of Senn and the catgut rings of Abbe. These devices may do more in these cases than anything else. Every case must be decided on its merits. The danger to life of resection in suitable cases is probably not greater than the danger of artificial anus with the dangers attending the subsequent closure of the same. The danger of the latter operation is especially great when the opening is near the stomach. Artificial anus is also objectionable on account of the excoriation of the skin which attends it, and also the risk of giving way of the sutures.

The author concluded as follows: It seems to be the general opinion of surgeons everywhere that under some circumstances excision and sutures are justifiable. It seemed to him that the primary operation should only be done where all the conditions are favorable. It is preëminently a hospital operation. Every appliance and preparation should be ready for its most perfect performance. It is not an operation to be recommended to the general practitioner or to the unqualified operator. It depends for success more often upon rapid and skilful execution than almost any other operation.

There is no doubt that in some cases this procedure is imperative, where the part necrosed is too high up for intestinal nutrition to be maintained. The difficulty, of course, is to recognize this state of things. Even when it can be demonstrated that the jejunum is gangrenous,

excision is not justifiable unless the patient's condition offers some hope, and there is a chance that the relief of the symptoms of obstruction may be followed by sufficient improvement to make a secondary operation possible.

DR. D. HAYES AGNEW said that his experience was too limited to enable him to say much upon this subject. He recalled three cases of gangrenous hernia. One was a case of inguinal hernia, in which he excised a portion of the bowel. The patient recovered from the immediate effects of the operation and passed out of his hands. Some months afterward he was advised by another surgeon to apply a compress to the external opening so as to compel nature to establish a communication between the two portions of the bowel. He did so with fatal results. The second case was one of femoral hernia which had lasted six or seven days. It was laid open and the patient recovered. As the granulations filled the opening communication took place between the two portions of bowel. The third case was one of umbilical hernia. He opened the sac, excised ten inches of intestine and carefully stiched the ends. The patient died of hemorrhage at the end of two days. It occurred to him that it would be wise in such a case to stitch the intestine to the skin, and at a subsequent period do the operation of Dr. Abbe.

DR. W. T. BRIGGS, of Nashville, said that although he had seen many cases of strangulated hernia, he had met with but three instances of gangrenous intestine. In the first case he opened the abscess and the fecal contents escaped. The patient lived some time, but died of inanition. In the second case he attached the bowel to surrounding parts and made an opening in it. The patient died in twenty-four hours. The third case he left entirely to nature and the patient recovered with an artificial anus.

DR. P. S. CONNER, of Cincinnati, had had three cases of gangrenous hernia, and had seen a fourth in the practice of Dr. Dandridge. The operation of intestinal anastomosis is valuable. It can be performed rapidly; it is simple, and establishes the continuity of the intestinal tract more perfectly than any other operation that has been suggested.

DR. W. F. PECK, of Davenport, from his experience, thought that great benefit in the way of prevention would result from educating the subjects of this trouble in regard to the dangers of hernia and the way of reduction.

DR. J. EWING MEARS, of Philadelphia, had had two cases: one of umbilical hernia, in which he made an artificial anus; the other of femoral hernia, where he performed resection, and returned the intestine to the abdomen. Both resulted fatally inside of forty-eight hours. A surgeon of Vienna has suggested that in these cases the gangrenous intestine be withdrawn from the abdomen and held in place outside by a tampon of iodoform gauze. In this way the intestine can be kept under observation and treated as seems best.

DR. W. W. KEEN thought that the introduction of the method of intestinal anastomosis by the bone plates of Senn or the catgut rings of Abbe is a great advance over former methods. The mortality following this method is greatly less than that following reunion of the ends of the bowel.

DR. T. A. MCGRAW, of Detroit, had heard nothing in regard to the pathological condition of the bowel above the seat of stricture. In some cases the bowel is healthy immediately above the point of strangulation, while in others the inflammatory process extends six to ten inches above the point of constriction. This must make a great difference as regards the results of operation.

DR. A. VANDER VEER eleven years ago saw a case of gangrenous inguinal hernia, but the condition was so bad that nothing was done. The patient died a few hours later. Two years ago he saw a similar case, except that the patient was younger and the collapse not so great. He opened freely, and left it to nature. The man recovered with an artificial anus.

DR. H. H. MUDD, of St. Louis, thought that gangrenous hernia is not so rare as seems to be the general impression. He could recall at least seven cases, three of which occurred more then four years ago, and all died. During the last four years he had operated on four cases, excising a portion of the bowel, with recovery in one case.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 16, 1889.

ANDREW H. SMITH, M.D., VICE-PRESIDENT, IN THE CHAIR.

DR. O. D. POMEROY, Chairman of the Section on Ophthalmology and Otology, on behalf of his Section presented to the Academy a fine

PORTRAIT OF THE LATE CORNELIUS R. AGNEW,

with a few eulogistic remarks which were seconded by Drs. Fordyce Baker, A. Jacobi, and H. D. Noyes.

DR. W. GILMAN THOMPSON then read a paper on

THE THERAPEUTIC VALUE OF OXYGEN, WITH EXHIBITION OF ANIMALS UNDER HIGH PRESSURE OF OXYGEN.

He said he had been impressed by the fact that while some observers claimed the most brilliant therapeutical results from the use of this agent, others hold that it was but of little, if any, practical value, and still others used it in such a vague way that no reliance could be placed upon the results obtained. As was well known, the ordinary pressure of the atmosphere was fifteen pounds to the square inch. Of this amount, three pounds of pressure was exerted by the oxygen, and twelve pounds by the nitrogen. The first question that arose was, Does an increased pressure really cause more oxygen to be absorbed? Under any circumstances the hemoglobin of the blood could take up but two and a half per cent. more of oxygen, and it was also a fact that it could not enter the plasma to any extent.

In most of the older text-books it was stated that animals could not live in pure oxygen, the system being burned up as it were by the increased tissue-changes excited by it. This idea, however, was an entire mistake, as was conclusively demonstrated by Dr. Andrew H. Smith in the series of experiments made by him in 1869 and 1870. Having referred to some of the symptoms produced in the human subject by the inhalation of oxygen, he said that very little additional oxygen could be made to enter the system by any amount of pressure short of that which would produce injurious effects.

He then exhibited the apparatus which he had had

constructed for the purpose of exposing animals to high pressures of oxygen. It consisted of a strong iron drum or chamber, with glass-covered openings at each end, in which the animal to be experimented upon was to be placed; and to this oxygen was supplied at any degree of pressure desired from a cylinder containing the gas, at a pressure of two hundred and twenty-five pounds to the square inch. Two animals, a monkey and a pigeon, which had been exposed for one hour to a pressure of thirty pounds to the square inch, oxygen, in addition to the ordinary pressure of the atmosphere, fifteen pounds to the square inch, were taken from the drum in an apparently perfectly normal condition.

Dr. Thompson next proceeded to make a detailed report of a number of experiments he had made upon animals which were in a normal condition at the time the experiments were commenced; the animals being dogs, cats, pigs, monkeys, guinea-pigs, pigeons, and alligators. It was found that all the animals could exist comfortably in the oxygen until a pressure exceeding three atmospheres was employed. The higher orders of animals were affected before the lower ones. As a rule, a decided fall of temperature, often amounting to from 4° to 6°, was observed; and only in cold-blooded animals was there any rise in temperature. This marked decrease in temperature he did not believe was to be attributed at all to the effect of the oxygen, but to the profound disturbances in the system caused by the high pressure employed. If, as was claimed by the older writers, a greatly increased tissue-metamorphosis was caused by oxygen, this would unquestionably be accompanied by an increase, and not a diminution, of the body temperature. In a paper read before the Royal Academy of Madrid, Valenzuela reported similar results. In animals subjected to oxygen in a pneumatic chamber under increased pressure, he found that the temperature was reduced several degrees, and rabbits in which septicæmia had been artificially produced, had the temperature reduced to normal.

In such of the animals as died as a result of subjection to high pressure of oxygen, or were killed after removal from such pressure in the pneumatic drum, Dr. Thompson found pulmonary engorgement and dilatation of the right heart. The convulsions which usually resulted when the pressure was carried to a high point, were, as a rule, quickly controlled by blowing off five pounds of pressure. He also tried the experiment of subjecting animals on alternate days to high pressure of oxygen and to compressed air, the series of observations being maintained for a considerable period. The cause of the convulsions produced by exposure to high pressure of oxygen he said was as yet undecided, but he was inclined to attribute it to the difference in the diffusion of oxygen and carbon dioxide under different degrees of pressure.

A second series of experiments was performed upon animals in which abnormal respiration had been induced. Dyspnœa might be classified as follows:

(1) That due to abnormal conditions of the air.
(2) Due to abnormal conditions of the blood.
(3) Due to obstructed circulation.
(4) Due to diminished surface from aëration.
(5) Due to neurotic influences.

In a cat in which dyspnœa was produced by cutting both vagi instant relief was given by exposing the animal to oxygen; while, on the other hand, the dyspnœa was increased by compressed air. In the second experiment a canula was introduced into the pleura of a dog. In the third pulmonary congestion was caused in a cat by injecting a solution of nitrate of silver into the lung-tissue, and the dyspnœa resulting therefrom was greatly relieved by oxygen. In other experiments the lung was compressed by injecting considerable quantities of water into the pleura, and in still others the animals were bled to the extent of many ounces. The results of these experiments, he said, went to show that oxygen does aid, in a moderate degree, certain types of dyspnœa.

In considering the therapeutic value of oxygen it was to be borne in mind that it was a physical impossibility to take oxygen into the blood. This agent had been employed, first, as curative in certain diseases of the blood and circulation, and, second, as a palliative in dyspnœa due to various causes. Of late, its use has increased to such an extent that two or three hundred thousand gallons of it were now consumed annually in New York City alone. Among the affections, in addition to dyspnœa from whatever cause, in which it was claimed that it had proved of benefit, were anæmia, chlorosis, croup, chronic gastric catarrh, migraine, cholera, and opium narcosis. It was used more generally in this country and on the Continent of Europe than in England. In Paris a supply was kept on hand at the stations along the Seine for use in resuscitating persons rescued from the river, and also at some of the fire and police stations.

In anæmia, chlorosis, etc., Dr. Thompson said he could see but little advantage over good fresh air in giving diluted inhalations of oxygen two or three times a day, as was the usual practice in such affections. It did not seem rational to him to expect that sufficient oxygen could enter the system, under these circumstances, to produce anything but a temporary effect. In cases of blood-poisoning, again, he had failed to see any relief afforded by oxygen. In certain subjective cases of dyspnœa it might relief, but in a case of poisoning by illuminating gas, which he had seen at the Presbyterian Hospital, it was kept up for nearly three days without any effect either on the rate of breathing or on the cyanosis present. In cardiac diseases his experience with oxygen had not been encouraging, and he referred particularly to a case of malignant endocarditis, in which it proved of no avail in relieving the dyspnœa. In certain cases of asthma and of uræmic dyspnœa, however, it gave decided relief, and in such he believed it was an invaluable therapeutic agent; though not, of course, curative.

DR. J. WEST ROOSEVELT spoke of the relation of the oxygen inhaled to the amount of oxygen absorbed, and said that while the amount which entered the plasma or the hemoglobin of the blood was comparatively small, he believed it was sufficient to cause appreciable results in many instances. As to the therapeutic value of oxygen, in the neurotic form of dyspnœa we had a condition in which the mere act of inhalation and the engaging of the attention of the patient would often have a beneficial effect. With oxygen in anæmia he had met with fairly good results, though the patients improved less rapidly than under the use of iron. If in any case the hæmoglobin was not saturated an improvement showed that more oxygen was carried than under ordinary circumstances. In his experience oxygen had proved of

considerable value; and in cases of diminished surface for aëration he had seen cyanosis decidedly improved under its use.

DR. GEORGE L. PEABODY said that so many circumstances were involved in estimating the value of an agent like oxygen that it was difficult to arrive at positive conclusions respecting it. Thus, when it was not the only therapeutic agent employed, it was impossible to say just how much benefit was derived from it; and this difficulty was increased in diseases which naturally tend to recovery. The question of the utility of oxygen, he believed, was still undecided. When the idea of its administration first occupied the profession it was the practice to give internally chemical substances, like chlorate of potassium, for instance, which were known to be rich in oxygen. It was far from certain, however, whether they yielded up their oxygen on entering the body; and even if this were so, it seemed probable that the resulting compounds might have a more or less caustic effect upon the tissues. This was apparently the case with osmic acid.

Later, it had become the practice to give oxygen by inhalation so that it would come directly in contact with the lungs. Its absorption depended probably on the amount of hæmoglobin in the blood at the time the oxygen was inhaled, but in any event the amount absorbed was unquestionably small. There was good reason to doubt the alleged efficiency of this agent, and personally he believed that just as much relief, as a rule, could be obtained from fresh air. It might be tried, however, in maladies attended by dyspnœa in which the blood is unchanged, such as pneumonia, emphysema, croup, and asphyxia from toxic gases; although, as Dr. Thompson had said, in poisoning from illuminating gas it had failed to give relief. There was no justification, he thought, for the extensive use of oxygen in general diseases, such as anæmia, chlorosis, gout, lithæmia, etc. Although the pulmonary gymnastics of the inhalations might have a beneficial effect in certain instances, there were other remedies which could be used with much greater advantage. That the use of oxygen hastened recovery in such diseases he did not believe, and the recognized facts of physiology were at variance with any such conclusion.

DR. BEVERLEY ROBINSON said that he differed entirely from Dr. Peabody, and that his clinical experience in many conditions afforded the most conclusive proof of the immediate and marked relief resulting from the use of pure oxygen. In anæmia he had found that those cases were most improved in which oxygen was used in connection with iron. The purity of the gas was a point of the utmost importance, and he said that a gas which he had formerly employed gave such poor results that he ceased to use it, There was a gas now manufactured in New York which was said to contain a certain amount of nitrogen monoxide; and it was worthy of note that Brown-Séquard had expressed the opinion that nitrogen was of great service in preventing the irritating and intensely exciting effects of oxygen alone.

In albuminuria connected with atrophic nephritis he had found the general nutrition of the patient notably improved under the use of oxygen; the digestive and assimilative powers being greatly assisted by it. Even in phthisis, while it did not have curative effect, it might prove beneficial. In the first place, the inhalations caused the patient to expand his lungs thoroughly; secondly, oxygen was itself an antiseptic, and, therefore, indicated; and, thirdly, it had the effect of improving the general nutrition. As had been well said, oxygen was really prescribed every time that a patient was sent to the mountains, to Southern California, to the plains, or on a sea voyage. But there were many cases in which it was impossible to send patients away, and he believed it was possible to stimulate the hæmoglobin in the blood, and thus enable the patient to carry more oxygen. In the use of such agents as oxygen he did not think we should be guided so much by experimental researches as by practical clinical experience. Without considering the curative effects of oxygen, there were certainly many cases where the last hours of patients could be rendered much more comfortable by resorting to its use.

DR. WALTER MENDELSON said that he felt compelled to concur with Dr. Peabody from what he had observed of oxygen. In anæmia, it was true, he had seen marked results under its use, but he did not believe that the benefit was due to this agent. He cited the case of an old man who inhaled ten gallons of oxygen a day, and became greatly improved. This improvement, however, he was convinced, was due to the systematic expansion of the lungs and to the moral effect of the knowledge that something unusual was being done for him. In cases of dyspnœa from various causes he had seen more or less relief afforded by oxygen; yet all the patients died. Still, as Dr. Robinson had said, their last moments may have been rendered more comfortable by the inhalations.

DR. MARY PUTNAM JACOBI said that the amount of oxygen which the hæmoglobin carries varies under different circumstances. In asphyxia of various kinds the physiological capacity remains the same, and, therefore, the indication is to administer oxygen. The correctness of this has also been shown by clinical experience. In anæmia, and especially chloro-anæmia, on the other hand, the hæmoglobin is diminished. The condition is precisely the reverse from that met with in asphyxia, and we cannot cause a much greater amount of oxygen to be absorbed.

DR. ANDREW H. SMITH was gratified to learn that the work which he did twenty years ago in the main still stands good. At that time he had demonstrated that animals could live perfectly well for four days in pure oxygen, care being taken to remove the effete products of respiration. It was his opinion that under ordinary conditions the blood is not fully saturated with oxygen, and that the point of saturation corresponds with the physical demand. This allowed a pretty wide margin, and it was perhaps within this margin that a considerable amount of oxygen could be absorbed by the blood. Thus the demand for oxygen was much greater in athletes engaged in violent physical exercise than in individuals making but little physical exertion. Therapeutically he had seen the greatest benefit received from oxygen in catarrhal conditions of the air-passages, such as was met with in suffocative bronchitis. In such cases he was at a loss how to explain the relief afforded by the oxygen, unless it was a fact that under these conditions the blood does not take up as much oxygen as the system requires. When pneumonia was present so many conditions were brought into play that the matter was

much more complex, and the relief afforded by oxygen very uncertain. Dr. Smith also said he had used oxygen with satisfactory results in opium poisoning.

Dr. Thompson, in closing the discussion, said that convulsions were produced in the animals experimented upon by the rapid increase of the pressure, and that such convulsions were quickly relieved by the rapid withdrawal of a portion of the pressure. He could not agree with Dr. Smith in his opinion regarding the saturation of the blood with oxygen, since he thought there could be no question that even under ordinary conditions the hæmoglobin is practically saturated with oxygen. In reply to Dr. Roosevelt he said that many individuals suffer from dyspnœa whose blood contains more oxygen than that of those with anæmia or suffering from hemorrhages. Dr. Robinson was certainly mistaken in attributing any irritating effects to oxygen. Pure oxygen had no irritating effects whatever, as had been repeatedly demonstrated. It produced no burning up of the tissues at all, as had been formerly supposed, and he could see no advantage of the nitrogen monoxide referred to over ordinary air.

CORRESPONDENCE.

ANTIPYRIN A CONTRA-INDICATION IN MENSTRUATION.

To the Editor of The Medical News,

Sir: Your extract from report of Dr. H. Huchard, in The Medical News, February 23, 1889, page 215, I believe is valuable rather as showing peculiar susceptibility to antipyrin on the part of Dr. Huchard's patient, and perhaps over-dosage, than as demonstrating any danger in administering antipyrin in dysmenorrhœa in proper doses. Was not the stopping of the menstrual flow due rather to the disturbance of circulation than otherwise? I have given antipyrin for over two years to nearly every case of dysmenorrhœa coming under my care and with complete relief in nearly every instance and no diminution of menstrual flow. But I seldom find more than ten grains necessary and oftener find five grains sufficient, always beginning with the latter dose.

I believe it is a very valuable drug and capable of much good in much smaller doses than usually recommended, especially in dysmenorrhœa; anyone who will try will be surprised how many cases of dysmenorrhœa and wearing pains during first stage of labor will be relieved by five grains repeated as needed.

I have some reason to fear that its continued use blackens the teeth.

H. G. Norton, M.D.

Trenton, N. J., April 29, 1889.

NEWS ITEMS.

The American Laryngological Association.—The following is the programme for the Eleventh Annual Congress of this society, Washington, on May 30th and 31st and June 1st:

"Report of the Removal of a Supernumerary Tonsil: Specimen and Drawings." By E. Carroll Morgan, M.D., of Washington.

"An Œdematous Form of Disease of the Upper Air-passages." By Wm. C. Glasgow, M.D., of St. Louis.

"The Relation between Facial Erysipelas and Erythema on the one hand, and Intra-nasal Pressure on the other." By George W. Major, M.D., of Montreal.

"Acute Multiple Adenitis (Septic?); Œdema of the Larynx, with Spontaneous Cure; Laryngoscopic Appearances." By Samuel W. Langmaid, M.D., of Boston.

"Some Points in the Pathology and Treatment of Diseases of the Nasal Pharynx." By John N. Mackenzie, M.D., of Baltimore.

"Observations upon the Condition known as Adenoid Hypertrophy at the Vault of the Pharynx, and the Methods used for its Relief." By D. Bryson Delavan, M.D., of New York.

"Three Rare Cases. Illustrated." By George M. Lefferts, M.D., of New York.

"Warts in the Nasal Passages." By E. Fletcher Ingals, M.D., of Chicago.

"Some of the Manifestations of Syphilis of the Upper Air-passages." By T. Amory De Blois, M.D., of Boston.

"Note on the Galvano-cautery in the Treatment of Hypertrophied Tonsils." By Charles H. Knight, M.D., of New York.

"The Treatment of Diseased Tonsils when unattended with Hypertrophy." By John O. Roe, M.D., of Rochester.

"Experimental Methods of Studying the Actions of the Intrinsic Muscles of the Larynx." By Franklin H. Hooper, M.D., of Boston.

"Dysphonia Spastica." By Frederick I. Knight, M.D., of Boston.

"A Case of Sarcoma of the Thyroid Gland; pressure on the right sympathetic nerve; unilateral tonic spasm of laryngeal muscles; intermittent clonic spasm of opposite side; compression stenosis; tracheotomy; hemorrhage from gland twenty months later; pressure upon the left sympathetic nerve; death from disturbance in the functions of the two sympathetics." By J. Solis-Cohen, M.D., of Philadelphia.

"Memorandum of a Recurrent Laryngeal Growth, appearing Twenty-two Years after Removal." By Rufus P. Lincoln, M.D., of New York.

"Some Unusual Manifestations of Tuberculosis of the Larynx." By Clarence C. Rice, M.D., of New York.

"Report of Two Cases of Tuberculosis of the Tongue." By C. E. Bean, M.D., of St. Paul.

"The Advantages of Occasional Applications of Silver Nitrate in Chronic Laryngitis." By S. Solis-Cohen, M.D., of Philadelphia.

"Some Manifestations in the Throat of Lithæmia and Allied Conditions." By F. Whitehill Hinkel, M.D., of Buffalo.

"On the Local Treatment of Diphtheria." By J. C. Mulhall, M.D., of St. Louis.

"Hemorrhage from the Larynx." By Wm. Porter, M.D., of St. Louis.

The profession is cordially invited to attend the sessions of the Association.

The Johns Hopkins University.—The departments of pathology and biology at the Johns Hopkins University have been combined and will be called the department of Normal and Pathological Biology, with Professors

Martin and Welch at the head, assisted by Assistant Professors Brooks, Howell, and Councilman and Drs. Andrews and Mall. Those working in this department may take any or all branches, but the object of the arrangement is evidently to compel students to study normal biology first and pathology last. Under the first head will be included physiology, histology, morphology, and botany, and in pathology will be included gross and microscopical pathology, experimental pathology, and bacteriology.—*Maryland Med. Journal*, May 11, 1889.

Resolution on Dr. Keen's Retirement from the Woman's Medical College.—At a stated meeting of the Faculty of the Woman's Medical College of Pennsylvania, held May 18, 1889, the following resolution was offered:

"*Resolved*, That the Faculty of the Woman's Medical College of Pennsylvania have learned with deep regret of the resignation by Professor W. W. Keen of the Chair of Surgery in this College.

"Dr. Keen's enthusiasm as a teacher in a department for which he is eminently qualified, and his unhesitating surrender of time in doing a generous share of Faculty work, has made his connection with the College conspicuously valuable and helpful.

"The Faculty also desire to express their sense of personal loss in this severance of relations which have ever been most harmonious and agreeable, and to proffer their congratulations to Dr. Keen in view of his new appointment with warmer wishes for success and happiness in his future work."

Prof. Billroth's Sixtieth Birthday.—On May 6th, at 9 o'clock, Prof. Billroth commenced his clinical lectures for the present summer semester, and the opportunity was taken by his pupils and colleagues to give him a splendid ovation. The entrances to the clinic were decorated with flowers, and his working cabinet was almost transformed into a garden. Two hours before the beginning of the lecture the theatre was filled to the roof with students. At nine o'clock came the members of the committee of the "Billroth Feier," and those professors of the Vienna Medical Faculty who were not prevented by their duties from being present. There were present among other distinguished persons, Prof. Böhm, director of the Vienna General Hospital, and Profs. Lang, Fuchs, Kahler, Schnitzler, Chrobak, Dittl, and Frisch, etc. Of Billroth's former pupils, there were Prof. Wölfler, of Gratz, Prof. Mikulicz, of Königsberg, and Prof. Gussenbauer, of Prague.

At nine o'clock, Prof. Billroth, accompanied by his two present assistants, Dr. Salzer and Dr. von Eiselsberg, appeared in the theatre, and was received with a tempest of applause. An address was presented in the name of the students, to which Prof. Billroth replied in a speech in which he gave a sketch of the development of the medical sciences since the reign of the Empress Maria Theresa. He also alluded to the part which surgery had to play in the future, stating that its first task would be to get rid of tuberculosis. Among the first to congratulate Prof. Billroth at his own house was the Servian minister, Dr. Gjorgewitch, an old pupil, who presented him with the Grand Cross of the Servian St. Sava Order.

Among the numerous presents was a picture representing Billroth's famous teacher, Bernard von Langenbeck, in the middle; around this central figure are the gymnasium and University of Greifswald, the hospital and aula of the University of Göttingen, the University and Bethanien Hospital of Berlin, the University of Vienna, the Rudolphiner Hospital of Döbling (near Vienna), the Austrian House of Lords, the General Hospital of Vienna, and Billroth's house.

The medal presented to Prof. Billroth by the students bore on the obverse the words: *Theodorus Billroth ætatis suæ LX*, with a portrait of the professor; on the reverse the words *Medico artifici pietate conjuncti discipuli et sodales*. A torchlight procession, which was arranged by the students for this evening, was forbidden by the police, probably in consequence of the recent tramcar riots.—*The British Med. Journal*, May 11, 1889.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 14 TO MAY 20, 1889.

By direction of the Acting Secretary of War, a Board of Medical Officers, to consist of: ANTHONY HEGER, *Colonel and Surgeon;* F. C. AINSWORTH, *Captain and Assistant Surgeon;* and JOHN O. SKINNER, *Captain and Assistant Surgeon*, will assemble at the U. S. Military Academy, West Point, New York, about June 1, 1889, to examine into the physical qualifications of candidates for admission to the Academy and members of the graduating class.—Par. 9, *S. O. 108, A. G. O.*, May 10, 1889.

By direction of the Acting Secretary of War, the following-named officers are detailed to represent the Medical Department of the Army at the annual meeting of the American Medical Association, to be held at Newport, Rhode Island, on the 25th of June, 1889: SAMUEL M. HORTON, *Major and Surgeon;* JOHN S. BILLINGS, *Major and Surgeon;* CHARLES SMART, *Major and Surgeon.*—Par. 15, *S. O. 110, A. G. O.*, May 13, 1889.

By direction of the Secretary of War, the leave of absence granted to AARON H. APPEL, *Captain and Assistant Surgeon*, in S. O. 38, April 16, 1889, Division of the Missouri, is extended twenty days.—Par. 2, *S. O. 114, A. G. O., Washington*, May 17, 1889.

By direction of the Secretary of War, leave of absence for four months, with permission to go beyond sea, is granted WILLIAM STEPHENSON, *Captain and Assistant Surgeon.*—Par. 15, *S. O. 114, A. G. O., Washington*, May 17, 1889.

By direction of the Acting Secretary of War, leave of absence for six months, on surgeon's certificate of disability, is granted R. G. EBERT, *Captain and Assistant Surgeon*, and E. B. MOSELEY, *Captain and Assistant Surgeon.*—Pars. 5 and 6, *S. O. 109, A. G. O.*, May 11, 1889.

By direction of the Acting Secretary of War, LOUIS S. TESSON, *Captain and Assistant Surgeon*, is relieved from duty at Watervliet Arsenal, New York, and ordered to Fort Sidney, Nebraska Territory.—Par. 9, *S. O. 109, A. G. O.*, May 11, 1889.

GORGAS, WILLIAM C., *Captain and Assistant Surgeon.*—Now on duty at Fort Barrancas, Florida, will report in person to the commanding general Department of the Missouri, for temporary duty with troops in the field.—Par. 1, *S. O. 112, A. G. O, Washington*, May 15, 1889.

GORGAS, WILLIAM C., *Captain and Assistant Surgeon.*—Will accompany the command from Fort Barrancas, Florida, and proceed with Battery "H," Second Artillery, to Fort Adams, Rhode Island, and to return to his proper station on completion of this duty.—Par. 5, *S. O. 108, Headquarters Division of the Atlantic, Governor's Island, New York City*, May 13, 1889.

RAFFERTY, OGDEN, *First Lieutenant and Assistant Surgeon.*—Is granted leave of absence for one month.—Par. 3, *S. O. 29, Headquarters Department of Texas, San Antonio, Texas*, May 13, 1889.

KEAN, JEFFERSON R., *First Lieutenant and Assistant Surgeon* (Fort Robinson, Nebraska Territory).—Is hereby granted leave of absence for one month, to take effect between the 1st and 15th of June, 1889, with permission to apply at Headquarters Division of the Missouri, for an extension of fifteen days.—Par. 2, *S. O. 48, Headquarters Department of the Platte*, May 13, 1889.

INTESTINAL ANASTOMOSIS.[1]

BY ROBERT ABBE, M.D.,

SURGEON TO ST. LUKE'S HOSPITAL, NEW YORK; PROFESSOR OF CLINICAL SURGERY IN THE POST-GRADUATE HOSPITAL.

ABOUT three years ago a lady came to me from the South with a fecal fistula in the right groin, resulting from the sloughing of five inches of intestine in a strangulated hernia. Three physicians had made intelligent operative efforts to close it, and left her only worse off, as the distal end had slipped back and been lost in the abdomen. The case was a challenge to surgical skill. During several months I made careful and conscientious attempts to cure her. At first, the abdomen was opened to search for the distal end; it could not be found. Therefore, I stitched the proximal end and the ascending colon side by side in the wound, and a few days later opened the colon. A permanent channel was thus established between ileum and colon, when the fistula was capped, and some movements occurred *per anum*. Dupuytren's enterotome was then applied, and the spur cut through for two and a half inches. Still the big fistula leaked most of its contents. Two elaborate plastic operations were then done, using the abdominal skin after the manner of Czymanowski, by which I had closed urethral fistulæ. But these proved futile, and she remained with the usual excoriated abdomen, filthy wound, and marasmus. My colleague, Dr. McBurney, then tried a partial resection of the edges, with inversion and suturing, and from this operation she died.

I have narrated briefly this case to illustrate a considerable class of sufferers whose fecal fistulæ until very recently have baffled the surgeon. Such cases rankle in our memory as marking the limit at which successful work comes to a halt. To-day, thanks to the untiring energy and genius of Dr. Senn, of Milwaukee, such, and many other cases, can be offered the hope of immediate relief by intestinal anastomosis.

The principle of intestinal anastomosis is by no means new. It is on the technique of operative procedure only that its appeal to renewed favor rests. I need not narrate the methods formerly in vogue to restore the intestinal canal. Plastic operations, resections with circular enterorrhaphy, and lateral apposition with suturing, have had a certain value for many years; the unanswerable objections to them all being a dangerous consumption of time, frequent leakage, and secondary abscesses. With Senn's researches, new life has been infused into this branch of surgery. I will not review his work; it covers the ground of experimental production of intestinal flexion; volvulus, stenosis, invagination, and resection, and in reparative work the study of two methods of restoring the intestinal canal—lateral implantation of a smaller into a larger gut, and lateral apposition of openings into similar portions of bowel. The outcome of it all has been an anastomosis of an interrupted intestinal canal by the safe and speedy method of using decalcified bone plates for approximation. I believe the value of this method will soon be recognized everywhere. His experiments have already been repeated by several and the results uniformly verified.

Those done by Mr. F. B. Jessett and Victor Horsley, and reported six weeks since to the Royal Medical and Chirurgical Society, are noteworthy. Jessett adds his statistics to those of Senn and Curtis, and finds that approximation by the Czerny-Lembert method showed a mortality of about 86½ per cent. against 25 per cent. by the method of lateral implantation, and 7½ per cent. by Senn's bone approximation disks. A method which thus offers an advantage ten times as great as the old one in mortality, and that can be done in one-third or one-quarter of the time, may well inspire enthusiasm.

The application of this principle to man has as yet been limited. Dr. Senn has in six cases applied the plate method in gastro-enterostomy for cancer of the pylorus, with results detailed in four of them in his *Intestinal Surgery*. The two recently done were also successful. Dr. Fenger, of Chicago, and Dr. Hunter, of Minneapolis, have also used them. Successful each in one case. Dr. Ransohoff, of Cincinnati, operated December 31st for gastro-enterostomy by plates in a case of malignant pyloric stenosis with excellent success. An extended search fails to find other recorded cases.

My own experience includes some experiments on dogs, and two successful applications to the human subject. The man whom I first operated on lived three and a half months after I united his ascending and transverse colon by Senn's plates on either side

[1] Read before the Philadelphia County Medical Society, May 8, 1889.

of a malignant stenosis of the hepatic flexure of the colon. His case has been fully reported in the *New York Medical Journal*, March 23d last. The essential points of the case were, progressive obstruction, enormous fecal accumulation, marasmus, and finally collapse—relieved by a colotomy done when he was *in extremis*, and followed six weeks later by colo-colostomy with Senn's plates, Nov. 14, 1888. After this he rapidly gained, and in three months was enjoying excellent health. Suddenly there ensued a painless diarrhœa that could not be checked. Rapid emaciation and death followed in twenty days. Autopsy showed that nature had made an artificial opening between the duodenum and transverse colon at the site of malignant stricture. Thus all the small intestine had been excluded, and food passed practically from his stomach directly into his colon undigested; and starvation followed. The specimen obtained shows perfectly the aperture between the portions of colon. It is an oval, the long diameter of which is an inch and a quarter; nearly as long as the incision made three months before. It shows there is little to be feared from the contraction of the opening, and it also shows that an opening very much smaller than the diameter of the bowel is competent to allow one part to empty into another. I would have been very glad to be able to make a larger opening, but this was about the maximum possible by using Senn's plates. The patient had had daily evacuation of the bowels, but it had been half the time through the use of mild cathartics. A larger opening would have obviated the use of these.

The needs of this case, coupled with the fact that I had not been able to get large enough plates to suit the colon, and that the preparation of decalcified bone plates consumed several days and considerable labor, led me to review the ground that had been gone over to get a more available material. I was aware that almost every known soluble substance had been tried, including cartilage, which Jobert and others had used. I devised a ring of rubber, made in segments fastened by catgut which would fall apart after a few days, but abandoned that when I made a stiff one entirely of catgut, which, being wholly digestible, would accomplish what the plates of bone would and then disappear. I made some small sets and tried them on a dog, with the assistance of Dr. Weir and Dr. B. Farquhar Curtis. Beautiful results were obtained in two specimens. When the gut was cut, the ends were invaginated and sutured by continuous Lembert stitch. The two ends being laid side by side, a longitudinal cut was made in each near its end, a ring slipped into the gap in each, and four sutures on the ring stitched through the edge of the gap. The corresponding threads now being tied, pulled the two rings together, and the edges of the opening were thus sandwiched, as it were, between two rings. Four extra silk stitches were added outside to prevent the lips of the cuts puffing out between the first threads.

The proof of the security of apposition is seen in the dog's recovery. Evacuations were free and regular after the operation, and each of the specimens was taken out with the dog in perfect health nine days after the operation. The union was so perfect that the intestine would have burst elsewhere sooner than have given way at this place. The catgut had entirely gone; a few of the silk threads that held them were yet loosely hanging in the puncture points, ready to come out on slight pulling. The coils of approximated gut, though performing their functions well, showed considerable contortion, and in two later experiments I turned the divided ends to look in opposite directions with better result. These were done on the same dog at the same time, and were made to show a class of physicians the advantage of this method where multiple resections of the gut might be called for, as in gunshot wounds. Four inches of intestine were cut out at each place and the catgut apposition rings applied, the ends being reversed. The result has been perfect. A very large aperture of communication was obtained by the long narrow ring, which so easily slips into the bowel. The twisting of the adherent coils was not nearly so much as in the former case. I am convinced that by the two expedients of using long narrow apposition rings to obtain a large opening, and by placing the intestines as suggested, to obtain continuous peristaltic wave, we obviate a temporary blocking of the operated part which must obtain with the bone plates and small openings, and which leads to much twisting.

In this experiment it took exactly fifteen minutes to resect and complete each apposition. This includes a continuous outside silk suture around the circumference of the ring, which was applied quicker than half the number of interrupted sutures could have been.

An opportunity now came to put in practice the method above described.

In November last a woman of slight build and thirty years old came under my care at St. Luke's Hospital, with a history of uterine disorder for two years, and presenting a small tumor in the right iliac fossa. She had vomited, become anæmic, suffered much local pain, and had developed night-sweats with slight hectic. Pyosalpinx was diagnosed and operation advised. A five-inch median cut was made above the pubes. The diseased mass with omentum and coils of small intestine intimately adherent, was found to be a suppurating ovary as large as a goose-egg. Some intestines were stripped off, others seemed too firm. One of my assistants, a

distinguished disciple of Mr. Tait, being asked to examine to see whether the tumor could be removed, or whether it had best be scraped out and drained, succeeded, while examining, in digging the ovary from its bed, after the manner of Tait, who says no tumor of this character need ever be left, no matter how firmly adherent. I was surprised and delighted to be shown that this mass could be thus removed by the fingers. Notwithstanding that the suppuration had been disseminated in the wound, it was readily douched away by copious hot water effusions; but great chagrin followed the immediate discovery that a circle more than an inch in diameter had been torn from the side of an adherent loop of intestine and was on the tumor. Feces appeared at once in the deep cul-de-sac of the pelvis. I promptly found and sutured the damaged bowel, irrigated and applied a tamponade of iodoform gauze lightly, and closed the wound except for drainage. Two days later feces welled up in the wound, and a horrible, and, I feared, a hopeless fecal fistula was thenceforth established.

During the following six months the patient passed through not only the suffering incident to her fecal fistula, but also a severe attack of scarlet fever with acute desquamative nephritis. And when I returned to hospital duty I found her emaciated and weighing less than seventy pounds. Her abdominal wound healed, except over the pubis, where a long funnel-shaped wound, lined by poor granulations, gave vent to her entire fecal discharge, which came from the depths of the pelvis. The skin about it was sadly excoriated, and too tender to allow adhe sive straps to retain dressings. She was of a cheerful disposition, and hopefully looked to me to relieve her, even at the risk of life, which had become a burden. With the picture in my mind of the intestines matted together, and in the midst of all a portion whose lumen was destroyed, from which feces poured, in the site of the ovarian abscess, I looked upon the case with grave doubt of cure. The more so, because she had been subject to a hectic, with daily exacerbation of temperature to 102° and 103° up to the day of operation. My experiments with intestinal anastomosis, however, gave hope, and on March 22d—six weeks ago—I operated. Ether anæsthesia was used, notwithstanding she had five per cent. of albumin in her urine.

I dissected out the cicatrix around the funnel-shaped fistula, and opened the laparotomy wound upward. The intestines in the entire lower abdomen were matted firmly together, and uniformly studded with miliary tubercles. The pathologist's report confirms this, and I presume the original ovarian mass was a tubercular ovary, though I regret to say it was mislaid at the operation. With great care the intestine leading to the fistula was dissected out on either side of it for four inches, and cut squarely across. The ends were then turned in for half an inch and closed by a single row of continuous Lembert sutures of fine black silk. It was impossible here to turn the ends in opposite directions, and they were laid side by side, split open longitudinally for an inch and three-quarters, nearly to the end, and united with catgut apposition rings, with a half-dozen reinforcing silk stitches outside. The entire wound was douched liberally with hot water, and a portion of the deeply adherent gut between the cut ends was further dissected away. The wound was closed, except for a light tamponade of gauze at the site of the fistula.

The patient rallied nicely, had no pain whatever afterward, and no feces came into the wound. She had a little vomiting the next day, but retained koumys and champagne, an ounce every two hours, in drachm doses. At the end of the fourth day, her temperature having risen to 102°, I gave liq. magnes. citrat. ℥jv, and repeated. Three natural and painless movements passed by the rectum for the first time in six months, and her temperature fell to 100°. Daily movements took place from that time on, at first assisted by four ounces of magnesia every third day. The wound granulated nicely, and no feces have ever appeared there. The patient walked about after the fourth week, and is restored in appetite and health. She now gains three pounds weekly, is free from pain, and is making a happy convalescence. Her evacuations are normal and regular, well formed, and occur without the use of medicine.

Thus is completed a proof of the efficacy of a new method, treating a malady which I know of no other method as competent to cope with. I can hardly conceive of a fecal fistula in any part of the bowel (except, perhaps, low in the rectum) that may not be safely cured by this method, provided the distal portion is not blocked by disease. In cases of gangrenous hernia, bullet or other wounds requiring exsection of a portion of the bowel, it may be applied at once, or after an artificial anus is established and the patient is convalescing. No surgeon or physician need hesitate to make a fistula to relieve obstruction, or in other suitable cases where the equipment to complete the immediate anastomosis is not at hand, or where the patient's condition will not endure much interference, as in the first case narrated.

Two weeks ago my friend, Dr. Charles McBurney, applied a set of my catgut rings to a case of gastro-enterostomy, and writes as follows:

"The case was one of cancer of the pylorus which caused total obstruction. The patient would not consent to an operation until he was nearly moribund. The anastomosis was made between the highest part of the jejunum and the anterior of the stomach, near the greater curvature, and about three inches from the pylorus.

"The operation was perfectly easy and rapid, and the rings acted perfectly. The whole operation took forty-five minutes, much time being lost on account of imperfect washing of the stomach beforehand. I think it could easily be done inside of thirty minutes.

"Death occurred from inanition about twelve hours later. On careful post-mortem test, the stomach being filled with colored fluid and held up, absolutely no leakage at the site of operation occurred."

To make the rings most efficiently the following steps must be observed: A moderately heavy catgut

is chosen; taken from alcohol or juniper oil, it is wound loosely on a test-tube and soaked in hot water. It soon kinks up, and, were it not on a tube, could hardly be unravelled. After a while it is straightened out, allowed to untwist, wound again loosely, and soaked in hot water once more, until it ceases to twist. It is then ready to make up into rings, which will lie perfectly flat. Eight or ten turns over two pins stuck in a cork two inches apart, will make a bundle somewhat smaller than a lead pencil. These may be tied at four places with fine silk, to secure the strands parallel while being wound round like a cable, with a continuous piece of the same catgut. The end of the piece is secured by threading it into a Hagedorn needle, and transfixing the whole bundle obliquely with it at the place of finishing. Thus there are no knots, and it is difficult to find the point of beginning.

The ring is now a long oval with an inside diameter of two inches, and in thickness smaller than a pencil. Six strong but small braided silk threads are now fixed to each ring, equidistant, on the face looking toward the other ring which is to be laid against it. No knots are used. A needle pierces the ring between the strands, carrying the thread, which is drawn through all but eight inches, and wound once and a half round, sinking between the encircling catgut, piercing the ring again, and cut off. The rings, which have now been water-soaked, are ready for use if needed for emergency; but, if possible, they should be kept awhile in alcohol, under pressure between two glass slides, the threads being curled up within the oval, and the sides being pressed together after the glasses are tightly tied together. The ring thus becomes a long oval with parallel sides, and soon becomes harder and flattened on its faces. Moreover, it shrinks a trifle in alcohol, to swell again in the intestine and give additional security.

In using the rings, I find it saves time to have each thread have its own needle. The intestine is pierced from within outward less than a quarter of an inch from its cut edge. The ring should be laid on a damp folded towel with threads in order and needles stuck in the towel, which is held by the assistant close to the bowel, while the operator quickly pulls the threads through and passes the ring into the interior of the bowel. When the threads are tied and cut off, the apposition is perfect, but by a quickly made running suture outside all, a half inch of peritoneal surface is at once secured beyond the possibility of leakage. More than this is superfluous, for the edges held between the rings act as valves.

In invaginating the end of the cut intestine after exsection, one will delay a long while if he tries to turn in first one and then the other edge, and will also find the mesentery try to turn in after it on the attached side. My rule is to trim back the mesentery at least a half inch from the end. Then seizing both lips with toothed forceps, plunge them directly into the lumen. The entire edge usually follows, and one holds them by the left index finger and thumb while a quick running overhand suture of the slit thus formed is made.

REPORT ON THE TREATMENT OF FOURTEEN CASES OF DISEASE OF THE SPINAL CORD, BY THE METHOD OF SUSPENSION.[1]

BY DAVID D. STEWART, M.D.,

LECTURER ON THE DISEASES OF THE SPINAL CORD AND CHIEF OF THE MEDICAL CLINIC IN THE JEFFERSON MEDICAL COLLEGE; PHYSICIAN TO ST. CHRISTOPHER'S HOSPITAL FOR CHILDREN.

ALTHOUGH the treatment of locomotor ataxia by suspension was introduced in 1883, by Motchoukowsky, of Odessa, in Russia, the method received no extended trial in that country, and failed to attract notice elsewhere until the attention of Prof. Charcot was directed to it last autumn. Since the date[2] of the publication of the latter's first lecture on the subject, the method has received such publicity through the journals that a description of it here is unnecessary.[3]

In cord affections occurring secondarily to disease of the vertebræ this method was advocated, and practised with good results, so long ago as 1826 by Prof. J. K. Mitchell, of the Jefferson Medical College, and has been employed for a number of years by Dr. S. Weir Mitchell[4] in the same class of cases. The latter, indeed, about the time of Motchoukowsky's discovery, was induced to attempt suspension in two cases of spastic paraplegia in which no spinal caries existed; the excellent results obtained from it in pressure paralysis having led him to believe that stretching the cord, and thus altering its vascular conditions, even when signs of meningeal inflammation were absent, would helpfully affect both cord and membranes. Unfortunately, in these cases, no benefit followed; had it been otherwise, suspension would, no doubt, long since have been generally recognized as a useful adjunct to our scanty therapy in chronic degenerations of the spinal cord.

Closely following the introduction of the method into France it has been used in many forms of dis-

ease of the cord, in various forms of chronic degeneration of the nervous system, and in functional nervous trouble, such as neurasthenia; but, thus far, no report has appeared of a sufficiently extended trial in these to justify positive conclusions as to its utility. I have not, as yet, suspended more than a few times, at very irregular intervals, cases other than those of cord disease. Efforts are now being made to induce a considerable number of chronic nervous cases, which have been intermittently under observation in the out-patient medical department of the Jefferson Hospital for some time, and which, seemingly, are such as might receive benefit from this treatment, to submit to its trial. Later, a report will be made on suspension in these. The fourteen upon which this paper is based comprise eight tabetics, three cases of spastic paralysis, two of ataxic paraplegia, and one of myelitis. The following are brief histories of these:

CASE I. *Locomotor ataxia; second stage.*—Clement N., aged thirty-eight years; waiter. First seen January 23, 1889. He then had had severe lightning pains for a year or more. There had been present from about the same time incoördination of movement, especially in the dark. This was increasing. There was heightened sexual desire, with nocturnal losses, constipation, and vesical incontinence. Swaying was so decided, with feet together and eyes closed, that he would fall if unsupported. He had lost twenty pounds in weight in eight months. The upper extremities were not involved. There were no eye symptoms. There were plantar anæsthesia, with delay in transmission of an impression, perverted temperature sense, and absent knee-jerk. Had syphilis in 1879.

He was placed on mercuric iodide until treatment by suspension was begun, on February 18th. The only change in his condition then was slight diminution in the severity of the pains. He has been suspended, in all, thirty-six times, usually four times a week, Monday, Wednesday, Thursday, and Saturday being the days chosen. The duration of the first suspension was one minute, the second one and a half minutes, the third two and a half minutes, the fourth three minutes; all the subsequent suspensions were from four to five minutes, usually the latter. He was swung entirely from the ground in all the suspensions. The first three suspensions were by the head alone, but so much spinal pain was felt during them that, thereafter, shoulder-straps were also used, he being directed to raise and lower the arms slowly three to four times in a minute. At the fifth suspension marked improvement was apparent; his gait was decidedly better; static ataxia had lessened materially, the lightning pains had decreased in severity and frequency, and plantar anæsthesia had diminished.

During the second week of treatment the pains entirely disappeared, and have not returned. Since then improvement has been gradual, though continuous, to the present. The increased sexual desire, constipation, and vesical incontinence have disappeared. He is now able to walk with eyes closed; static ataxia is slight; subjective sensation in the plantar surfaces is good, and the two points of the æsthesiometer are now felt at the normal distance; temperature sense is normal; the knee-jerk has not returned.

CASE II. *Locomotor ataxia; second stage.*—William E. T., aged forty-six; clerk. Had been under observation but a short time when suspension was begun. The following is an abstract of the symptoms noted the day of the first suspension: He had *petit mal* for one and a half years preceding the onset of tabetic symptoms three years ago. There then appeared lightning pains, which continued intermittently until suspension was begun. Before the first suspension they were very severe, and were aggravated in damp weather. Sexual desire was at first increased and then lost. There were constipation, alternating with fecal incontinence, and loss of vesical control. The gait is ataxic; there is staggering in the dark and in turning. Swaying is decided with feet together and eyes closed. The upper extremities are unaffected. There is decided tactile anæsthesia of the lower limbs. Temperature sense is perverted. Tactile and temperature sense are decidedly delayed. Knee-jerk is absent. There are no eye symptoms. He is melancholic; attributes his disease to mental worry. No specific history.

He was first suspended February 15th, and subsequently three to four times weekly to the present; but occasionally there was an interval of several days between. The first four suspensions were entirely by the head; in the later ones shoulder-straps were used, the arms being raised and lowered as in the other cases. First suspension occupied three-quarters of a minute; the second two minutes; the third and fourth two and a half minutes, and all the subsequent ones two to five minutes, the average being three minutes. He was rarely suspended five minutes, because of severe pain always appearing in the cervical and dorsal region when the treatment was prolonged. He thinks the improvement better when the time of suspension is shorter. After the fourth suspension there was improvement in the gait, and decided diminution in the severity of the lightning pains, though the weather was bad for some time. After the seventeenth suspension, vesical and fecal incontinence entirely ceased, and has not returned. The improvement in his gait had then begun to be remarked upon by all his acquaintances.

He has now been suspended thirty-two times. There has been no change in his condition since the twenty-fifth suspension. It was then noted that his walk and station were far less ataxic than at first. There is a most decided improvement in his mental condition; cheerfulness has replaced despondence; he has gained strength; appetite and sleep are better than at first. The lightning pains no longer occur; rheumatoid pains are occasionally felt prior to a storm, but are of no severity. Sexual desire and capacity have not returned. Knee-jerk remains absent. There is less tactile anæsthesia in the lower limbs; sensation, however, is still delayed. He can distinguish heat and cold, but there is delay in transmission as before.

CASE III. *Locomotor ataxia; second stage.*—John Van S., aged fifty-three. Has been under observation for ten years. Knee-jerk has not been present during that time. Gait has been ataxic for twenty years; anæsthesia and lancinating pains have been present for the same period. There was loss of sexual power and desire, which returned somewhat for a time, with, also, some amelioration in the other symptoms, under the salts of silver and potassium iodide; but, prior to the first suspension, locomotion without two canes had been impossible for seven years. The gait was typically ataxic, and there was retroflexion of the knee-joints. Lightning pains were severe and constant. Tactile sense was diminished; temperature sense was normal. There was concentric limitation of the visual field with a normal fundus.

The first suspension (one-half minute) was on February 20th; the second (two minutes) on February 25th; the third (two minutes) on the 27th. Since then he has been suspended from three to four times weekly, receiving in all thirty suspensions, which, after the fourth, were of five minutes' duration. No pains occurred during them. The method was the same as in the preceding cases. The lancinating pains disappeared the day following the third suspension, and have not returned. On the day of the fourth suspension (twelfth of treatment) he appeared at the hospital without a cane, coming a distance of several miles, and walking a fair part of the way; the first time he had done without support in locomotion in seven years. Subjective sensation in the plantar surfaces was also better, and he expressed himself as feeling "like an old buck." This improvement in gait has been continuous to the present, and is remarked in wonder by his family and neighbors. Sexual power and tactile sense have improved. The knee-jerk has not returned.

CASE IV.[1] *Locomotor ataxia; second stage.*—George L., aged sixty-three years; schoolmaster. Seven years ago lightning pains, anæsthesia of the lower limbs, and an ataxic gait appeared, with loss of sexual desire. An examination immediately before suspension was begun showed markedly ataxic walk and station; absent knee-jerk; decided tactile anæsthesia in the extremities; Argyll-Robertson pupil. There were girdle and shooting pains. No specific history. He was at first suspended every day for three weeks; and subsequently on alternate days. The average length of each suspension was two and three-quarters minutes. There has been a very distinct improvement in gait, and incoördination is slight compared with what it was. The girdle sensation has disappeared, and the lancinating pains, though not entirely gone, have much ameliorated. The knee-jerk has not returned, and the reflex immobility of the pupils and loss of sexual desire continue. The mental condition has improved.

CASE V. *Locomotor ataxia; first stage.*—James L. E., aged forty; brakeman. For several years he has had characteristic lightning pains, and recently has noticed uncertainty of walk in the dark. With closed eyes there is bad station. The gait is not ataxic. The knee-jerk is absent; no reinforcement. There is Argyll-Robertson pupil. He has been suspended four times. After the second suspension there was a decided lessening in the severity of the pains. This case came to the hospital from a distance, unprepared to remain longer than a week. A report on his condition will be made at another time, after further suspensions.

CASE VI. *Locomotor ataxia; second stage.*—Mrs. M. C., aged forty-eight; general housework. Since September, 1883, she has had paralysis of the left third nerve, causing mydriasis, external strabismus, and almost complete ptosis. In 1887, locomotion became difficult, at first only in the dark, but soon in the light. She has had lightning pains for over a year, and rheumatoid pains occur in the joints, worse in damp weather. There is a constant sensation of burning and weight in the dorso-lumbar region, and the spinous processes of the vertebræ in this situation are decidedly tender on firm pressure. There are: staggering gait; inability to stand with feet together and eyes open; absent knee-jerk; pronounced tactile anæsthesia in the lower limbs, and especially in the plantar surfaces; normal temperature sense. An examination of the eye showed hypermetropia; a normal fundus; total paralysis of the left third nerve; pupils irregular in outline, responding sluggishly to light, and immobile to accommodation. The above points were noted when she first came under observation, two months before beginning suspension, and again immediately before. She had received no benefit from medical treatment.

The first suspension was on February 15th, and the last on March 30th, she receiving it in all twenty-one times, usually four times a week. The first two suspensions occupied three-quarters of a minute; the third, one minute; the subsequent ones from two to five minutes, usually the latter. The method was similar to that pursued in Case I., and the intervals were the same. The first three suspensions were accompanied and succeeded by an increase in the sensations of burning and weight in the dorso-lumbar region; this, later, disappeared, but returned occasionally while suspension was continued. The tenderness over the spinous processes, however, entirely disappeared. The shooting pains were decidedly ameliorated, and station improved after the sixth suspension. The ptosis was noted to be much less at the date of the twelfth suspension. Other than these there were no changes. Loss of knee-jerk, tactile sensation, and sexual desire persisted. After a six weeks' trial she ceased to return for suspension.

CASE VII. *Locomotor ataxia; second stage.*—Mrs. R. C., aged forty-nine; housewife. The following points were noted shortly prior to beginning suspension. Has had characteristic lightning-like pains for fifteen years, and for the past six years an ataxic gait; sensations of numbness from the waist downward; a girdle pain, and absent sexual desire. There were present very bad station; absent knee-jerk; decided tactile anæsthesia in the lower extremities, but normal temperature sense. There were Argyll-Robertson pupil and beginning atrophy

[1] Patient of Dr. E. P. Hershey's.

of the left optic nerve. Because of being light in weight, she was suspended by the head alone.

The duration of each suspension varied between three-quarters of a minute to four minutes. She was suspended in all ten times. At the visit for the fifth suspension it was noted that her gait and station had decidedly improved; she felt stronger physically, was in better spirits, and had little or no pain. After the sixth suspension the ataxia had lessened so considerably that she presented herself for the seventh suspension (the thirteenth day) walking entirely without support—for the first time in several years. The improvement in gait and station and the lessening in the pains were maintained; but at the date of the ninth suspension there was no return of knee-jerk, and tactile and sexual anæsthesia remained. The eye symptoms were unchanged. She complained of having trouble at home, and of being much overworked, and did not return for treatment after the tenth suspension—why, I am unaware, as she stated at the last visit that she was much gratified with the improvement.

CASE VIII. *Locomotor ataxia; second stage.*—Mrs. K. M., aged forty-five years; housework. The following symptoms were noted just prior to beginning suspension. Has had generalized neuralgiform pains for twelve years, with occasional lightning-like pains down the thighs. Has been somewhat ataxic for a number of years. There are decided static ataxia, absent knee-jerk, paræsthesiæ in the lower limbs, diminished and delayed tactile and temperature sense in the plantar surfaces, absent sexual desire, Argyll-Robertson pupil. She was suspended in all eight times, and then was forced to discontinue her visits because of contracting a severe cold. At the time of the last suspension the only improvement noticeable was in the ataxia. The walk was normal and there was far better station.

CASE IX. *Primary spastic paraplegia.*—Henry S. A., aged thirty-seven years; cake-baker. Eleven years ago there gradually appeared weakness in the lower limbs, with rigidity and tremors. For several years has been totally unable to walk without crutches. Immediately prior to beginning suspension it was noted that he could not walk more than a few steps with them. The gait was typically spastic and the limbs shook as he progressed from the clonus produced as the ball of each foot rested alternately on the floor. The lower limbs were rigid; the knee-jerk was much heightened, ankle clonus was very decided, and there was a general increase in the tendon and periosteal reactions. Sensation was normal; coördination, also, as far as it could be tested. There had been obstinate constipation for years, and, occasionally, rheumatoid arthritic pains.[1] No specific history.

Suspension was begun on February 25th and continued four times weekly until March 25th, when he returned to his home in Camden. Though compelled to depart, he was so unwilling to abandon a treatment which seemed to be productive of so much good that he purchased an apparatus and has suspended himself daily from March 26th.[1] Allowing for psychical effect—for he has become a decided enthusiast on the method—the improvement in his condition has been marked. The day following the second suspension he stated the limbs felt less stiff, their movements were freer and more under control, and that locomotion with the aid of crutches was less difficult; this at the time of the fourth suspension, was apparent to myself and others who then saw him. There were less spasm and rigidity and the gait had improved. Coldness of the feet had been constantly present before suspension was begun, but disappeared after the first hanging, and has not returned. He recently wrote to me, in reply to an inquiry as to his condition, that he had discarded his crutches and now goes about the house readily enough with the aid of two canes; that he stands without fear of falling, and that there is freer movement in the feet and less tremor and spasm in the limbs than there has been for ten years.

CASE X. *Primary spastic paraplegia.*—Geo. F., aged thirty-eight years; shop-keeper. Five years ago the lower limbs became gradually weak, easily fatigued, and were the seat of stiffness and occasional spasm. A typical spastic condition is present. The walk is spasmodic, the knee-jerk much exaggerated, and there is a decided ankle clonus. There are no disturbances of sensation or coördination. The pupils are normal. There is beginning atrophy of the right optic nerve. He had syphilis seventeen years ago. He has been suspended thirty-four times; method, duration, and intervals, the same as in Case I. There has been no decided improvement in his condition. After the seventh suspension he stated he had begun to feel in higher spirits and ate and slept better. He thought the limbs were not so weak and rigid as formerly. I, however, noticed no difference then, but, on examining him the day of the tenth suspension, there seemed less spasticity and his walk had improved, but the tendon reflexes continued exaggerated as before. Since then the improvement in gait has not been marked. There is now, however, much less fatigue felt in the legs than formerly and less tendency to spasm. The knee-jerk continues heightened, but the foot clonus is less easily elicited and is feebler.

CASE XI. *Primary spastic paraplegia.*—Samuel G., aged fifty-three years. A year ago there gradually developed weakness and heaviness in the legs and a tendency to jerking of the muscles. Several attacks of colic preceded the appearance of these symptoms. There is weakness in the legs on slight exertion and the gait is slightly spastic; the knee-jerk is increased and a clonus can be produced in the left ankle. Tactile sensation and coördination are unimpaired. There are no electrical changes and no specific history. There is atrophy of the left optic nerve. He was suspended thirty-four times; the method, duration, intervals, etc., were the same as in Case I. There has been no improvement in his condition, save that he has lost a feeling

[1] It is interesting to note that, when he first presented himself for treatment, one and a half years ago, and was under observation one week in the wards, his occupation and the eliciting of the last mentioned symptoms, caused me to suspect lead poisoning. His urine was then examined by Prof. Leffmann, who reported that it contained considerable lead.

[1] He has now had forty-five suspensions.

of nervousness and dread that was very prominent before suspension was begun. This disappeared in the second week.

CASE XII. *Combined lateral and posterior sclerosis.*—Henry S., aged forty years; shuttlemaker. He visited the clinic once, five years ago, in search of a diagnosis. The following points, with others, in his history, were then noticed: Staggering gait; left knee-jerk much increased; incoördination; cannot walk or stand without assistance; impaired grasp, both hands; shooting pains in the extremities; pruritus; constipation; incontinence of urine; normal tactile sense; double optic neuritis; loss of color sense; peripheral vision better than central; no specific history. He was recently invited to present himself for suspension. Additional points noted at the date of the first suspension are, that the first symptoms appeared ten years ago, and were those of combined lateral and posterior sclerosis. There is now present a spastic gait; inability to walk or stand unsupported; rigid limbs; much exaggerated knee-jerk; very decided ankle clonus; pronounced incoördination in both upper and lower extremities; normal tactile and temperature sense; unimpaired sexual power; chest pains; constipation; no bladder difficulty; advanced double optic atrophy and limitation of the visual field; pupils normal in size, and immobile. He received nine suspensions. At the time of the third suspension he felt decidedly stronger and better; limbs were more supple; had walked more in the two preceding days than for three or four years. The fourth and fifth suspensions caused severe pain in the back and limbs, and slight faintness. After the ninth suspension he abandoned the treatment, believing that the distance he was compelled to travel to be suspended overcame any benefit he received.

CASE XIII. *Combined lateral and posterior sclerosis.*—John S., aged thirty-one years; miner. Has had lightning-like pains in the extremities, more or less constantly, for three and a half years, and dull aching in the lumbar and sacral region. Motor weakness and incoördination in the legs, with stiffness and tremors, appeared shortly after the onset of the pains, and are increasing. He is unable to walk with closed eyes. The gait is slightly spastic. The leg muscles have dwindled. There is slight plantar anæsthesia and delay in the transmission of a tactile impression. The knee-jerk is very active; ankle clonus is pronounced. The arms are normal. There is no bladder or rectal trouble. Sexual power impaired. No specific history. He believes the disease was induced by constant exposure to wet cold. He was suspended six times, and then returned home. Subsequently, without my knowledge, he used suspension on alternate days for six weeks, and he now writes that he has but slight pains and that locomotion is "almost as good as ever."

CASE XIV. *Subacute dorso-lumbar meningo-myelitis.*—John B., aged twenty-nine; miner. In March, 1888, five weeks after a fall upon the buttocks, in which he felt himself much shaken, there appeared difficulty in locomotion; lancinating pains in the course of the ilio-hypogastric and ilio-inguinal nerves, and in the thighs, which continued constantly for several months. The pains were of great severity, and necessitated the frequent hypodermatic use of morphine for their relief. In August, the loss of power became absolute; he was then unable to walk, even with crutches. I saw him first on February 28, 1889, when he was brought to the hospital for treatment. There was then total paraplegia. He could not maintain the erect posture, though held by two men. The legs and thighs were somewhat wasted; a spastic condition was developing, and reaction of degeneration had appeared in the anterior thigh muscles. The spinous processes of the first and second lumbar vertebræ were decidedly tender on pressure, and the vertebral points below this were slightly so. There was marked diminution in tactile perception in the lower limbs; the two points of the æsthesiometer being felt as one at their greatest separation. Heat and cold applied to the plantar surfaces seemed equally hot, and the touch of a feather produced a burning sensation. A very faint plantar reflex was present, but no gluteal or cremasteric. Knee-jerk was just perceptible on the right; a trifle better on the left, but much enfeebled. A hot sponge drawn down the spine showed a hyperæsthetic zone in the lower dorsal region.

Suspension was begun on February 28th. The neck and shoulder straps were used. He was always drawn entirely from the floor, and the arms were raised and lowered at intervals, as in the other cases. The first suspension occupied one minute; the second three minutes; the fourth four and a half minutes; all the subsequent ones five minutes. He has now received thirty-one suspensions, and the improvement in the paraplegia has been remarkable. After the second suspension he was able to stand with crutches, and, at the time of the fourth, he got about the wards with their help, and, since April 1st (eighteen suspensions), he has been able to walk a short distance with the aid of one cane. The rigid condition of the limbs has lessened, and their nutrition is better. The tenderness over the lumbar vertebræ had entirely disappeared by the latter part of March. Pains occasionally appear in the interval of the suspensions in the course of the ilio-inguinal and ilio-hypogastric nerves, but are always dispersed by a suspension. The knee-jerks are somewhat more active than normal. The plantar reflex has improved; the gluteal and cremasteric remain absent. Anæsthesia in the plantar surfaces has lessened very materially.

The total number of suspensions made in these cases is upwards of 352. An extended analysis of the results obtained is unnecessary. It may be seen by a glance at the histories that, in the tabetics, the symptoms which were first and most strikingly relieved were the ataxia and the lancinating pains; improvement in these occurred in all,[1] and after a very few suspensions; and that, if any relation existed between the early appearance and extent of

[1] No pains were present in Case VIII. while under treatment by suspension.

the improvement and the duration of the disease, it is a direct one; the more chronic cases being those most promptly and decidedly benefited. The improvement in these two symptoms, the most prominent and distressing of the disease, in at least two of the cases (III. and VII.) was so prompt and decided that it may well be considered truly remarkable.

Bladder and rectal difficulty, present in two of the tabetics, and increased sexual desire present in one, have disappeared. Diminution in, or loss of, sexual desire, present in five, has improved in but one. Tactile anæsthesia has much improved in three and slightly in one; not at all in four. A somewhat melancholic condition, present in five of the tabetics, disappeared after a few suspensions. This was not due directly to the suspensions, but was rather secondary to the lessening of the pains and ataxia. In none of the eight has the knee-jerk returned, even with reinforcement.

In the three spastic cases, diminution in the paralysis, rigidity, and spasm has been striking in one and slight in another; in the third, no change has occurred in these symptoms.

In one of the ataxic paraplegic cases ataxia and paralysis seemed to be lessened after the second suspension. Unfortunately, this improvement was not maintained, possibly because suspension was not persevered in. The other case writes me that there has been marked improvement in gait and pains.

In the case of myelitis, the improvement in the paraplegia and in the general condition has been decided.

Eye symptoms, where present in the fourteen, have undergone no change.

As these cases are few in number, and have been under treatment by suspension but a comparatively short time, no very definite deductions can yet be drawn as to the exact value of this method in the treatment of degenerative and inflammatory diseases of the cord. It may, however, be safely asserted, from the favorable results obtained in nearly all of the tabetic cases, that suspension is of great service in locomotor ataxia, but, whether palliative merely or actually curative, the time has not arrived for definite reply. It is certainly of use in lateral sclerosis; and, in myelitis, the decided improvement produced in one case, in which absolute paraplegia had existed for over six months, commends its trial in others. That suspension will, even though aided by wisely directed medical and hygienic means, effect a cure in degenerative disease of the cord is, I think, doubtful; but, as an adjunct to other modes of treatment, its utility is beyond question.

The recent plausible explanation as to the action of suspension in tabes, offered by Althaus,[1] indicates that permanent benefit may result from this method, provided that the further progress of the disease can be arrested by other means, and that it has not advanced to complete destruction of the nerve tubules; and that, even where its advance cannot be thus stayed, temporary good may still be accomplished by suspension. Althaus's ingenious explanation applies equally to other degenerative diseases of the cord than tabes, and if it is true of the chronic degenerations, in which the pathological changes originate in the nerve elements and the overgrowth of connective tissue is secondary, it is, theoretically, far more so of inflammatory processes which, starting in the connective tissue, cause, primarily, at least, far less damage to the nerve tubules In chronic inflammations of the cord or its investing membranes which are stationary and are encountered before the contracting perineural tissue has, by compression, done more than interfere with the nutrition and conductivity of the fibres, not irreparably damaging their structure, the effect of suspension should be curative; for, by stretching the cord and the thickened and adherent membranes, the inflammatory tissue pressing upon the axis-cylinders will be loosened and broken down, setting free the latter and permitting them to resume their functions.

TWENTY CONSECUTIVE CASES OF ABDOMINAL SECTION, WITH ONE DEATH.[1]

BY J. M. BALDY, M.D.,
OF PHILADELPHIA

THIS paper embraces the report of twenty abdominal sections taken from the surgical experience of the writer, and are reported simply as a basis for some general remarks on this class of surgery. The cases are taken consecutively, and include the only death I have as yet met with. No case has been refused for operation where there seemed a possible chance for life, and several of them were in such a condition that this chance seemed very small indeed. The general mortality is fully as low as that obtained by Lawson Tait, as reported in his last one thousand cases. Of the operations themselves I have little to say. They have been neither harder nor easier than those of a similar character done by other operators. The fact becomes daily more and more apparent to me, that all abdominal operations, with complications, are difficult; in fact, each new one seems more difficult and delicate than the last. It is impossible to lay down any definite rule of procedure in any class of cases, for the reason that no two are alike; it is simply surprising to find how differently even two apparently similar cases will result. At

[1] Read before the Philadelphia County Medical Society, May 22, 1889.

times one has need of all his courage and skill, to meet the requirements and complications of the case.

Seventeen of the list were complicated by adhesions, more or less dense, and the difficulty, nay, almost impossibility at times of breaking these adhesions, have convinced me of the folly of even attempting to cure such cases by either electricity or massage. In some cases, the electricity would have destroyed the surrounding tissues much sooner than it would have even made an impression on the adhesions themselves, so extensive, dense, and organized were they. It is simple unadulterated nonsense to tell me that I could have done with safety, through the thickness of the tissues of the abdominal wall and vagina, that which I was barely able to do with my fingers directly on the disease, and the patient fully anæsthetized; and massage, if carried to the extent advocated by some of its votaries, loses even the merit of being harmless, but becomes extremely dangerous. If the patients of the gentlemen who use this remedy (or say they do) will submit to the pain necessarily incident to this treatment, they must be dealing with a much less serious type of cases than it has been my fortune to handle.

In eleven of these cases I have used the drainage tube; nor in any case have I ever regretted its use. On several other occasions I should have used it, but that the after-treatment was conducted by another than myself, the patient residing in the country. In one case the tube was accidentally displaced by the patient, before she was completely from under the influence of the anæsthetic. In this case the adhesions and hemorrhage had been particularly severe, and I was considerably worried over its loss for several days; the convalescence progressed, however, with out any incident worthy of note. I have since then several times done without a tube and depended on purgatives for drainage, with a greater ease of mind, especially in the out-of-town cases. Irrigation with boiled distilled water, and when that has become exhausted, simple boiled water, has been a constant resource and of the utmost benefit. There is absolutely nothing which will take its place for cleaning the abdominal cavity of clots and débris, as well as for its stimulating effect upon the patient. Of late, however, two surgeons have expressed the opinion that the flushing is decidedly dangerous, and base that opinion, each upon one case. Both the patients died after the operation in which warm-water irrigation had been used. The rest of the profession seem to be unanimous in the opinion that irrigation is safe and beneficial.

In the fatal case of M. Polaillon, a French surgeon:

"The patient *took chloroform badly*, the excited stage was long and she readily came to, though plenty of chloroform, out of a new bottle, was administered on a piece of lint. He employed distilled water, previously boiled, and containing one part of *carbolic acid* to a hundred.

"During the flushing, respiration became rapid, then grew feeble and ceased; the face became blue. The heart continued to beat regularly. The alarming symptoms began at a quarter past ten o'clock. Artificial respiration was continued till eleven. Then a few feeble respirations began, and continued for a quarter of an hour; the pupils were then half contracted. The heart beat regularly and quickly. The patient continued unconscious. In spite of stimulants, spontaneous respiration could not be permanently maintained. Phlebotomy resulted in the escape of a few drops of very dark blood from the left arm. Gradually the heart's action became more and more feeble, the face grew pale, flatus escaped from the anus, and the pupils dilated. She was thirty-five minutes under chloroform, and about an ounce and a half of the anæsthetic had been used."

Of course, the case died of the chloroform; the history is too complete to admit of any other interpretation, nor do I think for a moment that any one but the operator could think otherwise.

The second case was a patient of Dr. Weir, of New York. Of this case, Dr. Jacobus says:

"How the death of this patient can be, even indirectly, attributed to hot douching, I cannot understand, for it was a case of recurring appendicitis, with several perforations, general peritonitis and partial collapse, operated upon on the fifth day, after having been treated by other physicians, then removed to a hospital and examined under ether, the day previous to the operation."

This is the flimsy evidence on which the objection to irrigation is founded. If surgeons will overdose their patients with chloroform or wait until the eleventh hour to operate, they must expect them to die. I have repeatedly flushed the abdomen to the diaphragm and have yet to see anything but good results. My observations and inquiries amongst my friends have disclosed the same experience without an exception.

A number of these cases were confined to bed with a peritonitis at the time of the operation. All sorts of complications have been met with. In three cases the vermiform appendix had to be freed and then removed on account of its diseased condition. In one, when torn loose, it was found perforated in two places; the appendix was simply ligated and cut away. In none of these cases did any unpleasant symptom arise from this procedure.

The patients have for the most part been operated on at their own homes and in several instances were nursed by their friends. This has, of course, necessitated an enormous amount of extra work for myself; but otherwise they would not have been operated on, having absolutely refused to go to a hospital. The result only helps to emphasize the fact that hospitals are more luxuries than necessities for these operations, notwithstanding the opinion of some operators to the contrary.

In two of these cases there have resulted ventral hernias. In three fistula tracks have followed. A

ligature has recently come away from one of these fistulas and it will now probably close. The other two fistula tracks both followed supra-vaginal hysterectomies.

The after-treatment has been practically, in many cases, nothing. Unless special indications arise they recover without having had a single dose of medicine, excepting sulphate of magnesium, which is generally given on the third day. Until the third day they get nothing to eat. Solid food is given by the fourth or fifth day, if they wish it. If thirst is great, it is relieved by rectal injections, at intervals, of about half a pint of warm water; otherwise tablespoonfuls of soda water are depended on. Opium I have never used and never expect to.

The simpler the details of the operation the better. In ordinary cases my whole armamentarium consists of two ligature needles, two or three suture needles, a knife, a pair of scissors, a sponge-holder, half a dozen hæmostatic forceps, a drainage and an irrigating tube. Pure silk is used both for ligatures and sutures. The dressing consists of a few strips of gauze, a pad of absorbent cotton and a six-tailed bandage. My bag stands near by and contains all other necessary instruments, but it is exceedingly rare that I have to resort to them. The less work done with instruments and the more with the fingers the safer it is for the patient. One often sees operators with six, eight, or even ten pairs of forceps hanging to the sides of the incision. These instruments are not at all desirable and where it is necessary to use them to control hemorrhage, they can safely be removed by the time the peritoneum is opened. It is exceptional that I have a single pair hanging to the vessels when my fingers enter the peritoneal cavity. They crush and bruise the tissues and only tend to prevent good union. In all the details of the preparation for the operation and of the operation itself, the most perfect and rigid attempts at cleanliness have been observed. All instruments, sponges, dressings, etc., used about an operation are prepared by myself, when possible.

It is daily becoming more apparent that inexperienced and untrained men should not be tempted lightly to enter into the abdominal operation. An alarmingly large number of operations have lately come to my notice, by men who have presumably never attempted the procedure before, and who have been assisted by men equally inexperienced and incapable of dealing with possible complications. A considerable number of these cases have, of course, ended fatally—cases which should have all recovered had a skilled operator undertaken them. I do not mean to say that a physician with only a limited experience should never attempt an abdominal operation, because I am very decidedly of the opinion that every surgeon in the land should be prepared in an emergency to open the abdominal cavity and attempt to deal with what he finds. Our country is so large, and the different settlements and towns so wide apart, that it is an impossibility always to obtain skilled assistance; even where it could be obtained there are times when physicians have no moral right to wait long enough for its arrival. If a tubal pregnancy has ruptured and the patient is bleeding to death, that belly should be opened at once, and by the first man with any respectable amount of surgical experience who may first see the patient. Any physician attending a case of labor, perhaps in the country, may meet with a ruptured uterus, and will give his patient a much better chance for life if he open the abdomen immediately. And so it is with many cases of intestinal obstruction, gunshot and stab wounds. A delay of even a few hours in these cases is responsible for their terrible mortality, and it would be better for any one with good general surgical judgment and skill to open the abdomen, than to leave it unopened or even to delay. It is full time that members of the profession had learned the importance of this and realized their own individual responsibility in allowing such patients to die, without an effort to save them.

But excepting as an emergency and life-saving procedure, I am just as decidedly of the opinion that men without special experience should never open the abdominal cavity, both for their patient's sake and for that of their own reputation. If a simple ovarian cyst is found the operation is easy enough and any tyro could finish it successfully; but just as surely as serious complications are met with both the patient and doctor are in trouble.

I may mention some of the more recent cases of which I am cognizant, which will serve to illustrate some of the points.

CASE I.—A young married woman with a good-sized cystic tumor of the abdomen; in good general health; within one hour's ride of Philadelphia. Operation undertaken by several young men, but without even a good knowledge of general surgery. A long time was wasted in obtaining entrance into the peritoneal cavity. The cyst was found adherent and adhesions bled on being freed. Operation lasted over two hours, and finally ended by leaving it only half finished, with part of the cyst *in situ*. Death on the following day.

CASE II.—Young healthy married woman with cystic disease of abdomen. Operator's first case. Cyst adherent. Bleeding profuse, and large hæmostatics plunged blindly into pelvis in hopes of controlling it. Operation over three hours. Death in a few days.

CASE III.—Young healthy married woman. Unruptured tubal pregnancy diagnosed. Patient lived in a town which could have been reached in a short time by an expert. The ambitious attendant put the woman to bed, took several days to prepare for the operation, and together with four friends opened the abdomen. Operation lasted for five hours; not finished; patient bled to death on the table.

This is the only case of tubal pregnancy I have ever known to be killed by an operation. I could relate many more equally as distressing, but these

cases tell all that is necessary and will justify the remarks I have already made.

There are two complications in abdominal surgery constantly met with, and in dealing with which men show their skill and judgment or display their total unfitness for such work: these are adhesions and hemorrhage. They are, moreover, constant companions; where there are adhesions to be dealt with, there is also nearly always, of necessity, bleeding. Adhesions are not things to be blindly torn loose. In dealing with them, the utmost care and judgment must be constantly exercised, and the almost instinctive knowledge of when to break and when to ligate them, must be ever present. Nor are adhesions things to be afraid of. It matters not how dense they are, it is exceptional that they cannot be successfully disposed of. The man who loses his head and becomes frightened because of tight adhesions, had better never attempt this class of surgery, as they are almost sure to be met with in greater or less degree.

A careful survey of the whole field should first be taken by the surgeon, for the most part with his fingers, and a decision carefully arrived at as to whether or not it will be possible and safe to remove the disease. The decision once made in the affirmative and the enucleation once begun, it should never, but under very exceptional circumstances, be stopped. The worse results obtained in abdominal surgery are in these unfinished operations. The great danger of this half work was sounded some years ago by Lawson Tait, and is to-day accepted as sound teaching by all who have a right to an opinion on the subject. There is constant danger attending the breaking up of adhesions. One may at any time open an intestine and have the question of a resection to decide; a ureter may be torn out at any moment and a nephrectomy must of

No.	Pathological condition or symptoms.	Drainage.	Adhesions.	Result.	Effect of operation.	Remarks.
1	Pelvic inflammatory disease; ovarian cyst.	No.	Dense and universal.	Recovery.	Great relief from symptoms.	Adhesions so great that it was impossible to reach pelvis; nothing removed. Ventral hernia.
2	Constant local pain; convulsions during menstruation; impossible coition from pain; chronic salpingitis; small cirrhotic ovaries.	No.	Yes.	Recovery.	Only gradual relief; not yet complete; convulsions seldom; coition possible and easy.	From being a chronic almost bedridden invalid, is now able to attend to her household and marital duties.
3	Left puerperal pyosalpinx.	Yes.	Dense and universal	Recovery.	Cure.	First case of the kind ever operated on in which life was saved.
4	Pyosalpinx.	Yes.	Universal and dense	Recovery.	Cure.	Three weeks in bed with peritonitis; disease seven years' standing.
5	Cirrhotic ovaries, prolapsed and adherent.	No.	Yes.	Recovery.	Cure.	Relief gradual but complete; convulsive attacks, which were cured.
6	Ovarian cyst; retro-peritoneal cyst; enlarged cirrhotic ovary.	No.	Yes.	Recovery.	Pelvic abscess.	Fourth day walked to kitchen and ate her dinner, sitting at table; out of bed frequently.
7	Pelvic abscess.	Yes.	Yes.	Recovery.	Cure.	Ventral hernia.
8	Fibroid uterus; enormous distention from ascites; hysterectomy, extra-peritoneal.	Yes.	No.	Recovery.	Cure.	Fistula track; ventral hernia; had been tapped eight times.
9	Ovarian cyst; ventral hernia.	No.	No.	Recovery.	Purulent peritonitis.	
10	Purulent peritonitis.	Yes.	Yes.	Death.	.....	Same as Case 9. Lived six days. An earlier operation would have saved her.
11	Double pyosalpinx.	Yes.	Dense and universal.	Recovery.	Cure.	Almost died of hemorrhage on the table.
12	Right pyosalpinx and ovarian abscess; left hæmatocele.	Yes.	Universal.	Recovery.	Cure	Peritonitis at time of operation.
13	Prolapsed and adherent ovaries, four times natural size.	No.	Yes.	Recovery.	Cure.	For a few months complete cure; lately some pain, probably from adhesions.
14	Fibro-cystic uterus; supra vaginal hysterectomy.	Yes.	No.	Recovery.	Cure.	Fistula track; had been diagnosed and treated for hernia.
15	Extra-uterine pregnancy.	Yes.	Universal.	Recovery.	Abscess.	Of a month's rupture and commencing gangrene.
16	Multiple abscesses.	Yes.	Yes.	Recovery.	Cure.	Fistula track; ligature recently came away, and track will probably close
17	Left ovarian cyst; right pyosalpinx and ovarian abscess.	Yes.	Universal but light.	Recovery.	Cure.	Had severe attack of peritonitis during convalescence.
18	Right ovarian cyst; left cirrhotic ovary	No.	Yes.	Recovery.	Cure.	Peritonitis at time of operation.
19	Ovaries greatly enlarged, prolapsed, adherent, and painful.	No.	Yes.	Recovery.	Cure.	Inversion of uterus had been reduced, but constantly tended to re-invert; operation to correct this tendency.
20	Pyosalpinx and chronic salpingitis.	No.	Yes.	Recovery.	Cure.	Right tube adherent to uterus from over fundus to vaginal vault.

necessity follow. I have known of the whole circumference of the sigmoid flexure of the bowel being torn away and a closure of the two ends of the gut necessitated; often the coats of the intestine are torn away down to the mucous lining, and a perforation may occur some days subsequently. The bladder has been opened a great number of times. With these dangers ahead, it can readily be seen why untrained men should keep their hands off, unless absolutely necessary.

In addition to all this, bleeding is constant, as I have said, and may be of two kinds, either venous or arterial. Fortunately, the vast majority of it is simply venous or a general oozing. Where an artery of any size is torn, is must be at once secured and ligated, but otherwise the bleeding had better be left alone or controlled by skilful handling of sponges; it will not be often that this cannot be done. But whether controlled in this manner or not, there is no time to be wasted over it. The very best chance of stopping it is to finish the enucleation quickly and apply the ligature to the pedicle, then there is time and room enough to deal with what may be left, which does not often amount to much. It has lately been proposed and found necessary to throw a ligature around the uterine artery on each side, by passing a threaded needle deep through the sides of the uterus and thus include the artery. I have never seen a case where I even had to think of this procedure, and I have seen some very free bleeding; surely it would take very rough and careless handling often to necessitate a resort to it. However, an uncontrollable case may at times occur, and it is a point well worth bearing in mind. Often the mere bringing together of torn peritoneal edges over a denuded and bleeding surface is sufficient to control an otherwise troublesome point. Much of it may safely be left to the drainage tube. I never like to use styptics when it can be avoided. It is the premature attempt to control bleeding which is often so disastrous. Men find a pretty free flow of blood, and, not being accustomed to it, become frightened and stop everything in the endeavor to control it. This they find oftentimes impossible; the indication then is to finish quickly and stop the bleeding at its root. The pedicle ligature will stop it all, or what is still left is not alarming. Had such been the course pursued in the tubal pregnancy case mentioned, the operation would most probably have been finished and the patient survived. The one redeeming feature of that case is, that the same men and their friends will never be tempted into another such operation; but, unfortunately, the woman's friends and acquaintances will also never be tempted into one. And so indirectly that one case will probably be responsible for the death of half a dozen or more others, who might be saved did they not refuse assistance.

Abdominal surgery, of necessity, has enough legitimate deaths to answer for, without being loaded down by such unnecessary and frightful examples.

Note.—Since the above was written I have had a patient die of apoplexy, on the seventeenth day after operation. The case was one of intra-ligamentous papillomatous cyst. Second operation. Had done well from the first. Small quantity of pus from tube. Tube had been perfectly dry and clean for some days, pulse and temperature normal. Said she never felt better in her life. Had slept soundly all night, ate a good breakfast and was talking and joking with nurse when she suddenly had a convulsion; became unconscious and died within twenty minutes. Post-mortem revealed a calcareous condition of the mitral valves of the heart. At the bifurcation of two vessels in the fourth ventricle, a piece of the calcareous plate was found lodged, one of the vessels was ruptured and the ventricle half full of blood-clot. Everything else in the body was healthy. A full report of the case will be shortly published. Of course, I do not consider this a death from operation, but have thought it proper to speak of it in connection with this paper.

328 South Seventeenth Street.

MEDICAL PROGRESS.

Excision of the Cæcum.—At the Surgical Congress of Bologna, Prof. Durante related a case in which he had removed the cæcum, an operation which he said had been performed only twice before, namely, by Lawson Tait and Billroth. The patient was a woman aged fifty-six, who for four or five years had suffered from obscure pain in the right iliac fossa when at stool. The pain increased in intensity and became paroxysmal, and the patient almost starved herself with the object of sparing herself the torture of defecation. On examination, a resisting tumor was found in the right iliac fossa, extending downward toward the upper outlet of the pelvis. It was only painful during the passage of feces. Cancer of the cæcum or the neighboring parts was suspected, and the abdomen was opened. The tumor, which was as large as a lemon, was found adherent to the iliac fossa, the parietal peritoneum and coils of the small intestine being matted to it so firmly that the lower end of the latter, measuring 25 centimetres in length, together with the cæcum and a portion of the ascending colon, was removed with it. The two ends of the divided intestine were brought together by three rows of suture, namely, an interrupted one through the mucous coat, a hemstitch one through the serous and muscular coats, and a third through the serous coat. The abdominal wound was stitched up, and the patient rapidly recovered without rise of temperature. On the seventh day she had a motion of the bowels without any trouble, and on the tenth day she got up. She has continued ever since in perfect health. The tumor, which had almost completely blocked up the intestine, was found to be of tubercular nature.

Dr. Trombetta said he had published an almost exactly similar case. There was stenosis of the intestine,

caused apparently by a tumor; he had, therefore, removed the cæcum with the ascending colon and a portion of the small gut, and made an artificial anus. The patient died on the fourteenth day from rupture of the intestine with fecal extravasation. The case proved to be one of typhlitis and perityphlitis, with small abscesses.

DR. BASSINI related a case in which he had removed the cæcum with a portion of the small gut, and from eight to nine centimetres of the ascending colon from a girl aged 22 or 23 for adenoma. Rapid recovery took place.—*The British Med. Journal*, May 4, 1889.

Creolin as an Antiseptic.—Creolin is being actively discussed on the continent at present, as well as in this country. Whether it will stand the test of the rigid examinations to which it is being subjected, remains yet to be seen. The main point of discussion is whether creolin is an antiseptic or not. German authorities seem specially interested, and their opinions are quoted at length in many medical journals.

DR. P. BAUMGARTEN (*Centralbl. f. Bact.*, vol. v., No. 4, 1889) states that he has found it to be a strong animal poison and also an antiseptic, yet only in solutions of a strength that would be fatal to animal life.

DR. BEHRING (*Deutsche militärerztl. Zeitschrift*, 1889, p. 337) comes to the conclusion that creolin possesses antiseptic properties three or four times as weak as those of carbolic acid in solutions of similar strength. A two per cent. solution of creolin will not disinfect wounds. The drug is not so poisonous as carbolic acid.

DR. EISENBERG states that he has found two per cent. to five per cent. solutions of creolin to be powerfully antiseptic; killing almost immediately streptococci, staphylococci, cholera bacilli, and other bacteria. He prophesies a brilliant future for the drug. SEIDEL and HÖRNICKE agree with EISENBERG, and consider ten per cent. creolin gauze or cotton to be an admirable substitute for bichloride gauze. The former preparations may now be purchased in the German market.

HÜNERMANN, as the result of a long series of investigations, states that creolin has no right among antiseptics. It undoubtedly retards and in some cases even prevents the further growth of bacteria, but does not ill them. Koch's experiments have proved that the oil of mustard in weak solutions may hinder the growth of bacteria, yet no one would for a moment regard it in the light of an antiseptic, yet this, he claims, is what is being done with creolin.

DR. KORTÜRN (*Centralbl. f. Gynäk.*, No. 6, 1889) and DR. BUNSEN have tried the drug in obstetrics, and say that they have found it a most admirable antiseptic. They claim that it is not so irritating as carbolic acid, and that it also possesses styptic properties. Kortürn uses wet creolin gauze exclusively for plugging the uterine cavity in cases of severe hemorrhage. For washing the vagina, Bunsen uses only a one-half per cent. solution. He states also that a two per cent. solution immediately kills pediculi pubis.

DR. RAUSCHE (*Deutsche med. Wochenschrift*, April 25, 1889) highly lauds the deodorizing properties of creolin and uses it as an application for burns, superficial wounds, etc. He also advocates its use in the form of creolin soap, for cleansing and deodorizing the hands after operations.

DRS. AMON and PRUTSCHER have used a weak solution of creolin in optic and aural surgery to great advantage.

PURJESZ (*Pester med.-chir. Presse*, No. 11, 1889) treated several cases of suppurative inflammation of the tympanic cavity with creolin with marked success, using five or six drops of pure creolin in a pint of water as a wash. Otitis media was also treated in the same manner with success.

SPÄTH, PIESKOFF, and others, have used it advantageously in diseases of the throat, nose, and larynx, either in the form of powder of varying strengths, or in glycerine, or as a wash in the following formula:

℞.—Creolin	1 part.
Menthol	1 "
Water	500 parts.

Extirpation of the Uterus for Cancer in France.—Views on the treatment of uterine cancer are much divided in this country and Germany. A discussion on the subject has recently taken place at Lyons before the *Société Nationale de Médecine*. DR. DUCHAMP, like Dr. John Williams and unlike most of the German authorities, finds that uterine cancer tends to spread toward the broad ligaments, and not along the endometrium, recurrence after supravaginal amputation of the cervix taking place not in the uterine stump, but in the broad ligament and adjacent connective tissue. This theory is made by the above-named English authority to justify supravaginal amputation in preference to total extirpation.

Dr. Duchamp, of Lyons, on the other hand, begins supravaginal amputation of the cervix as an exploratory operation. In the *Lyon Médical* he states that when the cancerous infiltration has passed beyond the vaginal portion of the cervix, he sets the entire cervix free by dissecting it away from the bladder as high as the level of the utero-vesical pouch, which serous fold, he finds, is "easy to recognize." Then he cuts through the cervix at the same level. When the cut surface appears healthy, he limits the operation to a supravaginal amputation of the cervix. On the contrary, should the wound on the proximal part of the cervix or the cervical canal appear infected, he performs total extirpation of the uterus through the vagina. Dr. Duchamp's four cases, where he extirpated the uterus on the above principles, all recovered from the operation. He admits, however, that in two the broad ligaments were invaded, and the radical procedure was undertaken too late. The first case lived for six months; one ureter had been included in a ligature, ureteric stricture resulted, and the patient died of uræmic convulsions. The three remaining cases were all subjected to operations within five months of the publication of Dr. Duchamp's paper, so no conclusions respecting recurrence can yet be drawn from them.—*The British Med. Journal*, May 4, 1889.

Treatment of Diphtheria.—DR. RENVERS, one of Leyden's assistants, gives the following outline as his usual treatment of diphtheria:

1. Antiseptic washing and disinfection of the mouth and throat every two or three hours. Ice pills may be given, and inhalations are also of value.

2. Little or no medicine need be given internally, and even when high fever exists the use of antipyretics is to be avoided.

3. Complete rest is indispensable to the patient. Constant washing of the mouth and long gargling are only weakening and of little value.

4. Morphine, if used with caution, will be found invaluable. No other drug seems to quiet the patient so quickly and give such refreshing and strengthening sleep. The dose used should always be small, varying from one-twentieth to one-sixth of a grain.

5. The nourishment of the patient is of special importance. If there be any difficulty in swallowing, or if the patient refuses food, artificial feeding should at once be resorted to. The diet should be strong, consisting of half pint of milk, three times a day, together with the yolk of two or three eggs, an ounce of sugar, and about three ounces of sherry wine.—*Münchener med. Wochenschrift*, April 23, 1889.

Salicylate of Mercury in Blennorrhagia.—PROF. SCHWIMMER (*Wien. med. Wochenschr.*, No. 8, 1889) has met with great success in treating blennorrhagia, both acute and chronic, with injections of salicylate of mercury. He suggests the following formulæ:

1. In acute blennorrhagia,

℞.—Dist. water . . . . ℥iijss.
Salicylate of mercury . . $\frac{1}{6}$ grain.—M.

Three injections should be made daily, and the treatment continued for two or three days, in about which time the discharge will cease.

2. In chronic blennorrhagia a stronger solution can be used:

℞.—Water . . . . . ℥iijss.
Salicylate of mercury . . ¼ grain.—M.

In chronic cases the treatment should extend over a period of six or seven days, and in some stubborn cases even this is not sufficient. The solution has no irritative properties.—*Journal de Méd. de Paris*, April 21, 1889.

Surgical Treatment of Tubercular Peritonitis.—PROF. CECCHERELLI, in a paper read before the Surgical Congress at Bologna, described four cases of tubercular peritonitis in which he had performed laparotomy, washed out the peritoneal cavity with a solution of thymol, and powdered it with iodoform. In the first, a woman, aged twenty-eight, who, after suckling her fifth child, began to suffer from loss of appetite and swelling of the abdomen, the surface of the peritoneum was found reddened, œdematous, and studded with tubercles, whilst the cavity contained a large amount of fluid. Up to the date of the report (six months after the operation) she had remained well.

The second case was that of a boy, aged eleven, in whom slowly increasing ascites was the only symptom. The peritoneum was covered with tubercles. The operation got rid of the ascites, but a month later it had collected again, and laparotomy was done a second time with some benefit as regards the ascites; there were, however, signs of consolidation at one apex.

In the third case, that of a boy of thirteen, numerous firm adhesions infiltrated with tubercles were found; there was some improvement when he left the hospital, but a month later the belly had enlarged, there was dulness in the iliac region, and a feeling of hardness and resistance on palpation.

The fourth case was that of a girl aged eight, who had been ill for only a month, and who had dulness and harsh breathing at the right apex. The peritoneum showed thickened adhesions infiltrated with tubercles. Cultivation experiments gave negative results in this case as well as in the third, but in all the cases the specific microbe was seen with the microscope.

Prof. Ceccherelli thought the second case especially important, as the condition of the peritoneum found at the second operation showed the manner in which cure took place. Whilst the pieces of peritoneum removed in the first operation were studded both superficially and deeply with innumerable tubercles, those taken away at the second laparotomy showed none at all in some places, and in others the tubercles were surrounded by a covering of connective tissue of recent formation. Up to the present time, abdominal section for tubercular peritonitis had been performed by various operators in 88 cases with 52 cures and 25 deaths, whilst in 6 there was some improvement, and in five the result was unknown. Rabbits inoculated with the mesenteric glands of persons who had died of tubercular peritonitis developed purulent peritonitis, whilst the introduction of shreds of peritoneum obtained by laparotomy caused death in some rabbits. Prof. Ceccherelli had made a series of such experiments, and in all the rabbits on which he had succeeded in producing tubercular peritonitis he had performed laparotomy; the result would be published when the series was complete.

His present experience led him to the following conclusions: There are two forms of tubercular peritonitis, the dry and the ascitic. In the former case laparotomy is useless, because, owing to adhesions which it would be unsafe to break down, the peritoneal cavity cannot be explored. In the ascitic form of the disease laparotomy is of service, as it allows the cavity to be emptied, and excites adhesive peritonitis with fibrous transformation of the tubercles. Prof. Ceccherelli's views found little favor with his audience, Prof. Durante expressing the belief that whatever benefit was produced was merely temporary, and Drs. Bassini and A. Ferrari citing cases within their own knowledge in which patients had died of pulmonary phthisis from six months to two years after laparotomy.—*The British Med. Journal*, May 4, 1889.

Treatment of Tubercular Processes with Balsam of Peru.—PROF. ALBERT, in a lecture delivered before a medical society in Munich, spoke most highly of the efficacy of balsam of Peru as an application after operations for local tuberculosis. In all cases in which it was applied to the wound, healing was effected by first intention, and the tuberculous process was checked. In two cases, however, the action of the drug on the kidneys was decidedly unfavorable, it producing nephritis. Albert lays great weight upon using only the pure drug; many impure articles, he says, are brought into commerce under the same name.—*Münchener med. Wochenschrift*, April 16, 1889.

The Treatment of Chapped Nipples.—At University College Hospital, London, the favorite remedy for chapped and sore nipples is glycerine of tannin and sulphurous acid, each half an ounce, with one ounce of water.—*The British Med. Journal*, May 11, 1889.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE . . . . . $5.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JUNE 1, 1889.

THE TREATMENT OF HYDROCELE.

SEVERAL years ago it was thought that the treatment of hydrocele of the tunica vaginalis had been settled: that the best palliative treatment was simple aseptic tapping or aspiration; that the most safe and successful of the non-operative attempts at radical cure by obliteration of the sac was to be found in the injection into its cavity of iodine; and that absolutely safe and certain permanent cure could always be obtained by strictly aseptic incision and prolonged drainage.

That tapping is the best palliative measure still remains unquestioned, but not so with the other methods which we have mentioned, for Levis has urged the substitution of carbolic acid for iodine, and many operators have condemned the open drainage method from its infective risks, whilst others have strenuously urged the excision of the sac in all cases.

Of those who have made clinical comparisons of the various methods for the radical cure of hydrocele, probably none has exceeded in experience PROF. HELFERICH, of Greifswald. He, after experimenting on a very large scale, has (*Therapeut. Monatshefte*, Heft 3, 1889) returned to the above-mentioned tenets, which, as we have already said, several years ago were maintained by those most competent to judge.

Helferich at first had remarkably good results with the Levis method, but larger experience has made him change this view, for he has found iodine, though more painful than carbolic acid, decidedly more certain in effect, more speedy in point of return of the parts to natural condition, and less often followed by undesirable consequences.

Aseptic drainage is thought by him to be practically safe in the hands of an intelligent surgeon, and under these circumstances invariably certain. Bad results and relapses are not uncommon, it is true, but should we abandon all things which in ignorant hands may prove unfortunate, if, when applied by those who are competent, they are invariably followed by excellent result?

Nancrede has recently reported (MEDICAL NEWS, May 18, 1889) two cases, one from his own practice and one from that of Dr. J. M. Barton, of this city, in both of which, after failure of the iodine injection method, incision and drainage were performed and a small cartilage-like concretion found floating free in the sac. As Nancrede pointed out, these loose bodies in the cavity or wall of the tunica vaginalis are considered great rarities, but he offers the tentative theory that perhaps they are by no means so rare as we now imagine, and that possibly they are responsible for some of the failures met with by the injection method. The cases reported by Nancrede were afflicted with violent pains in the testicles when in a standing position, but these in both disappeared after the incision, finding and removal of the loose body, drainage, and subsequent absolute cure of the hydrocele.

The possibility of these bodies being present, especially when the injection method has failed and when pain in the testicles is complained of, offers another indication for incision and drainage; also an imperative reason for carefully exploring the tunica vaginalis in all cases so operated upon.

Excision of the sac, we are glad to find, is condemned by Helferich. It is an unnecessary and unsurgical procedure; accomplishing results no better, and often not even so good as simple drainage, and is attended with many risks not otherwise encountered.

MR. MORRIS (*Proc. Royal Med. and Chir. Soc. of London*, 1885–88, ii. 342) also has recently taken occasion to criticise unfavorably the operation of excision of the hydrocele sac.

The former status of the treatment of hydrocele may, therefore, be said to have remained unchanged by the large amount of clinical experimentation which during the past few years has taken place,

and that the spirit of the surgical world is that (1) aseptic tapping is the best palliative measure; (2) iodine injection is the most reliable non-cutting radical treatment; (3) aseptic incision with drainage is an invariably certain and safe procedure, and always to be preferred where choice lies with the surgeon.

THE PREVENTION OF DIPHTHERIA.

ONE of the most important practical bearings of modern bacteriological study is upon the subject of the prophylaxis of disease. Definite knowledge of the nature and biological characteristics of the exciting cause of any infectious disease enables us to direct our efforts at its prevention intelligently; we must destroy the specific microörganism involved. Our knowledge of the exciting cause of cholera, tuberculosis, and typhoid fever thus enables us to combat the spread of these diseases with a directness of purpose and assurance of success formerly quite impossible.

PRUDDEN'S careful investigation into the cause of diphtheria, the results of which have appeared in *The American Journal of the Medical Sciences* for April and May of this year, has added another to the list of diseases of which it may be said that the specific cause is known. We now know the exciting cause of diphtheria to be the streptococcus diphtheriæ, we know what will kill this germ, and its destruction is the definite end to be attained if we are to prevent the spread of the disease.

One of the greatest obstacles to real progress in the prevention of disease in this country is the persistence with which inefficient methods of disinfection are adhered to. The old sulphur fumigation is an example of this. So long as its use is advocated by our health officers it must be in vain that rational measures are recommended. The ease of its employment, coupled with the popular belief that it is all-efficient, makes it almost impossible that methods more difficult of application, though of established efficiency, should be introduced while its use is continued. It has repeatedly been shown that sulphurous acid gas does not destroy *all* germs, and Prudden has repeated the proof of its inefficiency so far as regards the specific microörganism of diphtheria. Notwithstanding all this, the New York State Board of Health, in a bulletin issued last week in regard to the prevention of diphtheria, places its main reliance on sulphur fumigation.

If we are to combat successfully the dissemination of disease, we must use only such means as are of known efficiency. All germs in each case must be destroyed. The prevention of each disease is a special problem, but we are, fortunately, in possession of two germicides which have thus far been shown to be efficient—carbolic acid and corrosive sublimate. These are unquestionably more difficult of employment than sulphur fumigation, but, while this may be regretted, it should not be an obstacle to the use of the more efficient agents, as fully described by Prudden in the article above referred to.

MIXED ANÆSTHESIA.

THE method of producing insensibility by the conjoint administration of narcotics and anæsthetics has been before the profession for a quarter of a century, but has never come into general use. It was originally recommended by Bernard, who found by experiment on animals, and his conclusions were subsequently confirmed on man, that when the administration of the narcotic preceded by some little time that of the anæsthetic, the amount of the anæsthetic required is less, that there is far less excitement attending the inhalation, and that there is less vomiting afterward. The narcotic, moreover, antagonizes the paralyzing action of the anæsthetic on the cardiac and respiratory centres and prevents subsequent shock.

In this country the mixed method was advocated by Dr. J. C. Reeve as early as 1876 (*American Journal of the Medical Sciences*), but it has never, neither here nor abroad, received the appreciation or attracted the attention it deserves. MR. ERNEST HART, in some recent notes on "Medical Paris" (*British Med. Journal*, May 11, 1889), states that for the last ten years the method has been used at the Sorbonne in anæsthetizing animals for experimentation, and without a single accident, whereas with the ordinary method the mortality from chloroform was one animal in three, and sometimes even greater.

The mixed method, as generally used in the human being, consists in injecting hypodermatically from $\frac{1}{6}$ to $\frac{2}{3}$ gr. of morphia and $\frac{1}{192}$ to $\frac{1}{80}$ gr. of atropia from fifteen to twenty-five minutes before the inhalation of the anæsthetic, just long enough for the effect of the narcotic to be fully felt by the nervous centres. In the production of artificial anæsthesia, and especially in cases of prolonged and severe operations, mixed anæsthesia appears to be most important for the comfort and safety of the patient, and is deserving of more general use.

THE advisability of removing the Medical Department of the University of Michigan from Ann Arbor to Detroit appears to be a question which is deeply agitating the profession of the two cities, and its correct solution is claimed to be of far-reaching importance to the interests of medical education in that State. *The Medical Age* has invited the opinion on the subject of prominent members of the profession in the State, and so far as they have yet replied they are stated to indicate a preponderance in favor of removal to Detroit.

AT their recent commencements the degree of Doctor of Medicine was conferred on graduates as follows:

Memphis Hospital Medical College	63
Long Island College Hospital	47
McGill University, Montreal	38
Omaha Medical College	7
University of Southern California	2

DR. HOWARD A. KELLY, of Philadelphia, has been appointed Gynecologist to the Johns Hopkins Hospital, and has resigned the Associate Professorship of Obstetrics in the University of Pennsylvania, to which he was elected a year ago. Dr. Kelly goes to Europe for the summer, and will enter upon his duties in Baltimore upon his return.

We understand that the vacancy at the University of Pennsylvania created by Dr. Kelly's resignation is not likely to be filled, but the work of the chair will probably be consolidated, and that in that event the duties will devolve upon Dr. Barton C. Hirst, the present Associate Professor of Obstetrics.

DR. CARLOS T. MACDONALD, Superintendent of the New York State Asylum for Insane Criminals, has accepted the appointment of President of the New York State Commission in Lunacy. Dr. Henry E. Allison, Assistant Physician of the Asylum at Ovid since 1877, has been appointed as his successor at the State Asylum at Auburn.

A NEW hospital building has been completed at New Brunswick, N. J., and handed over to the authorities having the management of the old City Hospital, who will abandon the rented building formerly occupied, and make a change of name to that of the John Wells Memorial Hospital. The new structure is the gift of Mrs. John Wells, who has caused it to be erected in memory of her deceased husband.

SOCIETY PROCEEDINGS.

THE AMERICAN SURGICAL ASSOCIATION.

Annual Meeting, held in the Army Medical Museum, Washington, May 14, 15, and 16, 1889.

(Concluded from page 584.)

WEDNESDAY, MAY 15TH.—MORNING SESSION.

DR. J. COLLINS WARREN, of Boston, read a paper on

THE EARLY DIAGNOSIS OF MORBID GROWTHS.

Reference was first made to the great desirability of some means of making an early diganosis in cases of possible malignant disease. The attempt to make a microscopical examination of morbid growths before their removal dates back to the earliest period of microscopical histology. The pain and danger of inflammation attending the methods adopted led to their abondonment. Antiseptic surgery, however, now enables us to perform such an operation almost with absolute certainty of absence of inflammation. Local anæsthesia with ether spray or cocaine renders the exploration free from pain. The instrument which the author employs consists of a small canula sharpened at the end. The calibre of the instrument varies from two to five millimetres. The instrument is used by gently rotating the canula between the fingers. After the instrument has penetrated the tumor to the desired depth it is withdrawn a short distance, and then entered obliquely so as to cut off the column of tissue. The piece removed may be as large as 5 mm. in diameter and 3 cm. in length, or even longer. The fragment can be at once examined by means of the freezing microtome or placed in alcohol and hardened. The operation can readily be performed at the physician's office and immediate diagnosis made. Several cases were reported illustrating the information obtained by the use of the canula. The instrument has been used in over one hundred cases, with little or no discomfort to the patient and with satisfactory results. It has been used in abdominal tumors; it has been used in one or two growths involving the abdominal parietes and peritoneum, but not in deep-seated organs. The object of the author in bringing the results of his observations before the Association was to show that modern improvements have made an old and discarded method not only practicable, but a valuable addition to our means of surgical diagnosis.

DR. F. S. DENNIS, of New York, protested against reliance upon this instrument in the diagnosis of malignant disease. He had never found pathologists willing to base a diagnosis of malignant disease upon the shreds of tissue removed by such instruments. More reliance is to be placed upon the clinical features than upon the microscopical appearances. Among these are age, situation of the tumor, the macroscopic appearance, pain, cachexia, lymphatic enlargement, hereditary influence, and finally, the use of the harpoon. While the harpoon or canula is a useful adjuvant, we cannot rely upon it absolutely in making the diagnosis.

DR. P. S. CONNER thought that there is nothing more definitely established than the difficulty of relying absolutely upon the microscopical examination in cases of supposed malignant disease. It is confirmatory testimony of great value. In the instrument presented we

have an additional aid to our means of diagnosis. While the points presented by Dr. Dennis are valuable, they do not aid much in the early diagnosis.

DR. R. A. KINLOCH, of Charleston, said that it is a well-established surgical principle that all tumors should be removed, so that the early diagnosis is, perhaps, not so essential. The question arises, whether it would not be better to remove the tumor and make the diagnosis of its nature afterward.

DR. W. H. CARMALT, of New Haven, said that in carcinoma and sarcoma the clinical features are, to his mind, a great deal more important than anything we can obtain from the microscope. Microscopical examination of different parts of the same tumor may present different appearances. Another point in regard to the use of the canula is the danger that the irritation excited by the instrument may convert a benign tumor into a malignant growth.

DR. WM. H. RICHARDSON had seen this instrument used in many cases without bad effect, and the microscopists consider that they derive valuable information from examination of the plugs of tissue removed. A correct diagnosis cannot be made in the earliest stages of malignant disease from the clinical evidence alone, and it seemed to him that in the early diagnosis this instrument affords valuable aid.

DR. L. MCLANE TIFFANY, of Baltimore, then reported a case of

FREE DIVISION OF THE CAPSULE OF THE KIDNEY FOR THE RELIEF OF NEPHRALGIA.

Four years ago he suggested the use of incision of the capsule of the kidney in the treatment of nephralgia. The patient, a woman, aged forty-nine years, white, married, had had gonorrhœa and syphilis. She had had abscess of the pelvis opening by the vagina, the discharge continuing for two years. Three years ago she experienced in the right loin sudden severe pain, lasting for a moment. It was supposed to be due to passage of a kidney stone. The attacks recurred at irregular intervals, the periods becoming progressively shorter, and the pain more intense. No calculi had ever been voided. Blood had been seen at rare intervals. The pain always began in the right loin midway between the pelvis and the ribs. It then extended toward the middle line of the body and down to the bladder and groin on the right side. Exertion was apt to induce it. Pressure over the right kidney caused acute pain, but no tumor could be made out. The urine was moderately acid, sp. gr. 1022, contained pus cells, and a few red blood-disks. There was no rise of temperature during the attacks.

The operation was performed January 12, 1889. The kidney, when exposed, moved freely during respiration. A deep stellate scar existed in the kidney, two inches from the lower end. No other abnormality was discovered. A sound was passed into the pelvis and a systematic exploration made, but no stone was detected; the capsule was then freely slit open for three inches, the edges of the cut gaped widely. The wound was then closed and an aseptic dressing applied. No urine passed by the lumbar wound. This soon healed, and since the operation, a period of four months, there had been no attacks of nephralgia.

DR. THEODORE A. MCGRAW, three months ago, operated on a woman on the supposition that there was a renal calculus. None was found, but the capsule was freely slit, and, since the operation, there has been no return of pain.

DR. F. LANGE, of New York, in one case of severe pain recurring at irregular intervals, operated with the expectation of finding a stone in the kidney, but none could be detected. He then proceeded in the manner described. The patient remained free from pain for three or four months, but the attacks then reappeared.

DR. W. W. KEEN, desired to refer to one source of error in the diagnosis of renal calculi which had not been mentioned. He recently operated on a case of tumor of kidney in which the needle, when it was passed into the substance of the organ, gave a distinct impression of coming into contact with a stone. The tumor was malignant and so adherent that it could not be removed. Subsequent examination showed that there was no calculus and that the needle must have come in contact with a calcareous vessel, of which there were several, or a mass of calcareous matter which was present.

DR. JOHN HOMANS, of Boston, recently operated in a case on a boy of fifteen years, who had a large swelling in the perineum. He removed by perineal section thirteen stones from the urethra, which would admit his forefinger. There was also a swelling in the loin which did not disappear after the operation. Three weeks later he opened the kidney through the right loin. He found a considerable quantity of pus but could detect no stone, although he was not sure that a stone was not present.

DR. J. M. BARTON, of Philadelphia, then read a paper on

DIGITAL DIVULSION OF THE PYLORUS FOR CICATRICIAL STENOSIS.

(See THE MEDICAL NEWS, May 25th, page 561.)

DR. R. A. KINLOCH had had no personal experience with this operation, but he could not understand how an organic stenosis of the pylorus is cured by a single dilatation. This is not the case with organic stenosis in other parts, as the rectum and the œsophagus. He was inclined to believe that where the benefit has continued for any length of time, the organic change has been slight. He could understand how benefit could be expected if the wound were kept open and the stricture systematically dilated.

DR. J. EWING MEARS, of Philadelphia, said that while it might not be easy to explain the results obtained by digital divulsion of the pylorus, there could be no question as to the beneficial results. The evidence of reliable operators certainly indicates that it is a proper operation and attended with successful results. This operation should always be preformed in preference to pylorectomy.

AFTERNOON SESSION.

DR. THEODORE A. MCGRAW, of Detroit, presented

A CONTRIBUTION TO THE HISTORY OF GUNSHOT WOUNDS OF THE ABDOMEN.

Reference was first made to a case of gunshot wound of the abdomen operated on by Dr. R. Abbe, of New York, July 8, 1886, in which four hours after the accident adhesions of the intestine to the abdominal wall were found, forming a cavity containing extravasated feces.

The adhesions were broken up, and four holes in the bowel and one in the bladder were closed. Suppression of urine and death followed. In August, 1887, the author was called to a case of gunshot wound of the abdomen, fourteen hours after its occurrence. At the operation it was found that adhesions had formed shutting off the peritoneal cavity. These were broken up and eight perforations of the bowel found; five of these had become so occluded by lymph as to be detected with difficulty, and no discharge could be forced through them. Four feet of the ileum were excised. The patient died twenty-six hours after the operation. A study of these cases led him to suggest that under such circumstances the drainage of the cavity would be the best plan to adopt. The artificial anus or fecal fistula could then be operated on at a later period. The question arises, whether or not these cases of early agglutination are sufficiently numerous to warrant our making them the point on which the treatment of all cases of penetrating wounds of the abdomen over six hours old must turn. This question cannot be decided at present.

A review of the approved methods of treating gunshot wounds of the abdomen was then taken up. The great danger has been shock. The shock has depended, 1st, upon the time occupied in operating; 2d, upon the amount of evisceration; 3d, upon the number and nature of the injuries to be repaired; 4th, upon the chilling of the intestines; and, 5th, possibly upon the long-continued anæsthesia. In discussing the subject the following propositions were considered, many of them based upon experiments upon dogs and sheep:

1. The gravity of an injury of this kind depends partly upon the size of the missile.

2. Gunshots which enter the abdominal cavity pass in a nearly absolutely straight line from the orifice of entrance, through the peritoneum, to that of exit or to their final stopping-place in the viscera. All apparent deviation of bullets fired into the abdomen, from a direct path, are due to changes in position subsequent to the shooting.

3. An incision made directly in the course of the ball, will give the shortest route to the injured viscera.

4. The contents of the bowels may be made to discharge through an open gunshot wound by manipulation and pressure.

5. An empty condition of the alimentary canal is most favorable to healing. To secure this it may be proper, in some cases of injury of the bowel immediately after a hearty meal, to evacuate the contents of the stomach by means of a siphon.

6. Agglutination and limitation of the morbid processes consequent upon gunshot wounds may take place as early as the sixth day.

7. Senn's method of hydrogen gas insufflation, however admirable in recent cases, should be used with great caution in cases four hours old, and especially in those made by small bullets.

8. The dangers of the operations for penetrating gunshot wounds of the abdomen are directly in proportion to the length of the operation and to the amount of the evisceration. The duration of the operation may be lessened: 1st. Making the incision on the line taken by the ball; or, if it has passed from before backward, over the point of entrance. 2d. By limiting the examination of the viscera strictly to such of them as may have been in the course of the ball. 3d. By suturing wounds of the intestine wherever it is possible, instead of excising them. 4th. By omitting all operative procedures, even suture, in wounds which have become so thoroughly occluded by plastic material that the contents of the bowel cannot be pressed through them. 5th. By operating first on those wounds which imperatively demand it, and leaving to the last those which may recover without operation. 6th. By never eviscerating a patient, except, first, when hemorrhage is otherwise uncontrollable; and, second, when there is evidently a discharging wound which cannot otherwise be found. The evisceration of a patient is as dangerous as any gunshot wound of the intestine which cannot be made to discharge its contents by manipulation or pressure can possibly be. There are cases where evisceration is necessary, but the author protested earnestly against the habit of eviscerating patients suffering from gunshot wounds of the abdomen as a matter of routine. We are not warranted in turning a man inside out and subjecting him to frightful danger in the mere fear that there may be still an undiscovered wound, when all the symptoms which ought to indicate such a wound are absent.

9. In cases of those wounds in which the patients may be too weak to endure any radical operation for their repair, efforts for their relief may be made by incision and drainage, and in some cases by attaching the injured intestines to the abdominal wall, as in gangrenous hernia. This procedure occupying but little time and making no draft upon the strength of the patient, may offer a hope of recovery which would not be possible under the expectant mode of treatment.

DR. D. W. YANDELL said that the statement in regard to the course of balls was new to him. A number of cases which he had seen had led him to believe that balls entering the abdomen might deviate very greatly. He was not altogether prepared to accept the statement at present. In one case in which the pistol held near the individual and in a straight line, the ball entered above the symphysis pubis and was found below the spleen, having wounded the intestines in its course. The recommendation that in extreme cases, where the patient is greatly exhausted, the wounded intestine be secured at the abdominal incision, is certainly conservative, and it seemed to him wise.

DR. C. B. NANCREDE, of Philadelphia, said that there are such a number of cases on record in which it was supposed that the balls were deflected, that he thought there could be no doubt that this occurs occasionally. In regard to the incision: from his experience with both the median and the lateral incision, he was forced to the conclusion, that unless we are certain that the bowel has followed an antero-posterior course, the median incision is to be adopted in every case with rare exceptions. He supposed that Dr. McGraw meant by evisceration, removal of the intestine *en masse*. It makes a great difference as far as shock is concerned, whether the intestines are removed all together or simply an inch brought out of the opening, immediately replaced and another portion examined, at no time exposing a large portion of the bowel. So many cases have been recorded in which death was the direct result of overlooking a single wound of the viscera or bloodvessels, that the only safe rule is to make a thorough examination before closing the abdominal viscera.

DR. J. EWING MEARS thought that the median incision is the one which should be adopted. It can be extended any desired distance, which cannot be done with the lateral incision. By the median incision the entire abdominal cavity can be inspected. In regard to what has been termed evisceration, he thought that it is better to permit the patient to die without operation than that an incomplete or imperfect operation should be performed, and that the surgeon would be almost criminally culpable if, after subjecting the patient to the dangers of an abdominal section, he closed the abdomen without satisfying himself by thorough examination that he had found every wound that had been inflicted.

DR. R. A. KINLOCH thought that after the abdomen is opened in a search for wounds every wound should be closed. We cannot say that one wound is of less importance than another.

DR. W. W. KEEN thought that, as regards the line of incision, we should make a distinction between stab wounds and gunshot wounds. In the former case the incision should be made at the point of the wound, while in the latter the almost invariable rule should be the median incision. He agreed with previous speakers that after we have opened the abdomen no case is properly treated if we leave by any possibility a single wound unsutured.

DR. C. H. MASTIN said in regard to the course of balls, that he had treated one case in which the ball entered one inch to the right of the umbilicus, made nine openings in the intestine, passed down through the bladder, out through the prostate, and lodged near the tuber ischii on the left side. The spinal column had not been injured.

DR. F. S. DENNIS, of New York, believed that it is a rule without exception that the median incision should be made where we are going to sew perforations in the bowel or stop hemorrhage in the abdominal cavity. The point of first importance is the control of hemorrhage. The median incision will permit the surgeon to enter the peritoneal cavity in half a minute.

DR. STEPHEN H. WEEKS had not heard any allusion in regard to the use of Dr. Senn's method. He laid stress upon two points: first, the use of the gas in determining whether perforation had occurred; and, second, in locating the openings in the bowel. This latter seemed to him a valuable point.

DR. STEPHEN H. WEEKS, of Portland, Me., then read a paper on

DRAINAGE AND DRAINAGE-TUBES IN THEIR APPLICATION TO THE TREATMENT OF WOUNDS.

He first referred to the great importance of drainage, and after alluding to the various methods proposed for securing it, described a new form of absorbable drainage-tube prepared from the arteries of animals. The arteries used are those of the ox. They are separated from their sheaths, cut into tubes four or five inches long, aud then boiled in water for about five minutes. This sterilizes them and hardens their coats. Holes are next cut in their sides, and they are passed over glass rods of different sizes, according to the size of tube desired. They are now placed in corrosive sublimate solution 1 to 100, and allowed to remain ten minutes. Then they are placed in alcohol 95 per cent., and at the end of twenty-four or forty-eight hours the glass rods are removed, the tubes being kept in alcohol until needed. These tubes are unirritating to the tissues; they are absorbed in from five to seven days, and drain the wound perfectly.

THURSDAY, MAY 16TH.—MORNING SESSION.

DR. JOHN HOMANS, of Boston, reported

A SUCCESSFUL CASE OF NEPHRECTOMY FOR REMOVAL OF CANCER OF THE RIGHT KIDNEY.

The patient, a woman of fifty, for a year had suffered with frequency of micturition. The urine had been dark and bloody at times. For three years she had suffered from indigestion. The tumor had been discovered in 1887, in the right iliac region, and since July, 1888, it had grown rapidly. It filled the right iliac region and more or less the umbilical and pubic regions. On palpation, large irregular nodules were felt, and in some parts there was fluctuation. Laparotomy was performed January 21, 1889. The incision was made in the linea alba, and was four inches in length. The tumor was exposed, and in the upper part were seen the remaining portion of the kidney and two large renal veins. These were tied with silk, the ureter was next tied and divided, and then the pedicle was readily ligated. The tumor was removed, a glass drainage-tube introduced, and the wound closed and dressed with iodoform gauze and absorbent cotton. The tumor measured six by nine inches and weighed fifty-three ounces. There was very little shock. The amount of urine since the operation has risen from ten to fifty-seven ounces, and has been gradually increasing. There was but little discharge from the drainage-tube, which was removed on the fourth day. One month after the operation an abscess was opened in the right lumbar region. A slight swelling and some tenderness still remain in the right loin. Whether these are wholly inflammatory or due to a recurrence of the growth cannot at present be determined. The patient is rapidly gaining strength. His experience led him to say that a large renal tumor which cannot be diminished in size by tapping (he would consider one weighing a pound or more a large tumor) can most conveniently be removed by an incision through the linea semilunaris or in the linea alba. Small tumors and those that can be diminished may be removed by the lumbar incision. In cases of moderate-sized kidneys, disorganized with pus or tubercular, or containing calculus, the lumbar incision is preferable.

DR. FREDERICK E. LANGE, of New York, said that in cases in which a large tumor of the kidney is to be removed, and it is desirable not to open the peritoneal cavity, he had found a trapdoor incision with exsection of one or two ribs, if necessary, gave ample room for operation. He had operated nine times, but never for neoplasm. With free incision and open antiseptic after-treatment, he regarded extirpation of the kidney, even in cases of large tumors, a comparatively safe operation.

DR. M. H. RICHARDSON said that there is a frequent anomaly of the vascular supply of the kidney which should be borne in mind in operations. Instead of one renal artery there may be three or even four arteries. If such a pedicle is ligated *en masse*, there is danger of slipping of the ligature and hemorrhage. This is obviated by tying the pedicle in several sections.

DR. LEWIS S. PILCHER, of Brooklyn, then read a paper on

THE QUESTION OF THE ANTI-TUBERCULAR POWER OF IODOFORM, WITH A SUGGESTION FOR A MORE EXACT CLINICAL TESTING OF THE SAME.

The paper first called attention to the different results obtained by the application of iodoform to tubercular tissues, according as the results were derived from clinical experience or from observations on tubercular affections artificially induced in animals. The following case was a contribution to the study of this question.

A girl, aged thirteen years, with a family history of tuberculosis came under observation with an infiltrated and ulcerated patch on each leg; there was also on each thigh an infiltrated patch without ulceration. The disease was of three months' standing. The diagnosis of tuberculosis of skin was made. The patch on the right leg was excised and microscopical examination confirmed the diagnosis; tuberculous nodules with bacilli were found. The patches on the thighs were also excised and healed without further treatment. Bismuth was applied to the patch on the right leg and healing progressed satisfactorily. It was then determined to apply skin-grafts. The sore was curetted, the grafts applied and did well for a time. Later the epithelial elements broke down and a number of small ulcers formed. At the base of each ulcer was found a particle of bismuth. Portions of the tissue removed, however, showed no bacilli. No iodoform had been employed. Boracic acid ointment and the occasional application of nitrate of silver were now ordered. The ulcer on the left leg was curetted Dec. 10, 1888, sprinkled with iodoform and covered with absorbent cotton. It rapidly healed and on Jan. 25th a wedge-shaped piece was removed and examined. It was entirely free from evidences of tuberculosis. A soft natural skin has since formed.

The committee appointed to take action in regard to the

DEATH OF DR. S W. GROSS,

presented the following:

Whereas, it has pleased the Almighty to remove from our midst, Dr. Samuel W. Gross, who assisted in founding the American Surgical Association and contributed by his example and work largely to its success, who as a teacher was enlightened and impressive, as an author was accurate and original, as a surgeon was sound in judgement, rich in clinical experience, skilled in manipulation, and as a Fellow was genial and courteous; therefore, be it

Resolved, that the Association deplores his death as an irreparable loss, and directs that a copy of the foregoing be spread upon its minutes and forwarded to his bereaved family.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—D. W. Yandell, M.D., of Louisville.

Vice-Presidents.—Claudius H. Mastin, M.D., of Mobile; C. B. Nancrede, M.D., of Philadelphia.

Secretary.—J. R. Weist, M.D., of Richmond, Ind.

Treasurer.—P. S. Conner, M.D., of Cincinnati.

Recorder.—J. Ewing Mears, M.D., of Philadelphia.

Council.—Drs. John S. Billings, L. McLane Tiffany, W. F. Peck, and F. S. Dennis.

Chairman of Committee of Arrangements.—J. S. Billings, M.D., of Washington.

The following were

ELECTED MEMBERS:

Drs. Stephen H. Weeks, of Portland, Me.; Robert F. Weir, of New York; John Homans, of Boston; Lewis A. Stimson, of New York; Fredrick E. Lange, of New York; Lewis S. Pilcher, of Brooklyn; Levi Cooper Lane, of San Francisco; Arthur T. Cabot, of Boston.

The Association then adjourned to meet in Washington on the second Tuesday in May, 1890.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

THE PRESIDENT, W. W. KEEN, M.D., IN THE CHAIR.

Stated Meeting, May 8, 1889.

DR. ROBERT ABBE, of New York, read a paper on

INTESTINAL ANASTOMOSIS.

(See page 589.)

DR. JOHN ASHHURST, JR., considered this plan of lateral anastomosis to be one of the greatest improvements made in this department of surgery. He had not had the opportunity of using either the bone plates of Prof. Senn or the catgut rings of Dr. Abbe, but was disposed to think that the rings are better than the plates. Besides giving a larger opening, they would seem to be more easy of adjustment, more likely to adapt themselves to the shape of the parts, and more apt to effect accurate apposition. The suggestion of Dr. Abbe that the two portions of gut should be so placed that the peristaltic wave may be continuous, seemed to be also of much value. One would certainly suppose that this would render the restoration of natural function easier than for the intestinal contents to be made to turn a sharp corner, as it were, in passing from one portion of the bowel to the other.

DR. C. B. PENROSE said that his experience with this operation of intestinal anastomosis was limited entirely to experiments on the dog. Instead of using the bone plate of Senn or the catgut ring referred to by Dr. Abbe, he used a rubber ring sewed together with catgut; instead of using silk sutures he employed catgut. In five or six days the catgut would be absorbed, and the rubber would adapt itself to any shape for passage through the intestinal tract. In all cases the rings passed within ten days after the operation. There is no advantage in this method over those mentioned, except that the material employed may be obtained when bone or catgut is not available. The rubber disks can be cut of the necessary size and shape from ordinary sheet rubber. In most of his experiments, instead of using reinforcing Lembert sutures, he placed a circular omental graft around the line of union.

DR. ASHHURST did not understand Dr. Abbe to recommend that intestinal anastomosis should be adopted in the treatment of intestinal obstruction, but in cases of fistula which may result from obstruction or other causes. He thought it a well-established fact in surgery that the line of safety in intestinal obstruction in which it is necessary to remove a portion of the bowel, is to estab-

lish a temporary false anus, and to postpone to a subsequent occasion the attempt to restore the continuity of the bowel by this or some other method. The only exception recognized is where the portion of the bowel removed is so high up or where it is so large that a great portion of the intestine would be thrown out of use. For instance, if it were necessary to remove a portion of the jejunum high up, the establishment of an artificial anus would leave so small a portion of the bowel for digestion, that the patient would starve to death, and in such a case it would be proper to endeavor to restore the continuity of the gut at once, although the immediate danger of the operation would be thereby increased. Where, however, the portion removed was lower down in the small intestine, or in the large intestine, the proper course would be to make a temporary artificial anus, let the patient get over the effects of the obstruction, and at a future time endeavor to restore the continuity of the bowel by whatever method might seem proper.

Dr. John B. Roberts vividly recalled a case that he lost because he was not sufficiently familiar with these operations to shoulder the responsibility of making an artificial anus. This case was seen shortly after Senn's method had been described. He was called to operate on a strangulated hernia in the conntry where the patient could not receive much subsequent surgical attention. He found the bowel pretty blue. He debated some time whether it would be better to make an artificial anus or return the bowel. He thought that he had seen the circulation return in bowels as blue as this one, and taking all the circumstances of the case into consideration, decided to return the bowel. The external wound healed rapidly and well, and everything appeared to be right, when suddenly on the fifth or sixth day, in the absence of the attending physician, the patient was seized with intense abdominal pain and expired in a few hours from what undoubtedly was a perforation made by a slough of the intestinal wall. If he had been present, he would have done an immediate laparotomy. He thought that if he had such a case, after hearing this paper, that he should be much more likely to make an artificial anus, and run the risk of curing it subsequently by intestinal anastomosis.

Another indirect result of this method of operating will be that we shall deal with malignant disease more satisfactorily than has been the case heretofore. After making this artificial anastomosis in a case of malignant disease of the intestine, it becomes a proper question whether at a subsequent time the abdomen should not be opened and the cancerous mass be excised with the hope of a radical cure. He believed that in many cases of malignant disease, early, radical, and repeated removal may finally effect a cure. He did not see why with this method we cannot attack malignant disease of the intestine at a much earlier period. He had never been inclined to adopt the excisions done at Vienna and other places for intestinal and pyloric malignant growths, but with lateral anastomosis there is possibly a chance for a safe or even a radical cure by operation.

Dr. M. Price said that this paper three months ago would have been of vast service to him. He had a case of strangulation the result of epithelioma involving four inches of the bowel, the obstruction being almost complete. The obstruction had continued eleven days, but the patient was in moderately good condition. With the method which had been described it would have been easy to unite the two portions of bowel, and this would have saved an immense amount of trouble and annoyance. The patient is of a nervous, irritable temperament, and the application of Dupuytren's instrument causes great annoyance. The subsequent management of the case will probably be difficult, unless this method be adopted. The belly is large and flabby, and the closure of the external wound will probably be a matter of difficulty.

In pelvic work it is impossible in some cases to avoid tearing the bowel; having such an easy method of closure he should not fear the result. He should have no hesitation in cutting out a portion of the bowel diseased and thickened, which offers very little chance of good recovery, and bring the portions of the bowel together by the method suggested by Dr. Abbe.

Dr. J. M. Baldy spoke of the comparative value of the three materials which have been mentioned. One great objection to the bone plate of Senn is the small calibre of the opening which results. Again, the material must pass by the bowel, and in doing so the piece of bone may possibly cause damage. To a great extent these objections are obviated by the rings of catgut. If these rings are examined closely, it will be seen that they are very hard, large, and thick, and that it would be improbable that they should be absorbed in the length of time it would take for them to become loose. In ten days the rings used by Dr. Penrose had passed. We should not expect this ring of catgut to be absorbed in that time. If it should not be absorbed, it would not pass as readily as the rubber ring. The latter would cause no more trouble than so much tripe. The rubber rings could be readily kept for any length of time. The catgut rings, as Dr. Abbe explained, must be kept under compression in some solution, and must be carefully prepared by a comparatively tedious process. This is all obviated in the rubber ring. The approximation by rubber seems to have some advantage over catgut, and the catgut is a most decided advance on the bone plates.

The President, Dr. W. W. Keen, desired to say a word in regard to one of the cases narrated by Dr. Abbe. He was present at the operation, and certainly a more unfavorable case could not be imagined. The woman appeared upon the verge of the grave, and he expected to hear of her death in the course of a week, if not even earlier. It seemed impossible that she should recover, not only from the great emaciation, but also from the operation, which was necessarily very prolonged and very difficult, in consequence of the matting together of the intestines and surrounding parts. He certainly thought that we are to be congratulated upon having such a valuable paper upon such an important topic, and that Dr. Abbe is to be congratulated upon such favorable results in such an unfavorable case.

He could hardly agree with the last remarks of Dr. Ashhurst, in reference to making an artificial anus rather than performing immediate lateral anastomosis of the bowel. This seemed to expose the patient to a greater risk, as it involves the performance of two operations instead of one; one an operation of necessity when the artificial anus would be made, and second a laparotomy when the lateral anastomosis would be made, which always involves some risks. He could see no valid reason why a patient requiring the formation of an arti-

ficial anus, in many if not in most cases, might not have the advantage of immediate lateral anastomosis, and thus avoid two operations, as the lateral anastomosis operation would be hardly more prolonged and involve no greater risk than the formation of an artificial anus, if, indeed, it is attended with as much risk. If he correctly understood the paper, this method was proposed not only for the relief of existing fecal fistulæ, but also for other conditions, such as shot-wounds, excision of the bowel, etc., which would require the formation of an artificial anus.

DR. ROBERT ABBE said that he spoke of the use of this method in the immediate apposition of the intestine in dangerous cases, but he did not intend to emphasize this point. He was rather inclined to agree with Dr. Ashhurst in thinking that an artificial anus should be established. The discretion of a surgeon of considerable experience will, however, allow him to make immediate apposition in certain cases, but, for universal recommendation he thought that often it would be attended with additional risk. If the patient may be hastened over the shock and an artificial anus established in a few moments, the second operation for anastomosis under favorable circumstances is attended practically with little risk. In cases of serious obstruction, lasting for three or four days with shock and intestines over-distended, he thought an artificial anus should be established.

With regard to the suggestion of Dr. Penrose, he thought that some such device as he suggests may succeed everything that has yet been thought of. He did not vaunt the use of catgut rings as having any supremacy. Senn's plates have advantages; in gastro-enterostomy they would be less easily digested than the catgut, but these simple rings have two or three undoubted advantages. With regard to the absorption of catgut, it occurs in less than ten days. In both of his earlier specimens the catgut is gone, and in these the intestine was removed at the end of nine days. It will probably be absorbed in four or five days.

The catgut rings when taken out of the alcohol and put in the intestine swell a little, giving additional firmness and very tight apposition. Senn, in his experiments, oftentimes found the plates plugged by hair, straw, etc., which the dog had swallowed. This built up an obstruction at the operated part which produced serious trouble. These rings, on the contrary, have a very large aperture from the first—as large as two inches. In this narrowed form it slips readily into the incision in the bowel which closes over it, while the diamond-shaped plates of Senn cause a curling over of the edge of the stretched small intestine. When the outside sutures are applied with catgut rings there is from one-fourth to one-half an inch of the two serous coats in contact. If we have more than that, as we do with bone plates, we take something from the lumen of the bowel which would be better left.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON PÆDIATRICS.

Stated Meeting, April 11, 1889.

J. LEWIS SMITH, M.D., CHAIRMAN.

DR. T. H. HOLGATE read a paper on

THE TREATMENT OF NÆVUS

and reported some good results from injections of alcohol into vascular tumors. After giving a detailed account of all the methods of treating nævus, such as injections of many different substances, external applications of astringents, caustics, the actual cautery, electrolysis, vaccination upon vascular excrescences, ligature beneath pins, double ligature, setons, etc., he presented a boy four years of age, whose vascular tumor, as large as a filbert, and located on the right ala nasi, had almost completely disappeared after injecting, by means of a Pravaz syringe, a few drops of ninety-five per cent. alcohol. These injections were repeated several times, whereupon the tumor hardened and the skin became pale.

His second case was a child two months old, with a vascular tumor upon the chest. One injection of alcohol was made and the injected fluid confined *in loca* by means of a ring pressed down upon the parts. The tissues whitened in a short time, leaving no scar and but a small portion of the original nævus. In conclusion, Dr. Holgate said that he had no knowledge of alcohol having been used for the purpose by any one else, and he believed that this method, if properly carried out, would constitute a satisfactory treatment for nævus.

DR. HEITZMAN took exception to the term nævus (birth-mark); he would prefer the more scientific name angioma. The treatment of angiomata would depend upon their either being flat, lobular, or cavernous. He had seen no good results from sodium ethylate or electrolysis. He removes small angiomata by means of curved scissors, large and superficial ones with nitric acid. In the cavernous variety he employs nitric acid on a pointed hickory stick which is pushed deep into the tumor. He would give alcohol a trial.

DR. FOX remarked that the cavernous variety will probably not be cured by alcohol. He found electrolysis efficacious and manageable in wine marks, giving fair results. A cambric needle connected with the negative pole of the battery will transform dark into light spots. He had tried linear scarifications with poor success, and referred to Mr. Churchill's work on *Foot and Face Deformities*, in which a red-hot needle is highly recommended.

DR. GERSTER remarked that the location and form of the new growth determine the treatment. Injections of alcohol into goître had been practised in Vienna. One fatal case had occurred in Billroth's clinic after injecting one-half ounce of alcohol, acetic acid fermentation and sepsis taking place. The fatal result was evidently due to septic material introduced at the time of injecting and not to the alcohol. Hollow needles must be absolutely aseptic.

Alcohol injections may be good in nævus of limited extent. Personally, he employs the knife and actual cautery. When the pointed cautery is used it must be rotated in and about the vascular tumor from one single or central puncture. An angioma in the lips or cheeks may occasionally be approached from the side of the mucous membrane, thus avoiding an external scar.

DR. CAILLÉ had treated a number of vascular tumors successfully with the actual cautery. Alcohol injections might be useful and should be tried, the more so as there are a number of cases on record in which alcohol injections into the tissues had been successfully employed to set up inflammatory adhesions and radically cure hernia in children.

EIGHTH GERMAN CONGRESS OF INTERNAL MEDICINE.

Held at Wiesbaden April 15th to 18th, 1889.

(Specially reported for THE MEDICAL NEWS.)

(Concluded from page 559)

DR. KRAUSE, of Berlin, read a paper

ON THE TREATMENT OF LARYNGEAL TUBERCULOSIS.

In cases of laryngeal tuberculosis he has often used surgical treatment, and has found that tracheotomy, which had been recommenced by Schmidt in 1880, has rendered excellent service to the organ, giving it absolute rest, which favors the curative processes. But the preëxistence of pulmonary tuberculosis and its rapid development may be a contraindication to this operation; on the other hand, we must not forget that the removal of the canula is far from being devoid of danger. He then communicated the results which he had obtained by means of curetting.

The local treatment by lactic acid, after four years' experience, has left a good impression on him, and he thinks it useful especially against the symptom pain.

The cases of laryngeal tuberculosis which he has treated at the Berlin Polyclinic during these past four years, he has divided into two classes: 1st, Mild cases, amongst which he has classified paresis or laryngeal catarrh accompanied by tuberculous pulmonary lesions. 2d, Severe cases, which include tuberculous ulcerations, infiltrations, and erosions.

In 1885, 607 persons were treated at the clinic—out of which 67 suffered from laryngeal tuberculosis, 42 were mild cases and 25 severe cases.

In 1886, 986 persons presented—of which 113 were cases of laryngeal tuberculosis, 46 mild cases and 67 severe ones.

In 1887, 1363 persons—149 tuberculosis of larynx, 65 mild and 84 severe cases.

In 1888, 2285 persons—240 laryngeal tuberculosis, 127 mild and 113 severe cases.

Out of the 289 severe cases, 58 underwent the curette treatment, plus 13 cases in his private practice, which give him a total of 71 cases, out of which 41 were completely cured—or at least there was a remarkable amelioration with disappearance of the painful phenomenon, for where non-cicatrized ulcerations persist one cannot admit a cure from an anatomical point of view.

Out of those patients which are recorded in his statistics, 16 are cured up to the present and the disease has shown no signs of return, 12 are still undergoing treatment, and 7 died, but not as a result of their laryngeal tuberculosis. Several patients have been lost sight of; in 15 he observed a recurrence of the disease.

In unfavorable cases, he has had to deal with a very generally developed cachexia with advanced pulmonary and laryngeal lesions, or again with lesions showing a great tendency to recur. In such cases, however, we must not give up all local therapeutical means, and if this last procedure is not successful, we must use the intervention of a general treatment. Under such circumstances, the establishment of hospital sanitariums would be very useful to the working classes. As to the wealthy patients, he did not think that they ought to be sent indiscriminately to winter resorts, on account of the bad hygienic conditions in which they place themselves during their travel or stay in such places, when their lesions have just begun, allow them to lead a life detrimental to their final cure.

M. SCHEINMANN, of Berlin, from observations made at the Berliner Polyclinic, in cases of phthisis, stated that therapeutical success seems to depend more on the earliness of the diagnosis on the one hand and to local treatment on the other. Amongst the methods employed at the Berlin Polyclinic, incisions, curetting, scarifications, cauterizations by means of lactic acid, have all given favorable results, provided the correct method has been applied in each case; often, also, surgical means have been used in conjunction with medical applications. Surgical intervention, however, must be resorted to only in cases in which the local lesions and general state of the patient allow it; when contra-indications to surgical means appear to exist or when a more simple treatment from a technical point of view is sufficient, the use of menthol is one of the local medications most to be recommended.

DR. STORCK, of Copenhagen, then described a

SIMPLE PROCESS FOR ASPIRATING LIQUIDS FROM SEROUS CAVITIES.

In cases of empyema and ascites, he replaces the apparatus of Dieulafoy, Unverricht, Quincke or Fürbringer, which get easily out of order, by Bunsen's aspirator, such as is used in chemical laboratories to hasten filtration of liquid. The trocar or drainage tube is put in direct communication by means of a soft tube (in the course of which we may place a recipient, which will enable us to recognize the pathological fluid) with a bottle having two openings, and previously filled with water, and in which the flowing out of the liquid, which falls into a vase placed beneath it, brings about an aspiration analogous to that of an air-pump. He has taken out by means of this apparatus, more than twelve quarts of ascitic liquid, also pus in empyema, with most satisfactory results.

PROF. LEYDEN, of Berlin, said that we cannot speak definitively of the value of the operation in empyema; many patients can hardly resist the operation, and in young children it is difficult to obtain the necessary immobility; in each case we must not overlook the general state of the patient.

The Congress then adjourned to meet again at Wiesbaden in April, 1890.

CONGRESS OF THE GERMAN SOCIETY OF SURGERY.

Eighteenth Annual Session.

Held at Berlin April 24th to 27th, 1889.

(Specially reported for THE MEDICAL NEWS.)

The eighteenth German Congress held its first meeting on April 24th, under the presidency of PROF. VON BERGMANN.

PROF. VON ESMARCH, of Kiel, read the first paper, which was on the

ETIOLOGY AND DIAGNOSIS OF CANCER OF THE LIPS AND TONGUE.

We meet with ulcerating tumors analogous to cancer throughout the whole organism, but they are more often

met with on the lips or tongue (syphilitic or tuberculous tumors, or, again, affections of microbian origin). The appearance and the mode of development of these tumors do not allow us to differentiate them easily from carcinoma, and they require a different treatment from cancer, which demands radical extirpation, while other tumors permit of internal treatment and are curable by a less radical surgical interference. In all cases, however, in which a large operation is to be performed, a microscopical diagnosis ought to be made. This histological examination ought even to be several times repeated and tissues at different depths taken.

When the tumors are easily reached a special trocar is used, which allows, at the same time that the puncture is made, the withdrawal of a small piece for microscopical examination. Syphilitic tumors are those which are most liable to occasion faulty diagnosis. Sarcomas of muscular tissues are mostly nothing but syphilomas, which is the reason why we most frequently find that syphilomas of the tongue and lips are, for the most part, constituted by muscular tissue. Syphilomas can manifest themselves many years after infection.

When in microscopical examination the fragment of the tumor does not show any alveolar structure, epithelial agglomerations, cancroidal pearls, tubercular bacilli, stellated rays as in actinomycosis, but, on the contrary, a tissue of granulation, of recently formed connective tissue, of fusiform cells, one can then make, by exclusion, the diagnosis of syphiloma, even if no traces of hereditary or acquired syphilis should exist; the antisyphilitic treatment must then be resorted to immediately. Iodide of potassium is the preparation he first gives, then the mercurial or arsenical preparations; this antisyphilitic treatment must be kept up for a long time—months may be necessary before any action can be found. Great care must be used with benign syphilitic tumors, they must not be taken away with the knife, for it may bring on a rapid recurrence and give a malignant tendency to the affection.

Returning to the etiology of cancer, many possible causes have been given: wounds, penetration of a foreign body into the parts, such as tobacco, cicatrices after burns and operations. In addition, benign tumors can be transformed with time into a malignant type, such as verrucosa, nævus, papilloma, condyloma, atheroma, syphiloma. Chronic irritation of the skin or mucous membrane can also give rise to malignant tumors. Another cause of cancer, according to Virchow, is the feeble resisting power of certain tissues by predisposition.

It probably is the diminution in the resistance of the inflamed tissues which helps or allows the penetration of the connective tissue by epithelial cells; this would be the way of explaining the chronic irritation which seems to play such a prominent part in the etiology of the cancers of smokers. As to the heredity of malignant tumors, it is more an hereditary tendency to connective tissue proliferations, and he thought that hereditary syphilis, and especially the one that has passed through numerous generations—ancestral syphilis, plays an important pathogenic *rôle* in the production of connective-tissue tumors. Now, is the origin of epitheliomas an analogous one? He thought it was, and that ancestral syphilis still exerts its influence in such cases, for cases in which there exists an epithelial proliferation, such as xeroderma, eczema, psoriasis, are transmissible by heredity. As an example, he presented a drawing of three patients suffering from xeroderma; two brothers and a sister, whom he had often seen at his clinic; their lips were completely covered with pigmentated vegetations. In such cases he thinks it necessary to interfere very promptly to prevent a subsequent transformation of the disease into a malignant tumor.

DR. HEIDENHAIN, of Berlin, then read a paper

ON THE CAUSES OF THE LOCAL RECURRENCE OF CANCER AFTER EXTIRPATION OF THE MAMMARY GLAND.

He had made an histological examination of eighteen cases of cancer of the mammary gland for primary cancer. In all cases in which there had been a recurrence he was able to make out by microscopical examination that fragments of cancer had remained in the wound after the operation. If it is easy to see infiltrated lymphatic glands, it is not easy to see by the naked eye if the tumor has been completely removed. In the eighteen cases which he had examined, he had tried to ascertain whether in the section of the tumor which was in contact with the healthy tissues, he would find healthy or diseased tissue; on the presence of healthy or diseased tissue would depend the recurrence of the disease. He examined in this manner several fragments of each tumor; in twelve cases he had found the tissues infiltrated with epithelial rays, and out of these twelve cases there had been eight recurrences, one death as a result of the progress of the cancer in the other non-operated mammary gland, another patient had disappeared, and the two others remain well. In six cases he had found only healthy tissues, and in those six cases the carcinoma has not reappeared up to date.

In cancer of the breast, the epithelial extensions follow the lymphatic vessels and extend often to the pectoral aponeurosis; it is, therefore, very important to take away the aponeurotic covering of the pectoral muscles, and even to cut into the muscle so as to be sure that the lymphatic vessels, which cross the aponeurosis perpendicularly, are not infected. For a long time Dr. Küster has been in the habit of taking away this aponeurosis, because of the bad prognosis presented by cancerous tumors which are adherent to the pectoral aponeurosis.

Out of sixty-five cases in the practice of von Volkmann in which the tumor was adherent to the pectoral aponeurosis two were cured, and in all the others the disease has returned. Out of twenty-one cases of the same kind operated on by Küster, but a single one is still alive, and she has a return of her trouble; hence, when the tumor is adherent, it is well to take away a good part of the muscle and to clean it thoroughly, so as to be sure that the whole growth has been removed.

MR. VICTOR HORSLEY, of London, then read a paper on

THE METHODS OF DIAGNOSIS OF LESIONS OF THE MOTOR ZONE OF THE CEREBRAL CORTEX.

He desired to expose the principles according to which one can establish with certainty the diagnosis of the seat and the nature of the lesions in partial epilepsy of the motor zone of the cerebral cortex. The function of the motor zone is a triple one: 1. Tactile sensation; 2. Muscular sensation, locomotion, and movement; 3. Coordinate motor force. This motor zone can be involved by a lesion which is either exciting or depressing. An

excitation shows itself ordinarily: 1. By a sensitive aura, which consists in a sensation of itching; 2. By tonic and clonic movements; the clonic movements are met with in tumors of the cortex, while the tonic movements are more a lesion of continuity.

Beevor and himself have made experiments on the monkey, and have succeeded in analyzing in a more precise form the motor function. As a result of their experiments, confirmed by clinical observations, there is found in the motor zone of the cerebral cortex centres for the localization of movement of each segment of an extremity; for example, for the index, the thumb, the fingers, the wrist-joint, the elbow, the shoulder, etc. At the first excitation there can be produced a movement of one or two segments of this extremity—for example, the flexion of the thumb; at the second and third excitation one can obtain a typical case of Jacksonian epilepsy. If one destroys one of those motor centres, a paralysis with a loss of sensibility and movement is produced. If, however, the destruction of the centre is not complete, even if movements are still present, there is a loss of the topical localization; the animal still feels, but cannot exactly determine the seat of the tactile or painful sensation. Charcot has for a long time made these same experiments on the localization of movements in hysteria. The temperature on the paralyzed side and on the healthy side presents the same variations as in recent hemiplegias as to the secretions of the glands of the skin; injections of pilocarpine by Strauss have shown a diminution in the secretion on the paralyzed side.

DR. K. SCHUCHARDT, of Halle, then read a paper on

THE NATURE OF OZÆNA.

The different theories which have been formed to explain the fetidity of ozæna are very unsatisfactory. This odor has been attributed to the neighboring cavity of the nasal fossa; but this explanation is not sufficient, for the nasal mucous membrane is itself deeply involved. Others have hunted after a specific microörganism without any satisfactory results. Dilatation of the nasal fossæ occurring as a result of atrophy of the turbinated bones does not suppress the ozæna. Still Zuckerkandl has found no case of ozæna in congenital atrophy, and for a number of years von Volkmann has obtained in recent cases of ozæna a great amelioration of the disease by means of dilatation of the nasal fossæ. This enlargement is obtained by excising a large part of the turbinated bones. In fragments obtained from such resections the author has found that the cylindrical epithelium of the nasal mucous membrane was transformed into pavement epithelium. In a great many cases he has examined the secretions from ozæna, and has found a great many microörganisms in pavement epithelial cells, and sometimes cells of the buccal cavity. He has, moreover, found pavement epithelial cells half the size of the normal ones, and which he considers as an epithelium of transition between cylindrical and pavement epithelium. A study of the fragments obtained by excision has shown a mucous membrane devoid of glands and transformed either into a tissue of granulation or into cicatricial tissue, and constituted by ten or twelve layers of pavement epithelium. The cells of the upper layer were quite analogous to those of the epidermis. This epidermoidal tissue increases more and more, a mass of dead epithelial cells is formed which putrefies, and the accumulation of which becomes dangerous. He thought it important to draw attention to the fact that in mucous membranes where the cylindrical epithelium is transformed into the pavement variety, it is not a rare fact to see a cancroid appear in the future.

DR. PETERSEN, of Kiel, then read a paper on

A NEURALGIC AFFECTION OF THE KNEE.

He had treated a patient presenting all the symptoms of an articular affection of the knee with intense neuralgic pains accompanied by fever. Massage had been employed with negative results. He placed a plaster bandage, which he allowed to remain in position for ten months and a half, after which time he took away the bandage and allowed the patient to walk about; pain soon returned, accompanied by swelling and fever. He then decided to have recourse to an operation, but found nothing abnormal in the peri-articular tissue nor in the synovial membrane. The patient was cured without any rise of temperature, and presented after the operation symptoms of hyperæsthesia, which she had never felt before, besides other hysterical phenomena, but the articular pain had disappeared.

PROF. VON ESMARCH had observed a case of neuropathic coxalgia in an hysterical woman, who presented all the symptoms of hereditary tuberculosis, and even had tubercular glands, with fever in the evening. He tried five times to immobilize the parts with a plaster apparatus, and five times the pains and fever disappeared, but the affection would return as soon as the apparatus was removed. He then decided to open the articulation, but found no traces of inflammation, all the articular tissues being healthy. Cure was rapid; fever disappeared, and to-day the patient walks perfectly well, without any pain.

(To be continued.)

NEWS ITEMS.

The Staff of the Johns Hopkins Hospital.—The Trustees of the Johns Hopkins Hospital have accepted and approved the following appointments:

Hospital Staff.—Physician-in-chief, Dr. William Osler; Pathologist, Dr. W. H. Welch; Chief of Dispensary, Dr. W. S. Halsted; Resident House Physician, Dr. H. A. Lafleur; Resident House Surgeon, Dr. F. J. Brockway; Assistant House Physician, Dr. Harry Taulmin; Assistant House Surgeon, Dr. G. E. Clarke. Consulting Physicians and Surgeons—Dr. Alan P. Smith, on the part of the Hospital Trustees, and Dr. James Carey Thomas, on the part of the University Trustees, and Dr. I. E. Atkinson, Dr. S. C. Chew, Dr. Frank Donaldson, Dr. W. T. Howard, Dr. Chris. Johnson, Dr. T. S. Latimer, Dr. F. T. Miles, Dr. G. W. Miltenberger, Dr. L. McLane Tiffany, and Dr. H. P. C. Wilson.

Dispensary Staff.—Chief of surgeons, Dr. W. S. Halstead, with the assistance in general surgery of Dr. James Brown and Dr. J. M. T. Finney, and the resident house surgeon, with Dr. S. Theobald in charge of the Diseases of the Eye and Ear, and Dr. R. B. Morrison in charge of the department of Diseases of the Skin.

Chief Physician, Dr. W. Osler, with the assistance of Dr. William D. Booker, in the treatment of Diseases of Children, and Dr. H. M. Thomas in the treatment of Nervous Diseases, and the resident house physicians,

with Dr. J. N. Mackenzie of the department of the Diseases of the Throat.

Clairvoyance and Malpractice.—The Supreme Court of Wisconsin has rendered a very important decision, says the New Haven *News*, that a clairvoyant physician is liable for failure to exercise the ordinary skill and knowledge of a physician in good standing, practising in the vicinity, and not merely to the ordinary skill and knowledge of clairvoyants. It is held by the Court that if any one holds himself out as a medical expert and accepts employment as a healer of diseases, but relies for diagnosis and remedies upon some occult influence exerted upon him, or some mental intuition received by him when in an abnormal condition, he takes the risk of the quality of accuracy of such influence or intuition.—*Boston Med. and Surg. Jornal*, May 16, 1889.

Narrow Chests and Tuberculosis.—The Prussian army surgeons have been ordered to measure the chests of recruits, especially of narrow-chested ones, every four weeks. All are to be regarded as narrow-chested, the circumference of whose chest is less than half the length of their bodies. Narrow-chested men whose chests are not widened by drill, are to be regarded as predisposed to tuberculosis, and to be discharged as soon as possible, that they may not infect healthy soldiers.—*Lancet*, May 11, 1889.

Legislation for the Prevention of Milk Infection.—The proposal which Mr. Shirley Murphy made at the Hastings Congress, that local sanitary authorities should be empowered to make regulations for the prevention of milk contamination due to eruptive diseases of the cow, will commend itself to those who only regard these affections as polluting the milk with pus and other morbid products, as well as to those who consider that they possess still larger powers of inflicting injury on the health of milk-drinkers. We have no hesitation in saying that milk thus contaminated ought not to be sold as food for man, and local authorities might well be empowered to take steps to prevent the occurrence or extension of diseases of this nature. The enforcement of regulations for securing the quarantine of cows newly arrived on a farm, the isolation of any cow thus affected, and the washing of the milker's hands between the milking of successive cows, have already been proved in different parts of the country to afford a material security against the occurrence of these maladies, and might with advantage be generally adopted. The fact that many cowkeepers enforce them in their own interest is a sufficient answer to the objection that they would interfere with business arrangements. So, again, the public have a right to be protected against possible injury through the sale of any cow suffering from eruptive disease, and especially if this animal be one of a herd whose milk is under suspicion of having caused infectious disease among its drinkers. At the present time there is no control exercised over these infectious maladies except that which is dictated by the experience of careful and conscientious cowkeepers. To demand that all should take the precautions recognized to be necessary by the few would inflict no hardship, but would even promote the cowkeepers' interests; for the loss of milk which occurs owing to the reduction in the quantity of milk supply when a cow suffers from eruptive disease is itself sufficiently important to make it desirable that every care should be taken to maintain the stock in good health.—*Lancet*, May 4, 1889.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 21 TO MAY 27, 1889.

By direction of the Acting Secretary of War, the leave of absence, on surgeon's certificate of disability, granted WILLIAM H. FORWOOD, *Major and Surgeon*, in S. O. No. 35, April 8, 1889, Department of Dakota, is extended one month on surgeon's certificate of disability.—Par. 13, *S. O. 118, A. G. O., Washington*, May 22, 1889.

MIDDLETON, PASSMORE, *Major and Surgeon.*—Will, as soon as practicable after his arrival at Fort Trumbull, Connecticut, proceed to Fort Warren, Massachusetts, and report for temporary duty until the return of the post surgeon from detached service with batteries of the Fourth Artillery ordered to Atlanta, Georgia. He will then return to his proper station (St. Francis Barracks, Florida).—Par. 2, *S. O. 113, Headquarters Division of the Atlantic, Governor's Island, New York City*, May 18, 1889.

MCELDERRY, HENRY, *Major and Surgeon.*—Is granted leave of absence for one month, to take effect upon completion of his duties as a member of the Army Medical Examining Board in New York City.—Par. 4, *S O. 44, Headquarters Division of the Atlantic, Governor's Island, New York City*, May 23, 1889.

PALZKI, J. H., *Major and Surgeon.*—Is granted leave of absence for twenty one days.—Par. 1, *S. O. 44, Headquarters Department of Arizona, Los Angeles, California*, May 18, 1889.

RAFFERTY, OGDEN, *First Lieutenant and Assistant Surgeon.*—Ordered with troops for field practice to Galveston, Texas, where troops will camp for such time as may be hereafter directed.—Par. 1, *S. O. 29, Headquarters Department of Texas, San Antonio, Texas*, May 13, 1889.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY, FOR THE TWO WEEKS ENDING MAY 25, 1889.

WHITING, ROBERT, *Passed Assistant Surgeon.*—Ordered to the Receiving-ship "Minnesota."

HARMON, G. E. H., *Surgeon.*—Detached from the Naval Academy, and ordered to the "Constellation."

LOWNDES, C. W. F., *Assistant Surgeon.*—Detached from the Naval Academy, and ordered to the "Constellation."

ARNOLD, W. F., *Assistant Surgeon.*—Detached from the "New Hampshire," and ordered to the "Pinta."

RUSH, C. W., *Passed Assistant Surgeon.*—Detached from the "Pinta," proceed home, and wait orders.

MCCLURG, W. A., *Surgeon.*—Ordered to the Bureau of Medicine and Surgery.

STITT, E. R., *Assistant Surgeon.*—Detached from the Bureau of Medicine and Surgery, and ordered to the "New Hampshire."

ECKSTEIN, H. C., *Surgeon.*—Ordered to the Marine Rendezvous, Philadelphia, Pa.

BRADLEY, M., *Medical Director.*—Detached from the Marine Rendezvous, Philadelphia, Pa., and continue on special duty at Philadelphia.

HENEBERGER, L. G., *Passed Assistant Surgeon.*—Detached

RUTH, M. L., *Surgeon.*—Granted another year's leave.

from the "Thetis," and ordered to the "Iroquois."

HESLER, F. A., *Assistant Surgeon.*—Promoted to be Passed Assistant Surgeon in the U. S. Navy.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. LIV. SATURDAY, JUNE 8, 1889. NO. 23.

ORIGINAL LECTURES.

THE ETIOLOGY AND PROPHYLAXIS OF THE TUBERCULOUS DISEASES.

Being the Address in Medicine before the Medical Society of the State of Pennsylvania, at its Thirty-seventh Annual Session, held in Pittsburg, June 4, 1889.

BY J. C. WILSON, M D,
OF PHILADELPHIA.

KNOWLEDGE, like the hard woods, is of slow growth. Auenbrugger worked seven years upon that discovery which he gave to an unheeding profession as the "Inventum Novum." Half a century later it was rescued from oblivion by Corvisart, to be extended and perfected in another quarter of a century by Piorry. Laennec had already acquired a reputation by his practice and writings, when, in 1815, he invented the stethoscope. Four years later he published his *Treatise upon Mediate Auscultation and the Diseases of the Lungs and Heart*, but almost a quarter of a century elapsed before this method of clinical investigation became popularized among medical men, and was generally taught in the schools of England and America. Jenner spent nearly twenty years in investigations and experiment before he published, in 1798, his *Enquiry* into the causes and effects of the cowpox.

Yet each of these discoveries revolutionized that department of the art of medicine which it affected, and to-day no student is entitled to receive the degree, which marks his admission to the profession, who does not know more of percussion than Auenbrugger, at least as much of the principles which underlie auscultation as Laennec, and unless he has easily acquired the essential facts of that beneficent discovery which cost Jenner twenty years of toil.

These things were in the old days. We live, if not in an era of more impatient intellectual activity and keener inquiry, at least in a time of the infinitely more rapid dissemination of information. A flash of electricity, a turn of the press, and that which happened yesterday is known all over the civilized world. But this is news, not knowledge.

Lister's memorable introductory lecture in the University of Edinburgh on "the germ theory of putrefaction, the basis of a new mode of treatment which finds its application in all departments of practice," was delivered in the autumn of 1869. It makes a little pamphlet of twenty-two pages. The time was ripe for the principles set forth in that publication, and in others which quickly followed it. Much that had gone before led up to them. We think at once of the work of Latour, of Schwann, of Pasteur. The facts were convincing. Many of the details of Lister's early methods were, it is true, unnecessary, some were faulty; but the underlying thought was right. If not a new truth, it was certainly a new application of truth.

Nearly twenty years have elapsed, and the seed sown by Lister has grown and multiplied and brought forth an abundant harvest. The surgery of to-day stands in bright contrast to the surgery of that day. The antiseptic procedure has enormously widened its scope and increased its precision. Its capacity to relieve suffering and prolong life is abundantly enlarged. The contrast is so striking that it has become customary to speak of the art of to-day as the New Surgery.

This revolution was not brought about in a day. Listerism and the operative technique which it inspired, made for a long time slow and halting progress. Prejudices were to be overcome, old habits of thought given up, the traditions abandoned, and it was only little by little, notwithstanding the readiness of inter-communication and the eagerness for new and better things which characterize the present, that the New Surgery came into being.

Koch, who had previously published a paper entitled "Investigations into the Etiology of the Traumatic Infective Diseases," announced his discovery of the tubercle bacillus and its relation to tuberculosis in March, 1882. As an example of scientific research, this work stand unequalled in the history of medicine. Had it led to no practical results, its thoroughness, the logical sequence of the various progressive stages of the investigation, its completeness, the rigid tests to which he subjected his results, make it a model for investigators in every department of biology.

Koch demands, in order to determine whether or not a given bacterium is the cause of a certain disease, the fulfilment of the following requirements:

(*a*) The special bacterium must be present in all cases of the disease.

(*b*) It must be separated from other microörganisms, and from all matter found with it in the diseased animal.

(*c*) Thus freed from all foreign matter, it must be capable, when properly introduced, of producing the disease in healthy animals.

(*d*) The bacterium must be found properly distributed in the animal in which the disease has been induced.

Not only did he devise and elaborate the technical methods by which these rules can be carried out, but he saw that every one of the conditions was absolutely fulfiled in the investigation which he had undertaken. The proof was final; the demonstration complete. The germ theory was no longer a working hypothesis; it had become, in regard to the tuberculous diseases at least, an incontrovertible fact. So admirable was Koch's account of his investigation, that Trudeau, in the Adirondacks, with but little knowledge of microscopy and very imperfect apparatus, much of which he constructed himself, was enabled by following a translation of the original report to repeat the research step by step, and verify the results by the inoculation of pure cultures of the bacillus.

The labors of Lister had not only made the discovery of special pathogenic microörganisms possible; they had made it a necessity. There were many workers in the field; the fulness of time had come. Obermeier had already in 1873 discovered the spirillum of relapsing fever. Had it not been the tubercle bacillus, some other pathogenic bacterium would have been brought to light in its causal relationship to some specific morbid process. But to Koch is due the lasting honor of having first clearly demonstrated the part played by microörganisms in the etiology of disease, and of having thus laid the foundation of the science of bacteriology.

This discovery, modestly as it had been announced by its author, was at once heralded throughout the world and received with acclamation. Klebs, Cohnheim, and others had already, without reserve, placed tuberculosis in the group of the specific infectious diseases. To have found the infecting principle itself, or at all events the carrier of the infection, seemed a boon almost beyond comprehension. Its importance appealed to the dullest attention. The mortality statistics of pulmonary consumption are, unfortunately, too familiar. To this disease alone fifteen per cent. of all deaths are to be attributed. Add to these the deaths due to tuberculosis of other organs, of the joints, of the meninges, of the peritoneum, then swell the list by the cases cut off by intercurrent diseases or accident, and the result is simply appalling. The tuberculous diseases are not endemic the world over, they are epidemic. Consider that a large proportion of the cases are chronic, progressive, inexorably disabling, and it becomes easy to realize that this group of diseases exerts an influence upon the family and upon society that nothing but the apathy begotten of hopeless familiarity renders endurable. It is easy then to understand the enthusiasm with which Koch's discovery was received. Men thought of the maxim *Causa sublata tollitur effectus.*

The cause being now found, nothing seemed easier than that it should be dealt with, and that, as a consequence, one great scourge of the human race would become preventable, if not curable. Certainly, one of the first effects was to arouse both the professions and the people from the apathy into which they had fallen in regard to these diseases. Those who had the opportunity and training proceeded to verify and extend Koch's investigations, with the result, not only of acquiring a mass of information in regard to the life-history of the bacillus itself, and a more exact knowledge of the pathology of the tuberculous diseases, but also with the acquisition of like knowledge in regard to other bacteria, and the part played by them in the pathogenesis of many other infections.

Others turned their attention without delay to therapeutic investigations, having for their object the destruction of the tubercle bacillus. It is needless to enumerate the methods of antiseptic and germicide treatment which have been the outcome of these efforts. They are fresh in your memory. Based upon insufficient knowledge of the mode of growth and development of the tubercle bacillus in the tissues, they have one after another been tried and found wanting.

These failures have afforded an apparent justification to that contingent of the profession who, preferring darkness to light, because the light has not yet flooded all the obscure places, still refuse to recognize the etiological relationship between the tubercle bacillus and tuberculosis.

Seven years have now passed. A host of workers have collected a vast array of facts which rest upon a sure basis of truth. These facts are being sorted and placed in proper relation with each other. A critical observer sees that steady progress is being made. In surgery much has been accomplished; yet the results in the diminution and cure of the visceral tuberculous diseases are not encouraging. The growth of knowledge is slow; it is not the less sure. He does not to-day seem too sanguine who looks forward to practical results of the greatest importance, if not in the cure, at least in the prevention, of pulmonary consumption.

Some broad generalizations are already possible:

1. *Tuberculosis is a specific infectious disease.*

Its exciting cause is the tubercle bacillus. Its etiology is the natural history of that parasite. The predisposing influences are those conditions, both inherited and acquired, which favor the implantation and growth of the bacillus. Its pathology is summed up in the statement of the facts which relate to the development of the bacillus in the tissues, and the effects which it produces locally and upon the organism at large. Its diagnosis no longer depends upon the anatomical character of the lesions, but upon the presence of the tubercle bacillus and upon its inoculability.

The distinction between true tubercle and pseudo-tubercle is now perfectly clear. Both these formations are composed chiefly of lymphoid corpuscles or leucocytes. They are the result of an irritative hyperplasia. But the tubercle is the result of a chronic or persistent inflammation produced by a continuously acting irritant, and spreading by the infection of neighboring parts and by the circulation. The pseudo-tubercle may be produced by the mechanical irritation of small foreign particles. It constitutes, upon the subsidence of the active process, simply a mass of fibrous tissue, which undergoes no further change, and it remains single, being without the power of giving rise to other similar structures.

The pathological unity of the tuberculous process, whatever the tissue or organ affected, however diverse the clinical manifestations, is at once established by the double test of the presence of the bacillus and the inoculability of the disease. The relationship between the most unlike lesions subjected to these tests becomes apparent. The lung packed with tubercle or riddled with cavities owes its lesions to the same cause which produces the insignificant tuberculous wart upon the hand of the pathologist who dissects it; intestinal ulceration, hyperplasia of the mesenteric glands, peritonitis, fistula in ano, may all result from the action of a common cause.

The pathological identity of processes producing the most diverse lesions in the same organ is also shown by these tests. So-called chronic catarrhal pneumonia of the apex, gray miliary tubercle, diffuse, tuberculous, cheesy infiltration in the lungs, are dissimilar manifestations of the same pathological process. Joseph Coats maintains the view that the changes of fibroid phthisis are essentially tuberculous. The "solitary tubercle" of the brain, which is usually yellow and caseated, and may be as large as a walnut, is due to the same cause as the miliary tubercles occasionally found scattered in other parts of the brain substance and so familiar in the meninges.

A large proportion of the cases called scrofulous are now known to be tuberculous. We no longer think that scrofulous individuals are especially liable to become tuberculous, for tubercle bacilli are almost constantly found in so-called scrofulous lymph-glands, bones, and joints. After a time the local tuberculosis becomes extended or generalized.

Neelsen places tuberculosis along with enteric fever, leprosy, and syphilis in his fourth group of the germ diseases—namely, the mycoses with tissue proliferation or infected ulcers.

2. *The constitutional manifestations are not directly due to the bacilli, but to toxic principles evolved during their growth and multiplication.*

The bacteriologico-chemical researches of Hoffa, Brieger, Vaughan, and others, within the past few years, have done much to clear up the relation between the special pathogenic germs of the infectious diseases and their symptomatology. They have also rendered necessary a new definition of the infectious diseases. In the words of Vaughan and Novy, "An infectious disease arises when a specific, pathogenic microörganism, having gained admittance to the body, and having found the conditions favorable, grows and multiplies, and in so doing elaborates a chemical poison which induces its characteristic effects."

Nencki obtained upon chemical analysis of tubercle bacilli, water 88.82 per cent., solids 11.18 per cent. The solids yielded 22.7 per cent. of substances soluble in alcohol and ether, which, when used experimentally upon animals, showed the presence of a tetanizing poison. This substance has not been isolated. Bonardi demonstrated in tuberculous sputum alkaloidal organic bases, which introduced into rats and guinea-pigs rapidly produced remarkable disturbances of the nervous system. This experimenter believes that these organic bases may explain the fever, sweating, disturbances of the circulation, and other general symptoms of the disease.

The wide range of intensity in the constitutional phenomena is to be explained, only in part, by the varying reaction of different individuals to morbific agencies. It is more largely due to the extent and activity of the local process. Nor can we attribute the constitutional disturbances to suppuration associated with local tuberculous processes, as in the case of the breaking down of pulmonary infiltrations, or in joint diseases; for constitutional disturbances of the same kind, and of every degree of intensity, are developed in tuberculous meningitis, tuberculous peritonitis, and in those rapidly developing cases of consumption in which the lungs are found studded with miliary tubercle without extensive caseation or suppuration. Furthermore, decided constitutional disturbances are not infrequently associated with circumscribed lesions of insignificant extent, while enormous cavities, occupying the large portion of a lobe, are not incompatible with fair nutrition and moderate health for a period of years, in cases in which, after extensive destruction, the tuberculous process, as such, has come to an end.

Finally, the frequency with which obsolescent tuberculous lesions at the apex of a lung are found in individuals dying late in life from non-tuberculous diseases, suggests the possibility that a tuberculous process, terminating in resolution, may confer upon the individual in whom it has occurred subsequent immunity from the disease. The very lesions show that such individuals have at one period of life been susceptible, while their repeated exposure to the infecting principle during subsequent periods may be fairly assumed.

3. *Tuberculosis is directly and indirectly communicable from the affected to the healthy individual.*

In other words, it is a contagious disease. Koch has demonstrated the fact that tubercle bacilli never develop or multiply outside of the body of animals. They require for their development a constant and uniform temperature of 85° to 100°; they, however, retain their vitality for an indefinite period outside of the body and under conditions extremely unfavorable for the development of other microbes.

Cadéac and Malet found that tuberculous matter dried and pulverized was, after one hundred and two days, capable of giving rise to the disease. Schill and Fischer maintain that it only loses its virulence after six months. Pietro asserts that well-dried sputum may retain its infecting power for nine or ten months if maintained at a temperature of 77° F. Bacilli with or without spores show an equal tenacity of life. The distribution of tubercle bacilli outside of the body is, however, by no means as extensive as was formerly thought. The investigations of Cornet prove conclusively that they are to be found in greatest numbers in the immediate neighborhood of affected individuals; that they are not found in the dust collected from the abodes of individuals free from consumption, nor are they to be found in the apartments occupied by consumptives who habitually and exclusively use the spit-cup.

The experimental production of tuberculous diseases by the inoculation of sputum or other substances containing tubercle bacilli is a familiar fact. When animals thus inoculated are killed in a short time, the lesions are invariably found restricted to the point of inoculation and the neighboring lymph-glands. In view of this fact, Cornet holds that the assumption that the lungs are the seat of an especial predilection for the development of the tuberculous process is absolutely untenable, the frequency of pulmonary consumption, as compared with other forms of tuberculous disease, being due to the favorable conditions presented by the respiratory organs for the implantation of the infecting material. Numerous experimenters have shown that air passing over moist surfaces is incapable of taking up tubercle bacilli; the expired air which passes over the moist surfaces of the respiratory tract, of cavities, of collections of bacilli-containing pus or muco-pus not yet expectorated, does not carry the infecting principle, and is, therefore, incapable of communicating the disease.

Nor do the expectorated matters themselves, so long as they remain moist, comply with the conditions necessary for the communication of the disease to healthy individuals except by direct contact or inoculation. When dried, however, they are capable of dissemination through the atmosphere in the form of fine dust bearing bacilli and spores, which, being inhaled by susceptible individuals, cause the disease. Desiccation is a necessary requirement for the dissemination of tubercle bacilli and spores by means of the atmosphere, and the most favorable conditions for such dissemination are found within doors. Wet weather and a moist atmosphere are unfavorable.

The fact that the disease is most frequent in crowded quarters supports the view of dissemination by means of dried sputum. Flick, in his remarkable investigations in Philadelphia, found that ninety per cent. of infected houses had an infected house joining them, while thirty-three per cent. of the infected houses showed more than one case. These facts warrant the conclusion that consumption is communicated by contact, by association, or by living in close proximity.

Flick also found that pulmonary phthisis conformed to the laws which govern the spread of contagious diseases in other respects. The grouping of the cases is the same, and the localization is influenced by the age of those predisposed to the disease. It prevails in circumscribed epidemics, which are, however, less noticeable because the disease is of long duration, whereas the ordinary contagious diseases run their course rapidly.

From this point of view, the gradual infection of several members of a household, previously free from the disease, in the course of a few months or years after the introduction of a case, becomes intelligible. So, also, married couples infect each other; and those who nurse relatives suffer from the disease, females being more liable by reason of their closer ministration. Leibermeister has observed many cases where previously healthy families became infected one after another after removal to a house formerly occupied by a consumptive patient.

It is, however, a question of the seed and the soil. A large proportion of individuals enjoy an immunity which appears to be complete; many others, while capable of infection, show a remarkable resistance to the invasion of the tuberculous process which either undergoes resolution in the region infected or makes a tardy progress interrupted by more or less prolonged periods of quiescence. Between cases of this form and the cases called *phthisis florida*, the disease manifests every degree of intensity.

These variations in the degree of susceptibility to the disease and its development serve to explain some of the objections which have been urged with more or less force against the doctrine of the contagiousness of pulmonary consumption.

Those who assert that if consumption were contagious the human race would have rapidly become extinct, overlook the fact that a considerable number of persons in every community, especially those living outdoor lives, and those who are not brought into association with consumptives in confined apartments, are not exposed; and, secondly, the fact that a certain proportion of individuals, either by reason of the resistant power of their tissues, or of the integrity of the mucous surfaces of the air-passages, or from other causes not well understood, possess a more or less complete immunity. Those who deny the contagiousness of phthisis on account of the infrequency with which medical men, nurses, and other attendants upon consumptives are said to contract it, advance an argument which rests upon insufficient grounds. A certain proportion of individuals thus brought into habitual contact with consumptives enjoy an immunity; others while susceptible doubtless escape infection by reason of the thorough ventilation and cleanliness of well-regulated wards and sick-rooms. Physicians and attendants upon those suffering from cholera or the fevers, even in hospitals in which considerable numbers of such patients are collected, do not often contract the disease, yet who will deny that according to their special modes of transmission, cholera, enteric fever, and typhus are contagious?

Another difficulty lies in the localization of the tuberculous process in its beginning, and its tardy development, the time which elapses from the infection and the manifestation of the disease being not infrequently so long that the original exposure, even when traceable, is forgotten.

The often quoted statement of Williams in regard to the exemption of nurses and attendants in the consumptive hospital at Brompton is valueless in the light of advancing knowledge. The cleanliness and ventilation of a well-ordered hospital tend to reduce the dangers of infection. The statistics of Baer and others show a mortality in prisons that is nearly four times as great as outside, the majority of cases developing not during the earlier years of imprisonment but toward its close. The fact that more than fifty per cent. of nuns in cloisters die of tuberculosis speaks for itself.

The attendants in hospitals come and go; many of them remain in the service for short periods only. The statistics of Williams are incomplete in not showing the subsequent history of the personelle upon which they are based. On the other hand, the elaborate recent statistics of Cornet prove incontestably that attendants upon the sick show as a class an enormously increased death-rate, the increase being due to tuberculosis and other infectious diseases.

4. *It is not in the ordinary sense hereditary.*

Prior to the discovery of the tubercle bacillus, the direct transmission of tuberculosis from the parent to the child was very often assumed. The frequency with which the children of consumptive parents were affected with the disease was regarded as proof of its transmission by inheritance. Even tuberculosis developing in adult life in those previously presenting every appearance of health, was assumed to be of hereditary origin, the frequent absence of tuberculosis in the parents notwithstanding, for it was assumed that hereditary tuberculosis might skip a generation or two.

Baumgarten supports the view that congenital tuberculosis may be latent, the bacilli remaining inactive in certain tissues for years, or throughout life, unless called into activity by traumatism or other influences.

The number of cases in which tubercles have been actually found in the fœtus is very small. The view that congenital tuberculosis may be due to the semen or ovum, is a pure hypothesis unsupported by proof. The opinion that it may be derived from the maternal blood by way of the placenta, rests upon a small number of positive facts. Malvoz found that microörganisms may pass the placenta only when it is diseased. Charrin found in a seven and a half months fœtus of a tuberculous woman, which died three days after birth, tuberculous lesions of the abdominal organs. Merkel discovered cheesy nodules in the palatine arch, the lymph-glands, and in the neighborhood of the hip-joint, but not in the lungs of a child of a tuberculous woman, which died directly after birth.

Should the view held by Baumgarten be proved, it will explain the presence of tubercle in the lymph-glands, bones, and marrow, and the occurrence of tuberculous meningitis, which is so common in young children. Even in very young children, the primary infection fre-

quently takes place by way of the lungs, a fact fully in accord with what is now known of the mode of contagion, the relation between the mother or nurse and the young baby affording the fullest opportunity for the communication of the disease.

The conclusion that enteric fever or scarlet fever is hereditary, would rest upon very nearly the same basis of fact upon which the doctrine of the hereditary transmission of tuberculosis has been assumed, namely, that the parents of those having the sediseases had previously suffered from them, and that, in a few rare instances, the child of an infected mother has shown the characteristic signs at birth.

In regard to the hereditary transmission of tuberculosis among the domestic animals, the statistics of the Berlin abattoir are not without interest. Among 320,000 calves, 17 were tuberculous; whereas, among 398,000 cattle, there were no less than 8000 tuberculous.

5. *A rational, scientific prophylaxis is practicable both as regards individuals and communities.*

The part played by heredity in direct distribution and propagation of the tuberculous diseases is insignificant as compared with the influence of contagion. The few children born of tuberculous parents have died promptly; those who develop the disease in infancy, die early in life; the infected children of tuberculous parents who reach adult age, are those who long suffer only from tuberculous diseases of the lymph-glands and the bones, and are not, in the absence of pulmonary lesions, likely to disseminate the infecting material.

The chief avenues of infection are the digestive and respiratory tracts. The disease is acquired by infected food, and by the inhalation of air containing tubercle bacilli and spores; other methods of invasion are infrequent and relatively unimportant.

The only sources of the infecting material are those discharges from the bodies of infected human beings and domestic animals which contain the tubercle bacilli and their spores. Of these, the chief are cow's milk used as food, and the matters expectorated by patients suffering from pulmonary phthisis, which is not likely to infect unless dried and inhaled as dust. The flesh of tuberculous cattle does not cause tuberculous diseases in those who partake of it; there is, in fact, no case on record of the communication of the disease by these means. The liability of its communication by milk is increased where there is tuberculous inflammation of the udders of the cows. It is important, therefore, that all milk used as the food of infants should be sterilized by boiling, and until used it should be kept protected from the atmosphere.

The infection by way of the intestinal tract, frequent as it is, especially in childhood, is notably less common than infection by way of the respiratory surfaces.

As Cornet has shown, the only effectual prophylaxis is in the proper care of the sputum. In this respect tuberculosis presents a strong analogy to enteric fever, of which it has been said, "that measures of prophylaxis will be efficient in proportion to the strength of our belief in the material nature of the typhoid poison, and in the possibility of destroying it or preventing its spread." It is the duty of the physician to see to it that no case of infectious disease under his care becomes a focus of contagion. In enteric fever we have long recognized a disease in which this rule can be effectively carried out by means of the disinfection of the stools. It is evident that in pulmonary phthisis we must follow the same principle of prophylaxis, the one efficient procedure being the proper disposition of the bacilli-laden expectoration.

The difficulties in the practical application of this rule lie, on the one hand, in the chronic nature of a large proportion of the cases of the disease, and, on the other, in the deeply rooted prejudices or indifference of patients in regard to the matter. Cornet has formulated the rule that a phthisical patient should never under any circumstances expectorate on the floor or in a handkerchief, but always in a spitcup; this is the one thing needful. The cup should contain a little water, and be frequently emptied into the sewer, where the contents sooner or later undergo destruction, or at all events pass beyond the reach of inhalation by man. The cup should be frequently washed with boiling water. A cup has recently been devised, and is sold in the shops in this country, which consists of a small metal frame in which a folded paper cup is set; when a quantity of sputum has accumulated, the paper may be removed and burned with its contents.

The floor should be sprinkled with water before sweeping, and the sweepings destroyed by burning. The clothing and bedding of tuberculous patients should be disinfected by prolonged boiling. The walls of apartments occupied by patients should be frequently rubbed down with bread, which may then be burned. Carpets and curtains should be shaken in the open air at a distance from houses, and exposed at intervals to the air and sun.

The acceptance and universal practice of prophylactic measures would warrant the hope that the prevalence of pulmonary consumption will diminish, as have the septic diseases following surgical operations and puerperal fever, under a rational prophylaxis.

Such a result is not only theoretically possible; its accomplishment in the course of time is, in a high degree, probable. This hope has the support of strong analogies in the records of the past; the great scourges of mankind have prevailed during more or less extended historical epochs, and then passed away. The plague which ravaged all parts of Europe during the Middle Ages, which depopulated villages and laid waste districts, which, in the form of the black death, swept over Europe in the fourteenth century, and destroped in three years twenty-five millions of inhabitants, disappeared from England with the great outbreak of 1665. Only twice during the present century has this pest shown itself in Western Europe. The disappearance of the plague was probably due to the conjoint influence of a rigorous quarantine and altered methods of living. It has been said in regard to Europe, that when the shirt came in, the plague went out.

Typhus, which devastated Europe from the fifteenth century until the end of the first quarter of the present century, of which Murchison says, "A complete history of typhus would be the history of Europe for the last three and a half centuries," has almost burnt itself out. Here and there in the seaport cities of Great Britain it still smoulders, but in the great modern campaigns of the American War and the Franco-Prussian War typhus fever was unknown. Its disappearance is unquestionably due to that prophylaxis which comes of a clear knowledge of its causes, and to the improved hygiene of modern life.

Leprosy was for thirteen centuries endemic in Great Britain; cases were still in existence on the borders of Scotland toward the close of the last century. To-day no indigenous case is to be found within the British Isles.

Smallpox was for centuries one of the greatest scourges of mankind. Scarcely a decade passed in which the disease, sweeping over great areas, did not decimate the inhabitants of one country or another. To-day we have no dread of it beyond the fear lest prolonged and complete immunity may beget neglect of the precautions which protect us.

The discovery of the tubercle bacillus has not been without practical results. Without it these generalizations were impossible. It has given us, in place of obscurity, confusion, uncertainty in regard to pulmonary consumption and the other tuberculous diseases, a positive etiology, a clear pathology, a rational therapeutics, a hopeful prophylaxis. These are great gains at the end of seven years.

But it has done more than this. It has pointed out the direction of future work, and indicated possibilities never before dreamt of. The news of Koch's discovery burst upon the world like a flash that grew faint, leaving the eyes dazzled. The knowledge which Koch has given us is like the dawn, which steadily grows brighter and brighter, until the clear day shows the perfect truth.

How shall we fitly characterize those rare men who, by sheer intellectual force, have found and given to their fellowmen new truths? By what metaphor shall we make their greatness plain? They are bright stars—suns—in the intellectual firmament, in the steady light of whose genius the work of mankind may be carried on as in the open day. I speak not of science in general, nor for the other sciences, but in medicine a century has given us five—that son of France, dead at thirty-one, whose philosophic mind conceived those generalizations which laid the foundation, not only for modern physiology, but for modern biology; that German, no longer young, to whom nothing human is without interest, busy in the affairs of men to-day as always, both in science and in politics, whose labors laid the foundation for the science of modern pathology; that Englishman, to whose clear insight mankind for nearly a century past, and for all time to come, owes the incalculable boon of deliverance from smallpox; that other Englishman, who to-day lives to see in the result of his labors the new surgery; and, lastly, him to whom we owe that discovery upon which rests the young science of bacteriology—they are called—names never to be forgotten!—Bichat, Virchow, Jenner, Lister, Koch.

LAPAROTOMY FOR PERFORATING TYPHOID ULCER.

BY N. SENN, M.D., PH.D.,
OF MILWAUKEE, WIS.,
ATTENDING SURGEON TO MILWAUKEE HOSPITAL, PROFESSOR OF PRINCIPLES OF SURGERY AND SURGICAL PATHOLOGY, RUSH MEDICAL COLLEGE, CHICAGO, ILL.

THE following case is reported as an addition to the as yet meagre statistics of laparotomy for perforating typhoid ulcer.

C. H., male, aged twenty-two, admitted into Milwaukee Hospital March 31, 1889.

History.—Patient has been under treatment for the past three weeks for extensive bronchitis. He was never confined to his bed, but came to my office two or three times during the above period. His temperature was never over 101° F. There was complete loss of appetite, but no symptoms pointing to intestinal disturbance. March 31st, visited at his home. Three days ago he had an acute attack of pain in the left iliac region, followed immediately by vomiting, which has since then continued and has latterly become stercoraceous. During this time there has been absolute constipation notwithstanding repeated doses of castor-oil, administered by his friends, which only aggravated his symptoms. Abdomen was found very tense, tympanitic throughout except over the left iliac region, where dulness was present and exceedingly tender on pressure. Liver dulness displaced upward. Patient collapsed, pale, and pulse 140. Stimulants per rectum ordered.

Probable diagnosis, volvulus with obstruction.

March 31. He was removed to the Milwaukee Hospital for laparotomy. Vomiting still continues, and in addition to the symptoms of yesterday a cracked-pot resonance, on percussion to the right of the area of dulness. Considerable fecal-colored fluid removed from stomach by siphon irrigation. Stomach irrigated with one-third per cent. solution of salicylic acid. Two ounces of brandy administered by rectal injection and one-one-hundred-and-twentieth grain of sulphate of atropia hypodermically. Chloroform as anæsthetic on account of the bronchitis. Temperature of operating room 90° F. Abdomen opened by a median incision, four inches in length, extending downward from one inch below the umbilicus (subsequently enlarged upward four inches). The livid, overdistended intestines immediately bulged into the incision at points covered with plastic lymph. Manual exploration of abdomen with negative result. Evisceration necessary to determine the seat of obstruction, during which the bowels were caught in and kept covered by warm aseptic compresses. A number of loops of the upper portion of the ileum were found enlarged twice the size of the remaining portion of distended intestine, rotated on the mesenteric axis one complete turn from left to right. Volvulus corrected.

Below this point the intestine was found overdistended, and while withdrawing for examination, fluid feces escaped through the abdominal incision with a sudden gush, coming from the left iliac fossa and in quantity about one pint. Intestinal loops showed large and thick patches of plastic lymph, especially the coils removed from the pelvis. A few minutes were spent in searching for the perforation, during which preparations were made for hydrogen gas insufflation for the purpose of locating the perforation. A leakage was accidentally discovered taking place through a small perforation in the centre of a large membranous patch at a point six inches above the ileo-cæcal valve. The opening was located on the convex side of the bowel nearly opposite the mesenteric attachment, surrounded by

a gangrenous patch, oval in shape and irregular in outline, one-half inch in length and one-quarter inch in width. The plastic lymph was removed as completely as possible, the gangrenous portion turned inward and completely buried by eight interrupted Lembert sutures, embracing the peritoneum, muscular, and submucous coats, a procedure which narrowed the lumen of the bowel to one-half its normal size.

Examination of the intestine for some distance above and below as far as the ileo-cæcal valve revealed no additional perforations.

During the whole period that the abdominal cavity had been open, two irrigators, one on either side, were employed for flushing the abdominal cavity with a one-third of one per cent. solution of salicylic acid at the temperature of the body—the glass tips being placed alternately in the lowest part of the pelvis and lumbar regions.

On attempting to replace the intestines within the abdomen, it was found to be impossible on account of the great distention; consequently that portion involved in the volvulus was sought for and an incision made in its centre on the convex side, one inch in length, and a considerable quantity of fluid feces, but no gas, escaped. The incision only succeeded in emptying a limited portion of bowel, as all peristaltic action was completely suspended. Three feet of intestine, on either side of the incision, were completely emptied by the pouring-out process, viz., seizing the highest loop and raising it, thus pouring contents from loop to loop until the incision was reached. The same process was repeated on the other side of the incision. The bowels were now cleansed by irrigation, incision closed by interrupted Lembert sutures, after which reduction was easily accomplished.

A large curved glass drain was introduced into the most dependent point of the abdominal cavity, and the external incision closed in the usual manner with the addition of three tension sutures, extending down to, but not including, the peritoneum. The fluid remaining in the abdominal cavity was now made to escape through the drainage tube by turning the patient on his face. Antiseptic dressing applied and retained by strips of adhesive plaster embracing two-thirds of the body, covered with common cotton and bandage. Glass drain plugged with antiseptic cotton and instructions given to remove the fluid by aspiration from the drainage-tube every hour, and to wash out the tube with a physiological salt solution. Duration of operation one hour. Pulse about 160 and distinctly perceptible at the wrist.

After-treatment.—Foot of bed elevated; externally dry heat was applied, and stimulation by rectal injections of brandy. Vomiting ceased. Two evacuations of the bowels. Three hours after operation complete collapse supervened and death seven hours later.

Post-mortem twelve hours after death. Diffuse septic peritonitis. The pathological conditions indicated that the inflammation commenced in the left iliac region at a point where the perforation had taken place. The loops of intestine which constituted the volvulus were only half as large in circumference as at the time of the operation. The remaining portions of the small intestine considerably dilated and intensely congested, with here and there patches of plastic exudation. The sutures in both places where the intestine had been sewed were buried underneath a delicate layer of plastic lymph which formed quite a firm adhesion between the coaptated serous surfaces.

A few ounces of bloody serum in the cavity of the pelvis.

Liver and spleen enlarged, parenchyma softened.

On slitting the ileum open from the ileo-cæcal region upward three elliptical ulcers were found below the point of perforation. Above the perforation no gross textural changes. Mucous membrane in lower portion of ileum in a state of catarrhal inflammation.

REMARKS.—The post-mortem appearances in this case leave no doubt that notwithstanding the mildness of the febrile attack the patient suffered from genuine typhoid fever. The bronchitis was such a conspicuous symptom during life that the presence of any serious pathological changes in the intestines was not even suspected. Perforation of one of the typhoid ulcers occurred at the end of the third week of the illness and gave rise apparently at first to circumscribed peritonitis, which limited the fecal extravasation but did not prevent the extension of the septic inflammation. The symptoms of obstruction were undoubtedly due to the presence of the volvulus and to the suspension of peristalsis in that portion of the intestinal canal concerned in the septic inflammation. The volvulus was caused, without doubt, by the distention of the intestines and the arrest of peristaltic action, conditions produced by the septic peritonitis.

So far, the operative treatment of perforating typhoid ulcer has proved successful only in the case reported by Mikulicz, and in this instance there appears to exist no convincing proof of the correctness of the diagnosis in reference to the etiology of the ulcer.

This case illustrates forcibly the necessity of resorting to direct treatment of the perforation as soon as its presence can be diagnosticated, with a view of preventing the diffusion of the septic infection. If the operation is postponed until a general septic peritonitis has had time to develop, the prospects for a favorable result are almost *nil*, and under such circumstances the execution of the operation is attended by the greatest difficulties on account of the distended and paretic conditions of the intestines.

As a perforating typhoid ulcer must almost of necessity lead to a speedy fatal termination, abdominal section, suturing of the perforation, and disinfection of the abdominal cavity present themselves as urgent, and the only rational indications in the treatment of such cases.

LARYNGEAL VERTIGO.[1]

BY S. T. ARMSTRONG, M.D., PH.D.,
PASSED ASSISTANT SURGEON, U. S. MARINE-HOSPITAL SERVICE.

ATTENTION was first directed to this peculiar laryngeal neurosis by Prof. Charcot, in a communication that he made to the Société de Biologie of Paris (*Comptes Rend. Soc. de Biol.*, Paris, 1876), in which were reported two cases of an undescribed neurosis to which he applied the term "laryngeal vertigo."

CASE I. was in a gouty male, aged fifty-five years, who, after a slight cough, lost consciousness without presenting the least trace of convulsion. The patient had never presented any symptom of epilepsy.

CASE II., a male, aged fifty-four years, not an epileptic, for a year had occasional attacks that originated in a feeling of titillation below the larynx, followed by a short, dry cough that culminated in loss of consciousness. The attack was of short duration, and though the face became turgid, and there were some slight convulsive movements of the head and arms, yet he never bit his tongue, nor voided his urine, nor was in the slightest way mentally confused at the end of an attack. The latter were increasing in frequency, as many as five or six a day occurring, and they might commence while he was walking in the street. An attack would not, however, occur whenever he coughed. In this case the patient experienced an indefinable vertiginous sensation, but it never resulted in falling. Examination of his throat showed a slight, granular pharyngitis; he had suffered from chronic bronchitis and emphysema for a long time. Nitrate of silver was applied to the pharynx, and bromide of potassium given internally. The patient recovered; possibly, Charcot said, by using the medicine, possibly by other causes.

Subsequently Charcot reported (*Progrès Médical*, 1879, p. 317) other cases:

CASE III.—A male, aged forty years, who suffered from asthmatic attacks. During one of these he felt a painful, burning titillation below the larynx, followed by a short cough that resulted in unconsciousness; during this he had clonic movements of the arm. An examination revealed slight roughness of the mucous membrane of the larynx.

CASE IV.—A male, aged forty-five years, who had bronchitis the previous year, followed by a permanent feeling of heat and titillation in the larynx. He would have a slight cough, culminating in vertigo. The larynx was normal.

Charcot considered that the term laryngeal vertigo might be applied to an irritation of the centripetal laryngeal nerve, just as the title Ménière's vertigo is connected with an affection of the auditory nerve in the labyrinth:

CASE V.—Gasquet (*Practitioner*, August, 1878) reported a case in a male, aged seventy years, who caught a severe cold, and subsequently had an irritation of the larynx, causing violent spasms of coughing, with urgent dyspnœa. Eventually the coughing was followed by loss of consciousness for two or three minutes; on recovering consciousness he felt giddy and confused. Under treatment the paroxysms ceased.

CASE VI.—Krishaber (*Ann. des Malad. de l' Oreille et du Larynx*, 1882, p. 12) reports a case in a male, aged thirty-two years. He uses the term "ictus larynge," and considers it due not only to spasm of the glottis, but also to arrest of the diaphragm.

CASE VII.—Landon Carter Gray (*Amer. Journal of Neurol. and Psych.*, 1882, p. 588) reported a case in a male, aged fifty-five years, in whom the same symptoms were presented as in the foregoing case. In this case, however, the patient had been wounded by a bullet, in 1863, and during his convalescence he had epileptiform seizures, with loss of consciousness, for two months. This case presented a decided neurotic history. Gray proposed the name laryngeal epilepsy.

CASES VIII. and IX.—Lefferts (*Arch. of Laryngol.*, 1883, p. 165) reported two cases in comparatively young men; in each a spontaneous tickling sensation in the larynx caused a cough that resulted in a temporary brief unconsciousness. The larynx was normal in each case, and there was no history of epilepsy.

CASE X.—P. McBride (*Edinb. Med. Rev.*, 1884, p. 790) reported a case under the title, "Rare Form of Laryngeal Neurosis." A male, aged thirty-five years, had difficulty in breathing, two weeks after having swallowed a fish-bone. He would have a short cough, causing swimming in the head and dizziness. He never lost consciousness nor presented epileptiform symptoms, and McBride considered that the paroxysm was due to spasm of the glottis.

CASE XI.—Russel (*Birmingham Med. Rev.*, 1884, p. 71) reported a case in a male, aged fifty years, who suffered from catarrhal pneumonia for fourteen years. The tickling in the larynx culminated in cough and unconsciousness. No epileptiform symptoms.

Massei (*Giorn. Internaz. de Scien. Med.*, Naples, 1884, p. 192) reports three cases:

CASE XII.—A male, aged forty-five years, who had suffered from chronic bronchial catarrh, with acute exacerbations, who had one attack of laryngeal vertigo.

CASE XIII.—A male, aged fifty years, suffering from chronic follicular pharyngitis. He had repeated attacks of syncope consequent upon moderate coughing. He had diffuse catarrh of the larynx and trachea.

CASE XIV.—A male, aged fifty-six years, had suffered from vertigo from his thirty-first to his forty-second year. He would have asthma, with cough culminating in vertigo, sometimes four attacks a day. Laryngoscopic examination revealed hyperæmia of vocal cords and trachea. He was diabetic.

None of these cases had epileptiform symptoms or antecedents; nevertheless, Massei compares laryngeal vertigo to epilepsy, and attributes its origin to vagus irritation: "The irritation of the vagus disturbs, by alteration of the function of the heart, the circulation in the brain, and thus causes a change in the relation between the arterial and venous tension and the condition of the cerebro-spinal fluid that is sufficient to cause vertigo and epileptic attacks."

F. I. Knight (*Trans. Amer. Laryng. Assoc.*, 1886) published a very interesting and comprehensive paper on this subject, reporting two cases:

CASE XV.—A male, aged forty-two years, suffering from bronchitis for a year, who had an attack of laryngeal vertigo after being subjected to severe mental strain for some time. There was no evidence of spasm of the glottis, nor of convulsive movements.

CASE XVI.—A female, aged forty-seven years, who had granular pharyngitis for ten years. She lost consciousness only once after coughing. Both of these cases recovered under treatment.

[1] Read before the Section in Laryngology and Rhinology, New York Academy of Medicine.

CASE XVII.—C. W. Chamberlain (*Proc. Conn. Med. Soc.*, 1882, p. 47) reports the case of a male, aged thirty-eight years, who had been garroted. After the acute inflammatory symptoms had subsided, he was seized, after dining, with inability to breathe. He had a series of catching respirations that resulted in syncope. These attacks would occur after eating or when very much fatigued. He never had epileptiform symptoms. Cured by strychnine.

CASE XVIII.—E. Weill (*Rev. Mens. de Laryng.*, October, 1888) reports the case of a vigorous male, aged forty-five years, who had suffered from asthma for eight years. During the attacks of asthma he is subject to attacks of laryngeal vertigo.

CASES XIX. and XX.—G. Thermes (*Journ. de Méd. du Paris*, 1887, p. 936) reports two cases of whooping-cough in males, aged sixty-four and sixty-seven years, respectively. Toward the termination of the disease, fits of coughing would occur that would cause oscillatory sensations, with cloudiness of vision and temporary unconsciousness.

To these cases, that cover the literature of the subject, as far as ascertainable, is to be added the following:

CASE XXI.—G. W. C., male, married, aged forty-four years, of vigorous physique, though inclined to *embonpoint*, consulted me in 1888, for his throat. He stated that he had suffered from attacks of spasmodic asthma since childhood, except during a voyage to South America, and during four years' service in the Civil War. At the close of the war he engaged in railroading, and four weeks after confinement in an office his asthmatic trouble recommenced. His business necessitated his residence in Philadelphia, Baltimore, Cleveland, Chicago, St. Paul, and New York, and notwithstanding this variety in his climatic environment, the trouble remained about the same, although in recent years his discomfort from this has greatly diminished. If he spends his summers in the country, he is a sufferer from hay-fever.

In 1875 he was garroted, his throat and chest being severely beaten. His injuries necessitated his confinement in the house but for a few days, though for some time subsequently he felt a soreness in his throat.

In 1876, while lying on a lounge, he suddenly felt a catching in his throat, objects revolved around him, and he fell forward unconscious, remaining so for about a minute; his face was purplish-red, and, on recovering consciousness, he felt nauseated. Since the first attack, he would at various times feel a sensation of tickling in his throat, that would result in a few sharp, short coughs, culminating in unconsciousness. This latter condition would endure for a variable period, from a few seconds to a minute. On recovering consciousness he would, as in all the reported cases, resume a conversation or any other matter with which he had been engaged at the commencement of an attack. He never had any epileptiform symptoms, and his family history is unexceptionable.

He has noticed that the attacks would never occur in the open air, always in closed or heated rooms. Nervous excitement or fatigue were inciting causes. Though occasionally he has suffered from dyspepsia, the attacks were not associated with this trouble.

He has consulted specialists in all the cities in which he has resided, and the consensus of opinion is that the garroting produced a laryngeal trouble that caused the cough. No particular importance was attached to the syncope, though to him it has been the most alarming symptom.

His inspiratory murmur was stridulous, and sonorous and sibilant râles are detected over each lung. The chest is well developed, measuring thirty-eight and a half inches in circumference. An examination of the larynx reveals congestion of the arytenoids and false vocal cords, occasionally resulting in an acute laryngitis. The rima glottidis is of normal size, and there seems to be proper nerve stimulation to the vocal cords.

With the intention of relieving the asthmatic condition, potassium iodide was administered, but no relief followed this medication. He was then given doses of sodium bromide at night, with syrup of hydriodic acid during the day. This treatment caused immediate diminution in the frequency and irritability of the larynx, and he has not now suffered from an attack for some time.

Sphygmographic tracings of the pulse during an effort at forced expiration, while the glottis is closed, show but little divergence from the same experiment in a healthy man. No dizziness was felt during this effort at forced expiration, which was kept up for thirty seconds. Several repetitions of this experiment produced no different result. Rapid inspiration, persisted in for some time, produced nothing but physical fatigue; and, as the patient stated, during an asthmatic attack he has kept up rapid respiration for twenty-four hours without unconsciousness resulting. If he coughs protractedly, cloudiness of vision occurs, but no unconsciousness. A differentiation between this cloudiness and the obscuration that precedes the unconsciousness of a vertiginous attack, is that *muscæ volitantes* occur in the latter.

From the brief *résumé* of the reported cases it may be inferred that there is a diversity of opinion as to the exact nature of the disease.

Several excellent authorities consider it a laryngeal epilepsy, but so many features are lacking in a resemblance to even a mild form of *petit mal* that this, it seems, is an inappropriate nomenclature. As Knight (*op. cit.*) says: "Loss of consciousness does not compel us to consider a case epileptic, for asphyxia and syncope may produce temporary unconsciousness." Furthermore, in the case of Sommerbrodt (*Berl. klin. Woch.*, Sept. 25, 1876), a polypus on the left vocal cord produced clonic convulsions with unconsciousness, foaming at the mouth, biting of the tongue, with subsequent paresis of the left arm and leg. In this case there were decided epileptic symptoms, but none of the reported cases of laryngeal vertigo resembles it, save in loss of consciousness. Landon Carter Gray (*op. cit.*) fortifies the applicability of the term laryngeal epilepsy by comparing it with the cough in cases of posterior spinal sclerosis; in these cases, while the same fun-

damental pathogenesis may exist, yet the attacks are of longer duration, and a post-mortem examination reveals degeneration of the pneumogastric. As all the cases of laryngeal vertigo are reported improved by treatment, it is improbable that any gross lesion of that nerve occurs in the disease.

Gasquet (*op. cit.*) considers that a reasonable explanation of the phenomena is Woakes's theory ("Etiology and Treatment of Occipital Headache," *Practitioner*, 1878, p. 263) of the transmission of impressions to the inferior cervical ganglion; this causes vaso-dilatation of the vertebral artery and its labyrinthine branch, with corresponding pressure on the endolymph or fluid in the semicircular canals; hence the interference with the equilibrating apparatus. While it is impossible to contradict this theory, it seems unnecessarily elaborate, especially when the nervous connections are considered.

Thermes (*op. cit.*) explains the phenomena by an afferent impulse from the superior laryngeal to the pneumogastric, thence to the respiratory centre in the medulla; these cause efferent impulses, culminating in cough, etc.

If vertigo is a sense of defective equilibrium, associated with revolving of surrounding objects and a feeling of cerebral oppression, the reported cases do not evidence the existence of these symptoms, and the term is a misnomer applied to this laryngeal neurosis. The fact that there is an aural, an ocular, or a stomachic neurosis resulting in vertigo, does not necessitate the existence of a laryngeal reflex.

Weir Mitchell ("Vertigo," *Pepper's System of Medicine*, vol. v. p. 419) refers to the close relation of the pneumogastric centre of the cerebellum to the centre of equilibration as demonstrated by the gastric symptoms in vertigo. Working from this fact we must conclude that the impulse from the superior laryngeal nerve must cause afferent and efferent impulses in the pneumogastric; the former to the cerebellum, causing interference with the equilibrating centres (syncope), and the latter to the stomach (nausea).

Weber (*Müller's Archiv*, 1851) gives a theory of vertigo due to circulatory disturbance: "The pressure exercised at the summit of the venous cone results in a considerable reflex in the veins that is not prevented by the valves, the blood constantly arriving and finding no outlet. Hence a stasis results, with distention of the thoracic veins, followed by injection of the eyes, redness of the face, abolition of the cerebral circulation, with at last suppression of the functions of the brain (vertigo and also apoplexy), of the peduncles, and of the corpora quadrigemina." McBride (*op. cit.*) accepts this theory, and quotes in confirmation of it the analgesia produced by rapid breathing. The comparison seems defective in that the latter result is a consequence of oxygen intoxication, while the former is, in part, a carbonic acid intoxication. It is believed, furthermore, that a refutation of this theory is demonstrated by the failure to cause vertigo in the case herewith reported by the intense pressure on the venous system attained in the effort at forced expiration with a closed glottis, even when persisted in for thirty seconds; also by the failure of comparatively long attacks of coughing to cause unconsciousness.

All authorities agree that the inception of the attack is due to a short, sharp cough. It is, therefore, improbable that that this causes toxic venous stasis, where a prolonged cough will not. So the circulatory theory must be abandoned for the neurotic.

As the entire phenomena rest upon the occurrence of loss of consciousness, the laryngeal symptoms being either negative or unimportant, and as this loss of consciousness is as sudden as that occurring in ordinary syncope (though of much shorter duration), the term *laryngeal syncope* might be adopted for cases presenting the symptoms herein described, because such a term would neither do violence to the probable etiology of the affection nor to the exactness of our nomenclature.

The treatment seems based on local counter-irritants in cases presenting laryngeal symptoms, and the bromides internally, although in several cases strychnine has proved advantageous.

NEW YORK, March 26, 1889.

MEDICAL PROGRESS.

Antisepsis as Practised by M. Trelat.—MR. ERNEST HART (*British Med. Journal*, May 25, 1889), writing of "Medical Paris of To-day," gives the following account of the antiseptic method as used by Professor Trélat:

The special precautions which he borrows from Lister and from French antecedents are drainage and dressings with antiseptic gauze or other substances; repeated washings with antiseptic solutions are also frequently employed in his clinique with good results. Whenever it is possible, M. Trélat has suppressed drainage of wounds, even for extensive wounds, or for amputation, or removal of tumors. Where perfect apposition is possible he secures it by maintaining it by superficial and deep sutures, and leaving no drain in the wound. After a successful course of operations for more than two years, he has obtained absolute confidence in this method of proceeding, which may be described as the British method following on the indications of Liston, Ferguson, and Lister.

In all his operations he employs, after thorough washing with soap both of the hands of the operator and of the field of operation, a solution of biniodide of mercury, containing in each quart of water 20 grammes of alcohol, 0.1 gramme of iodide of mercury, and 0.03 gramme of iodide of potassium; without the addition of iodide of potassium the iodide of mercury is insoluble in this preparation. By the addition of the iodide of potassium the iodide of mercury is somewhat decomposed; it is

transformed into an iodurated iodide of mercury. Nevertheless, prolonged experience during the last three years, which had in the first instance demonstrated the insufficiency of a solution of 5 centigrammes, has established in his practice the perfect efficacy of the solution employed. That solution has, he considers, the great advantage of being at least as efficacious as the solution of bichloride of mercury 1 per 1000, and infinitely less irritating to the hands of the operator and to the tissues and organs of the patient, especially in the neighborhood of the anus, vagina, etc.

After operation, terminating with bandages, washing, complete suture, and without drainage, he employs very simple dressings, most frequently iodoform gauze, which he replaces frequently with salol gauze; above this a layer of thoroughly aseptic anhydrous cotton-wool, externally a layer of ordinary cotton-wool, extending far beyond the wound. The whole is kept in place by many turns of the bandage, arranged so as to obtain regular and pretty firm compression of the seat of operation. When necessary he adds for some hours an India-rubber bandage, promptly replaced by an ordinary linen bandage. This dressing is undone at the end of five or six days and the sutures removed; the new dressing is not taken off for ten or twelve days later, when the cure is complete.

Lanolin in Blenorrhagia.—DR. STERN, according to the *Revue Gén. de Clin. et de Thér.*, May 2, 1889, has used injections of lanolin with great success in a number of cases of blenorrhagia. The discharges disappeared rapidly. After a continuation of this treatment for eight days, Dr. Stern uses astringent injections, and finally a one and a half per cent. solution of resorcin.

The formulæ preferred by him are as follows;

I.—*Simple Lanolin Injection.*

℞.—Lanolin . . . . 25 parts.
Oil of sweet almonds . . 75 " —M.

II.—*Antiseptic Injection.*

℞.—Salicylic acid . . . 4 grains.
Lanolin . . . . ℥vjss.
Oil of sweet almonds . . f ℥ijss.—M.

III.—*Astringent Injection.*

℞.—Sulphate of zinc . . . ¼ grain.
Distilled water . . . f ℥jss.
Lanolin . . . . ℥vj.
Oil of sweet almonds . . f ℥ijss.—M.

A Cure for Dandruff.—DR. A. J. HARRISON, of Bristol, recommends the following salve for dandruff:

Caustic potash . . . . 8 grains.
Phenic acid . . . . 24 grains.
Lanolin } . . . . āā ℥jv.—M.
Cocoanut oil }

This preparation should be rubbed into the scalp morning and evening. Complete cure is usually effected in one to three months.—*Le Progrès Méd.*, April 20, 1889.

Treatment of Diaphragmatic Hernia.—PROF. POSTEMPSKI, of Bologna, relates the case of a patient who had been stabbed, four months before coming under notice, in the sixth interspace on the left side. The wound healed in eight or ten days, and he went back to his work. On making an effort, however, such as lifting a heavy weight, he suffered from painful sensations referable to the heart and intestines. The heart was displaced, there was tympanitic resonance in the left chest above the nipple, intestinal occlusion, stercoraceous vomiting, and dyspnœa. He died soon after admission to the Consolazione Hospital. On *post-mortem* examination, a wound two centimetres long was found in the diaphragm, and the transverse and descending colon with almost the whole of the omentum were herniated into the thorax.

This case led Prof. Postempski to devise an operation by which he thinks it possible to cure such a condition. Having convinced himself by experiments on the dead body that it is not possible for the surgeon to reach the diaphragm from the abdomen, he proposes that an opening should be made in the chest-wall as in thoraco-plasty, one or two ribs being divided in two places if necessary, and the wound in the diaphragm sutured, the edges being first freshened if need be. Section of the ribs is not required in the lower spaces. On March 4th of the present year he had an opportunity of trying this operation on the living subject. A boy, aged fourteen, received a stab two centimetres long in the eleventh interspace on the left side in the posterior axillary line. The omentum protruded from the wound to a length of five or six centimetres. Prof. Postempski enlarged the wound by twelve centimetres, and forced the eleventh and twelfth ribs widely apart, bringing into view a large part of the vault of the diaphragm, in which a wound one and a half centimetre long was seen. The protruding omentum was tied and cut away, the stump being pushed back into the abdomen. The edges of the diaphragmatic wound were then brought together with silk sutures passed through the whole thickness of the muscle. The pleural cavity, which contained clots of blood, was washed out, and the wound in the chest-wall was closed with deep sutures passing through the parietal pleura. No drainage-tube was used. On opening the chest, the air had rushed in and caused pneumothorax, but no serious consequence followed this. After the wound was closed, emphysema of the whole left side of the chest up to the neck came on. In less than a fortnight both pneumothorax and emphysema had disappeared; the wound healed by first intention, and the patient was presented to the Roman Academy of Medicine three weeks after the operation. On April 1st he left the hospital quite well, except for slight pleuritic thickening round the wound.—*The British Med. Journal*, May 4, 1889.

Iron for Children.—Although the value of iron tonics for children is well recognized, yet the usual formulæ in which they are prescribed are most unpleasant and difficult to administer. The following are quoted from the *Revue Gén. de Clin. et de Thér.*, May 9, 1889, and will be found both pleasant to take and effective:

I. Effervescent ferruginated lemonade. The two mixtures are added to each other at the moment of drinking:

Mixture A.

℞.—Citrate of iron . . . . gr. ix.
Citric acid . . . . . gr. xij.
Water . . . . . f ℥ij.—M.

Mixture B.

Bicarbonate of potash	gr. xij.
Syrup of lemon	℥ijss.
Water	f℥jss.—M.

The above is sufficient for two doses.

II. Pills of pepsin and iron. Tanner prescribes two of the following pills for children three years of age:

℞.—Reduced iron	19 grains.
Phosphate of zinc	9 "
Pepsin	19 "
Glycerine	q.s.

Make into twenty pills.

III. The following is also always easily administered and greatly liked by the little ones:

℞.—Hydrated peroxide of iron	℥j.
Confection of orange } Confection of opium }	āā ℥v.—M.

Dose, from one-half to one coffeespoonful, according to age. The above is highly recommended by Dr. Ellis.

The Toxic Action of Cocaine.—Regarding the action of cocaine, DR. WÖLFLER (*Deutsche med. Woch.*, May 9, 1889) has found that it is far more toxic when used in operations on the head or face than when used on other parts of the body. In operations on the extremities sixteen minims of a five per cent. solution may be injected without any unpleasant symptoms arising, while in operations on the face, head, and even the neck, toxic symptoms will be observed if more than one-third of a grain is used.

Splenectomy.—PROF. D'ANTONA related a case at the Surgical Congress of Bologna, in which he had removed the spleen on account of chronic fever caused by a specific bacterium. The patient, a boy, aged three and a half years, suffered from pleurisy, with effusion on the left side, in March, 1887; a few weeks later he had gastro-intestinal catarrh, with high temperature at night, and swelling in the region of the spleen. On the thirteenth day there was resolution of the fever, but the spleen continued to enlarge. Arsenic, quinine, and other antimalarial remedies were tried in vain. The fever returned in a short time, and antipyretics were powerless to reduce it. There were occasional sudden remissions, to the extent of four or five degrees. Meanwhile the spleen became larger and larger, but the child could run about the house, and had a most voracious appetite. In June, 1888, when Dr. D'Antona saw the little patient, the belly was large, the body emaciated, the intelligence bright; he suspected the existence "of some infection *sui generis* situated in the spleen and invading the organism from time to time." On August 13th, splenectomy was performed. The temperature fell to the normal point on the day of the operation, and though there was a slight rise on the following day, the fever ceased entirely on the fifth day. This temporary improvement was followed by gastro-intestinal catarrh, purulent otitis, and afterward diffuse bronchitis. These complications disappeared, and the child seemed to be completely cured. About five months later the boy's father, who was a medical man, had two patients with cerebro-spinal meningitis under his care: the boy contracted the disease and died, but there was no *post-mortem* examination.

Dr. D'Antona presented the extirpated spleen, which weighed one kilogramme three grammes, being about one-tenth the child's total weight. The blood obtained from the spleen was very pale, the white corpuscles not increased, the red discolored. Cultures made in agar-agar broth, and serum gave no result for eight days, then a bacillus resembling the microbe of typhoid was discovered, which Dr. Caselli believes to have been the cause of the disease. In grew with difficulty in agar-agar, better in gelatine; but unlike the typhoid bacillus, it did not grow on potato. Inoculation experiments have so far proved fruitless.

DR. CECI described the result of splenectomy in a girl on whom he performed that operation three years previously. At the age of eighteen menstruation had not yet begun. Twenty days before the operation, great enlargement of the thyroid took place; this disappeared in two months, but the patient remained in a marasmic condition. Some months later, remarkable improvement took place, and she gained considerably in weight. Coincidently with this improvement, hypertrophy of the tonsils took place to such a degree as to threaten suffocation. He removed one tonsil, a fortnight after which the goitre disappeared entirely. The patient gained further in weight, and has since remained in perfect health. Dr. Ceci thinks that the enlargement of the tonsils was vicarious, these organs having in some way taken the place of the spleen which had been excised.—*The British Med. Journal*, May 4, 1889.

Psoriasis of the Head.—As a most excellent remedy for psoriasis capitis DR. E. STERN, in the *Correspondenzblatt für Schweizer Aerzte*, May 11, 1889, recommends the following:

℞.—White precipitate of mercury	10 parts.
Green soap	40 "
Anhydrate of lanolin	50 " —M.

The disease will completely disappear inside of a week leaving the skin smooth and white. The application of lanolin cream and daily washing will soon restore the normal functions of the skin.

Iodoform in Inflammation of the Joints.—DR. V. MOSETIG-MOORHOF, who is in charge of the Imperial Hospital of Wieden, Austria, has observed most excellent effects following the hypodermatic use of ethereal solution of iodoform in cases of articular inflammation, especially of a fungus type. The injections frequently cured cases in which otherwise excision would have been necessary. Dr. v. Mosetig-Moorhof tried the effects of other antiseptics used similarly, but their action was very unsatisfactory.—*Centralblatt für Chirurgie*, May 4, 1889.

The Vitality of the Typhoid and Cholera Bacillus.—By a series of experiments DR. J. UFFELMANN has demonstrated that the bacillus of typhoid fever has a most tenacious vitality, and that it will not only live but increase in decomposing fecal masses for fully four months. At a temperature of 50° F. they will gradually decrease in number, but will increase at a temperature of 63° F. Contrary to this, it was found that the cholera bacillus was of a "most delicate constitution," and at longest it only lived four days in fecal masses, but usually died much sooner. The latter bacillus seemed to live longer

in water than in feces.—*Prager med. Wochenschrift*, April 17, 1889.

Treatment of Fractured Patella by Wiring the Fragments.—DR. CECI, at the Surgical Congress of Bologna, reported eleven cases in which he had treated fractures of the patella by subcutaneous wiring with buried sutures. The patients were for the most part between fifty and seventy-eight years of age. In nearly all the cases the fracture was simple and transverse, but in one there was comminution of the lower fragment, and in another, a man, aged sixty-nine, the bone had been broken a second time two months after the first accident. Dr. Ceci uses silver sutures. All the cases had done well, hæmatoma and non-infective arthritis having occurred only once.—*The British Med. Journal*, May 4, 1889.

A Modification of Dr. Jeffries' Bread for Diabetics.—Dr. JOHN A. JEFFRIES published in the *Boston Med. and Surg. Journal* of January 24, 1889, the following formula for a new diabetic bread: One cup of graham flour; one cup of best bran previously scalded with one cup of boiling water; two eggs; German yeast or baking powder; salt to taste; one cup of milk or water. To be mixed with a spoon. Such a bread contains 17.72 per cent. of starch, the equivalent of 19.68 per cent. sugar.

Dr. James Tyson, in the *University Medical Magazine* for June, 1889, writes as follows:

"Happening to have at the time a case of diabetes, where the sugar was eliminated by a selected diabetic diet from which bread was excluded, it occurred to me to make a trial of this modified bread. Accordingly some was made after this formula; at the end of one week the urine was found to contain between one-half per cent. and one per cent. of sugar; it then occurred to me to modify the formula by substituting the gluten flour of the Health Food Company of New York for the graham flour, mixing it with bran as before. At the end of another week the urine was found to contain about one-quarter of one per cent. of sugar; the patient was then taken off of all bread, and at the end of another week sugar had disappeared from the urine, showing that this combination, as was to be expected, was better than the former. The bread thus modified was quite palatable."

Treatment of Scabies with Petroleum.—DR. CONSTANTINE PAUL sends the following formula for "Petroleum soap" to *L'Abeille Médical*, April 30, 1889:

℞.—Soap	. . . . .	℥iij.
Petroleum	. . . . .	℥f.jss.
Alcohol	. . . . .	℥f.jss.
Wax	. . . . .	℥j.—M.

Two or three applications a day will result in complete recovery in one or two days.

The preparation is also said to be of value in ringworm.

Cancrum Oris Successfully Treated by Local Applications of Corrosive Sublimate.—DRS. PETER YATES and E. C. KINGSFORD report three cases of severe cancrum oris in children in the *Lancet* of May 4, 1889, which were cured by applications of corrosive sublimate. The affected parts were wiped off with a strong solution of perchloride of mercury (1 to 500), and afterward dressed with lint soaked in a similar solution (1 to 1000). The beneficial effects of this treatment were immediately observable; healthy granulations soon made their appearance, and the wound quickly contracted. As soon as a healthy condition of the wound was insured the treatment was discontinued, and simple dressings substituted.

Preventive Treatment of Diabetic Coma.—DR. STADELMANN, of St. Petersburg, is of the opinion that the coma in diabetes may always be prevented by prompt treatment. He regards the coma as an acid poisoning of the blood, and recommends strong doses of alkalies. He gives the following formulæ:

I. ℞.—Citric acid	. .	℥ij.
Carbonate of soda	. .	℥v.
Saccharine	. .	2 grains.
Carbonated water	. .	℥v.
Spirits of menthol	. .	gtt. iij.—M.

Two or three doses a day.

II. ℞.—Tartrate of soda	. .	℥ijss.
Carbonated water	. .	℥f.vss.
Saccharin	. .	2 grains.
Essence of lemon	. .	♏xl.—M.

The above Stadelmann claims to lessen greatly the œdema and prevent coma. The solutions may be diluted in pure water.—*Journal de Méd. de Paris*, April 28, 1889.

A Simple Inhaler.—It may be useful to others to mention the following very simple mode of inhaling volatile remedies, such as pumiline, menthol, eucalyptus, etc., for the relief of some affections of the throat and lungs. The device is suggested by E. E. MADDOX, M.D.

Coil a piece of paper into the shape of a cigarette, and fix it with gum. Then insert into one end a small uncompressed piece of absorbent cotton-wool, upon which a drop or two of the desired medicament has been poured. Air is now drawn through the tube by the patient, who holds the other end between his lips. This plan is by many patients, especially by men, preferred to the use of any form of respirator, or to inhalations mingled with steam. These last, moreover, have a relaxing effect in some atonic conditions of the throat.

Of a number of remedies, including menthol, inhaled in this way by a patient suffering from pulmonary phthisis, I found that oil of peppermint gave most satisfaction. A small tube of vulcanite like a cigarette-holder at one end, with a raised flange or border to be held within the lips, would doubtless answer still better; but an inhaler, which, when needed, can be made on the spot, has advantages of its own.—*The Practitioner*, May, 1889.

Creolin and Cholera Bacteria.—DRS. S. SIRENA and G. AGLESSI, of Florence, have found that even weak solutions of creolin act most powerfully upon the cholera bacilli. Eight to ten drops of a three per cent. solution of creolin added to a culture of pure cholera bacilli will sterilize the latter in five minutes; four drops will sterilize it in an hour, and five drops in half an hour. It has, however, been ascertained that solutions of creolin lose their strength in time, and should, therefore, be always made fresh. Creolin solutions also immediately sterilized cultures containing typhoid bacilli.—*Centralbl. für klin. Med.*, May 11, 1889.

For the Removal of Freckles.—

℞.—Chloride of ammonium. . . ℥f.j.
Hydrochloric acid. . . . ℥f.jss.
Glycerine . . . . . ℥f.j.
Lait virginal[1] . . . . ℥f.jss.—M.

Apply to the freckles morning and evening with a camel's-hair brush. Their complete disappearance is said to be speedy.—*L'Union Médicale*, April 25, 1889.

A New Mydriatic.—BAMBERGER and MÜLLER (*Berichte der Chem. Ges.*) have prepared from hydronaphthylamine a compound which promises to prove a powerful mydriatic, bearing the systematic name of tetra-hydro-beta-naphthylamine, and having the formula $C_{10}H_7H_4NH_2$. According to Professor Filehne, of Breslau, the instillation of a small quantity of a five per cent. solution causes the dilatation of the pupil of the eye treated only, though after absorption of a minute quantity both eyes become affected. The dilatation is greater than that produced by atropine. This compound is said (*Chemical Gazette*) to act as a mydriatic by stimulating the nerve-endings instead of by paralyzing the muscles of contraction as does atropine.—*The British Med. Journ.*, May 18, 1889.

Quinine used Hypodermatically in Malaria.—DR. J. A. CORREA DE CARVALHO has recently used hypodermatic injections of quinine in cases of malaria with marked success. He considers that the intolerance of quinine by the stomach is often the cause of its uselessness in malaria. He uses the following formula for injection:

℞.—Hydrochlorate of quinine . . 15½ grains.
Hydrochloric acid . . . q. s.
Distilled water . . . . 32m.—M.

The Care of the Hands of Surgeons.—The hands of surgeons are frequently roughened and cracked by frequent immersion in bichloride and carbolic acid solutions. DR. GEORGE MAYER, of Berlin, has found that if, after they have been thoroughly washed, a small quantity of lanolin is rubbed over the hands of the operator, it will keep them smooth, and also do away with that unpleasant numbness which follows long immersion in strong antiseptic solutions. As a most agreeable preparation for chapped hands he give the following:

℞.—Lanolin. . . . . ℥jss.
Vanillin . . . . . 2 grains.
Oil of roses . . . . gt. j.—M.

—*Centratbl. für Chir.*, April 20, 1889.

Naphthol in the Treatment of Purulent and Granular Conjunctivitis.—The *Revue gén. de Clin. et de Thérap.*, April 25, 1889, gives the following formulæ, which have been used with success by DR. DUPORT in the ophthalmological clinic of Hôtel-Dieu in Paris.

I. For purulent infantile ophthalmia:

1. ℞.—α Naphthol . . . . 1 part.
Alcohol . . . . 3 parts.
Distilled water . . . 3000 "

Apply two or three times daily.

2. ℞.—α Naphthol . . . . 1 part.
Distilled water . . . 5000 parts.

Cauterize with nitrate of silver two or three times daily, and apply the above lotion six or eight times during the day.

II. For granular conjunctivitis:

℞.—β Naphthol . . . . 1 part.
Vaseline . . . . . 300 parts.

To be applied daily. The strength of the ointment may be increased according to indications.

III. In pannus the following has been used with success:

℞.—α Naphthol . . . . 1 part.
Vaseline . . . . . 300 parts.

Apply every morning.

Also

℞.—α Naphthol . . . . 1 part.
Distilled water . . . . 2500 parts.

To be used as a lotion four times daily.

Treatment of Alopecia.—

℞.—Tincture of jaborandi, Tincture of cantharides, Soap liniment, Tincture of pyrethrum . . āā ℥ijss.
Spirits of citron, Tincture of tolu, Tincture of vanilla . . āā ℥jss.

Apply every morning and evening with friction.—*Revue de Thér. Med.-Chir.*, May 1, 1889.

Treatment of Corns.—DR. C. MCDERMOTT writes to the *British Medical Journal*, April 28, 1889, that a saturated solution of salicylic acid in flexible collodion is a most efficient remedy for corns. The solution should be applied to the corns twice a day. In less than two weeks their removal will be complete.

The Influence of Moderate Exercise upon the Digestion.—DR. COHN (*Centralblatt für klinische Medicin*, May 4, 1889) has recently conducted a long series of careful experiments relative to the influence of moderate exercise upon digestion. His experiments were confined to dogs, and his results are as follows: When the animal is at rest the digestion begins in an hour after the food has been taken, is at its height in two hours and then gradually decreases until it is complete, the entire process taking about five hours. An entirely different result, however, was observed in dogs taking moderate exercise after the meal. In these the process of digestion was not at its height until five hours after the food had been taken and was not complete in six hours. Dr. Cohn concludes that exercise retards digestion in dogs at least.

Artificial Carlsbad Salts.—DR. ZIEMSSEN, in the *Revue de Thér. Méd.-chir.*, May 15, 1889, gives the following formula for artificial Carlsbad salts:

℞.—Sulphate of sodium . . . 40 parts.
Carbonate of sodium . . 6 "
Chloride of sodium . . . 1 part.—M.

Dissolve in hot water, evaporate, and pulverize the residue. Dose, half teaspoonful in hot water.

[1] *Lait virginal*, French cosmetic, prepared by dropping alcoholic tincture of benzine into water until the mixture becomes perfectly white.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE . . . . . $5.00.

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JUNE 8, 1889.

THE CALAMITY AT JOHNSTOWN, AND ITS LESSONS.

THE appalling disaster which has desolated the valley of the Conemaugh with its overwhelming destruction of life and property, has aroused a mighty throb of sympathy and a generous and widespread response to the cry for relief. The medical profession, true to its traditions and instincts, has promptly considered the needs of general medical assistance, and at Pittsburg and Philadelphia relief corps were immediately organized, the volunteers dropping their work at home to repair to the scene of the floods to give their professional services to its maimed and suffering victims.

The members of our own profession have been no less unfortunate than the other inhabitants of the valley—some have lost their lives; others have survived to find swept away some or all of their families, their homes, and their property. To take measures for their relief, the President of the College of Physicians of Philadelphia and the President of the Philadelphia County Medical Society promptly called meetings and Dr. W. W. Keen, President of the County Society, at once authorized Dr. Flick, a member of the Society now at Johnstown, to draw upon him for a liberal sum to aid in supplying the more immediate and pressing needs of the physicians of the valley and their families.

THE MEDICAL NEWS has ever endeavored to realize that its readers regard it primarily as a medical *newspaper*. During the past seven or eight years no great public event exhibiting any phase of interest to the medical profession has been allowed to pass without the fullest and promptest details being procured and laid before its readers. In pursuance of this policy, a member of the editorial staff was promptly despatched to Johnstown, and in spite of the great difficulties to be overcome, both in getting to the spot and in transmitting the news over the overburdened wires, a concise and scientifically interesting report of his investigations will be found in another column.

HE has read history to little purpose who does not perceive that in every catastrophe there is concealed the germ of some future benefit to mankind. The injuries inflicted, and the sorrows and sufferings endured, have an important lesson for the immediate survivors, for the community, and for every individual in what art or business soever he may be engaged. The events that occurred recently in Western Pennsylvania possess psychological, hygienical, and medical interests of supreme value. We purpose, now and here, to set before our readers such views of them as may seem conformable to the state of facts brought out by these terrible experiences.

The influence exerted upon the health of the living by the decomposition of dead bodies is now the supreme question. A single phrase states the truth of the matter. It has been said that "It is the living, not the dead, man we have to fear." Although a truth, it requires a modification under some circumstances. As the most pressing question of municipal hygiene at Johnstown, how should it be decided?

Many facts have proved that the gases and organic matters developed by decomposition of human remains are not necessarily injurious. It may be said, indeed, they are not injurious at all, if due care be given to personal hygiene, and quick escape of gases be secured by proper ventilation.

The gases of decomposition and the organic matter may under some circumstances act injuriously. Breathing continuously air thus contaminated, and never pure air at any time, human health gradually deteriorates. Special diseases are not produced, but the composition of the blood and the relative proportion of red and white corpuscles are changed, ulceration of the mucous membrane of the lower small intestine takes place, and the nutrition fails.

The cachectic state thus induced favors the development of such diseases as typhoid, diphtheria, etc.

Under some circumstances human remains can be the source of disease. Subjects dead of smallpox, diphtheria, fevers, etc., contain the germs of these diseases—the *materies morbi*—for a short time; but when decomposition takes place the contagium is destroyed. Decomposition of the body, which effects the return to its primal elements, is nature's mode of ending the enormous evils which would have filled the space between death and life.

Decomposition is a function of living organisms; it is a fermentation in which microörganisms play the essential part. The organisms in their growth and pullulation consume materials and resolve themselves into new products. It was most unfortunate that sentimental considerations, founded in a totally false conception of things, should have interfered with the burning of bodies started by accident. The physicians advised—if we understand aright—that the large collection of bodies in a great accumulation of drift which was then briskly burning, be permitted to remain and be disposed of by burning—a swift return to the primary elements, instead of the return by slow combustion when placed in the ground.

Although the earth above a decaying body acts as an oxidizer, it is clear that in the burials now going on at Johnstown sufficient regard cannot be paid to sanitary considerations. Insufficient care in burying the bodies, shallow graves, and a loose soil combine to make the result exceeding hurtful, for the air will contain at all times the gases of decomposition. Although special diseases are not produced, the health of individuals breathing such an atmosphere must deteriorate and make them suitable subjects for the rise and spread of serious epidemics. Furthermore, in so many subjects there could hardly fail to be cases of disease, such as typhoid, diphtheria, scarlet fever, whose germs have strong viability, and will survive all the agents employed for their destruction, because protected by their environment.

Morbific matters—disease germs—during the process of decomposition now going on, will be liberated, and under the circumstances secure admission to potable waters. We understand that these newly improvised graves are placed on the hillsides and in situations for their products of decomposition to secure admission to the surface wells, to the springs and streams about them. How certain it is that in course of time disease germs will thus enter the system of many people, with the usual result.

If the bodies must be buried, what disinfectants beside heat or destruction by fire can be utilized here?

The gases of decomposition may be destroyed by such agents as chlorine and the chlorides, under these circumstances, if effectively used and in sufficient quantity; but even if this be done it is unlikely that the pathogenic microbes will be disposed of, for in inner parts, surrounded by a tough environment, they cannot be reached by disinfectants of the most powerful kind. Chloride of lime is the best agent to be used for this purpose, because it contains much free chlorine, if *it be genuine—i. e.*, if it contains the proper proportion of chlorine gas.

It does not suffice, however, to place chloride of lime in the grave and on the body. If the disinfection is to be effective, the abdominal cavity at least should be opened and the lime placed there in full quantity.

THE PROPHYLAXIS OF TUBERCULOSIS.

SEVEN years have elapsed since the announcement of Koch's discovery of the tubercle bacillus, and his demonstration of its causal relation to the entire group of the tuberculous diseases. On the whole, it cannot be said that the hopes to which that discovery gave rise have been realized. The treatment of pulmonary phthisis has during this time undergone in rapid succession a series of startling and erratic changes. In so far as these changes have had for their basis any theory concerning the direct destructive action of drugs upon the bacillus within the tissues of the organism, they have led, one after another, to disappointment. To those who have been at the pains of informing themselves of the nature of the parasite, its mode of growth and distribution in the tissues, and the way in which its local and constitutional effects are produced, the rigid experiments of Trudeau were not needed to demonstrate the uselessness of attempts to discover a direct germicide treatment.

The attention of the profession has, however, been aroused, and the treatment of tuberculosis, and in particular of consumption, has once more become a question of the day. This time, thanks to the science of bacteriology, it is no question of mere speculation, but has for its point of departure a con-

nected group of well-ascertained facts. Dietetics, hygiene, respiratory gymnastics, climate have been brought into closer and more profitable service to the consumptive. If medicaments selected upon false theories have proved useless, the extra-medicinal management of the disease has been more reasonable and effective. Life has often been prolonged and cures have been occasionally accomplished. But the disappointments of a too sanguine therapy have been more than counterbalanced by the results of the efforts to which they have stimulated the profession. Among these results have been, not only the dispersion of many traditional errors, but also the acquisition of exact knowledge of the life-history of the tubercle bacillus, both within the animal organisms which it infests, and outside of them.

CORNET has shown (*Zeitschrift für Hygiene*, V. Band) that the dust collected from one hundred and forty-seven different hospitals, insane asylums, private houses occupied by consumptives, and crowded streets, contained in forty instances tubercle bacilli; in sixty-nine it was, however, free from them; and in the remainder the death of the animals used in the experiments being quickly brought about by the action of other bacteria, the result was indeterminate. The dust from twenty-seven rooms not occupied by consumptives showed no tubercle bacilli. Even in the apartments of severe cases, bacilli were not discovered save when the patient expectorated into handkerchiefs or upon the floor, and in no case was the dust of the walls infectious where spit-cups were exclusively used, though the bacilli were abundant in the sputum.

The deduction that the tubercle bacillus is only found in the immediate neighborhood of consumptives, is from these facts obvious. Cornet's further investigations (*Berliner klin. Wochenschrift*, 1889, Nos. 12, 13, 14, 15) strongly support the conclusion that infection occurs chiefly from dried sputum floating in the atmosphere and drawn into the lungs by the inspired air.

When infection takes place by direct inoculation elsewhere than in the lungs, the early lesions are invariably found at the point of inoculation and in the neighboring lymph-glands. The assumption that the lungs are the seat of an especial predilection for the development of the bacillus is absolutely false. The preponderance of pulmonary consumption over other forms of tuberculosis is to be explained by the greater exposure of the organs of respiration to inoculation.

Cornet regards the danger of infection by means of bacilli thrown off with the fecal matter in ulceration of the intestine, or in the urine in urino-genital tuberculosis, as extremely slight. Intestinal tuberculosis, from the use of imperfectly cooked meat from tuberculous animals, he regards as rare. Of greater importance is the consumption of milk from tuberculous cows, unless it has been thoroughly cooked, this being doubtless a frequent cause of intestinal tuberculosis in children.

The author refers to the experiments of Naegeli and others, which show that air passing over a moist surface does not take up bacilli or spores. He concludes from these experiments that it is absolutely impossible for the air-passages, for tuberculous cavities, or for the expectoration, so long as it remains moist, to render the expired air infectious. The consumptive is only dangerous by means of his expectoration, and not even by this so long as it remains moist. The moment that it dries it passes beyond our control, and, in the form of fine bacilli-bearing particles wafted about in the air, becomes the ordinary means of transmission.

Cornet concludes his interesting paper with a series of definite rules for the treatment of the expectorated matters, and for the prevention of the distribution of the tubercle bacilli. The subject as thus presented reduces the prophylaxis of tuberculosis to the simplest conceivable form, but, owing to the practical difficulties in the way of carrying it into effect, it would be Utopian to look forward to immediate results of importance on a great scale.

Cornet's suggestions have, however, been formulated in a series of regulations presented to the public by the President of the Police Board in Berlin, which are to be found in the issue of THE MEDICAL NEWS of May 25th, and in other columns of our issue of to-day we present an admirable address before the Pennsylvania State Medical Society by Dr. J. C. Wilson, reviewing the latest advances in the etiology and prophylaxis of tuberculosis, and a report for popular use embodying the knowledge of the day on its prevention, which has been prepared by Drs. Biggs, Prudden, and Loomis, at the request of the Board of Health of New York City.

THE fortieth annual meeting of the American Medical Association will be held at Newport, R. I.,

from June 25th to 28th, under the Presidency of Dr. W. W. Dawson, of Cincinnati. The general addresses will be delivered as follows: In Medicine, by Dr. William Pepper, of Philadelphia; in Surgery, by Dr. P. S. Conner, of Cincinnati; in State Medicine, by Dr. W. H. Welch, of Baltimore. The list of papers to be read in the various sections is lengthy and includes an unusually large number of attractive titles, and reflects great credit upon the officers of sections to whose energy this excellent programme is largely due.

The *Chairmen* of Sections are as follows:

Medicine, Dr. F. C. Shattuck, of Boston.

Surgery, Dr. N. P. Dandridge, of Cincinnati.

Obstetrics, Dr. W. H. Wathen, of Louisville.

State Medicine, Dr. J. Berrien Lindsley, of Nashville.

Ophthalmology, Dr. George E. Frothingham, of Ann Arbor.

Laryngology and Otology, Dr. W. H. Daly, of Pittsburg.

Diseases of Children, Dr. J. A. Larrabee, of Louisville.

Medical Jurisprudence, Dr. J. G. Kiernan, of Chicago.

Dermatology and Syphilography, Dr. L. Duncan Bulkley, of New York.

Dental and Oral Surgery, Dr. F. H. Rehwinkel, of Chillicothe.

Dr. Horatio R. Storer, Newport, is Chairman of the Committee of Arrangements.

We understand that one of the principal social features of the meeting will be a steamboat excursion after adjournment on Friday, given by the Rhode Island Medical Society, to Providence for the inspection of the Rhode Island and Butler Hospitals and, on the return trip, a stop will be made at a shore resort, when the members will be introduced to the pleasures of an old-fashioned clam-bake.

The programme, with its long list of admirable papers, gives every promise of this being one of the most interesting and attractive meetings that the Association has ever held.

DR. A. L. GIHON, Chairman, requests us to state that the Rush Monument Committee will meet in Right Gallery Room at Music Hall, Newport, R. I., on Tuesday, June 25th, at 1 P. M., or immediately after adjournment of the morning session of the American Medical Association. The attendance of all interested in this commendable and patriotic project is invited.

Collections and subscriptions should be forwarded to the treasurer, Dr. Joseph M. Toner, 615 Louisiana Avenue, Washington, D. C., before June 15th.

OWING to the interruption to railroad travel caused by the floods and the impossibility of a large proportion of the members reaching Pittsburg last Tuesday for the annual meeting of the Pennsylvania State Medical Society, those present very properly adjourned the meeting until September, without further transaction of business.

THE Maine Medical Association will hold its thirty-seventh annual meeting at Portland, on Tuesday, Wednesday, and Thursday of next week, under the presidency of Dr. S. H. Weeks, of Portland.

THE New Hampshire Medical Society will hold its ninety-eighth anniversary on June 17th and 18th, at Concord, under the presidency of Dr. Samuel C. Whittier, of Portsmouth.

DR. SAMUEL PRESTON MOORE, formerly Surgeon-General in the Confederate Army, died at Richmond, Va., on the 31st of May, aged seventy-four. He was appointed an assistant surgeon in the U. S. Army in 1856, and served in that capacity through the Mexican War and up to the time of the passage of the act of secession by his native State, South Carolina, when he resigned to enter the service of the Confederacy. After the close of the war he settled in Richmond. He took an active interest in educational matters and was a member of the Richmond School Board.

SPECIAL ARTICLE.

THE MEDICAL ASPECT OF THE DISASTER AT JOHNSTOWN.

(*By Telegraph from a Staff Correspondent.*)

JOHNSTOWN, PA., June 6, 1889.—Notwithstanding the fact that many of the reporters of the daily papers have sent messages from here indicating that diseases the result of exposure are exceedingly common, the fact is, that in the three largest hospitals very few cases of any kind exist, and, in over ninety per cent. of these, the individuals are suffering from injuries occurring both during and after the flood. The cases of pneumonia are very few, and the report that measles is to a large extent epidemic is entirely false. The truth is, that one or two children have

exhibited symptoms of this disease, the reports of which, in the present state of popular excitement, have grown in their severity with each mile that they have travelled. So far as the spread of any disease, such as this, is concerned, we feel quite confident that the conditions present are, with a few exceptions, eminently prophylactic in their character. The children who suffer are living in tents, which are necessarily very thoroughly ventilated, and crowding is impossible. So far as we have been able to learn, the history of any exposure on the part of the children affected with measles is very dim.

Too much care cannot be exercised in the selection and dispensing of much of the second-hand clothing which is sent forward in the relief trains by charitable persons. From some of the clothing which we saw distributed, we feel sure that lack of such care may readily result in the production of a large amount of contagious disease.

The danger of malarial poisoning is, we believe, not present, simply because the conditions favorable to the production of such miasms are absent. The water, sweeping through the valley with enormous force, has carried, in the majority of cases, the soft mud of the river banks to distant and low-lying bottom-lands, and has covered the entire site of Johnstown with a layer of pure sand and gravel varying in depth from a few inches to a foot. As the consequence of this, all cesspools have not only been thoroughly washed out, but afterward filled with sand; every particle of dirt and city filth has been washed away, and it would be hard to find, hygienically speaking, a more cleanly spot than the main portions of what was once Johnstown. The danger will be the accumulation of new filth, owing to the large number of strangers living in tents and the outdoor life of the survivors.

There is absolutely no use in sending more physicians here, save that by their training they may assist in the carrying out of measures belonging to the realm of preventive medicine. With the exception of a few who are assisting in hospitals, the majority of Philadelphia physicians have been detailed for the purpose of overseeing the thorough cremation of all dead animals. The only other measures which are adopted are those directed against the decomposition of human flesh, which popular clamor will not allow to be touched by fire. All other attempts to disinfect such sources of disease, without the aid of great heat, cannot prove but useless, for the bodies, as a general rule, are piled up in a mass of rubbish made up of old lumber, which is arranged in such a way that it is doubtful if a river of disinfectants could reach them, the débris acting as a shed. In an endeavor to obtain the identification of bodies, they have been kept, prior to this date, for too long a time previous to burial. This has been largely done away with by improved rules, ordered by cooler heads from outside relief corps.

The mental condition of almost every former resident of Johnstown is one of the gravest character, and the reaction which will set in when the reality of the whole affair is fully comprehended can scarcely fail to produce many cases of permanent or temporary insanity. Most of the faces that one meets, both male and female, are those of the most profound melancholia, associated with an almost absolute disregard of the future. The nervous system shows the strain it has borne by a tremulousness of the hand and of the lip, in man as well as in woman. This nervous state is further evidenced by a peculiar intonation of words, the persons speaking mechanically, while the voices of many rough-looking men are changed into such tremulous notes of so high a pitch, as to make one imagine that a child, on the verge of tears, is speaking. Crying is so rare that your correspondent saw not a tear on any face in Johnstown, but the women that are left are haggard, with pinched features and heavy, dark lines under their eyes. Indeed, the evidence of systemic disturbance is so marked in almost every individual who was present at the time of the catastrophe, that it is possible with the eye alone to separate the residents from those outside.

Every thing required in the way of surgical appliances seems to be on hand, but medicines are scarce and will probably be needed much more in the next few days than heretofore.

A fact in favor of the controlling of any malady is to be found in the very general exodus of the townspeople who crowd the platform of departing trains. There can be no doubt that this movement should be encouraged to the greatest possible extent, and it would be well if places away from Johnstown, at not too great distance, could be opened for the reception of those who, while not entirely disabled, are useless at home.

The scarcity of pure spring water which is not tainted by dead animal matter is a pressing evil for consideration, but we doubt if this is as important a fact at Johnstown as it is further down the river, owing to the large amount of decomposing flesh in the water at this latter point. No disinfectant can reach such a cause of disease, save the action of the large volume of water which dilutes all poisonous materials.

The State Board of Health should warn the people of the portions of the country supplied by the Conemaugh of the danger of drinking its waters for weeks to come.

ON THE PREVENTION OF TUBERCULOSIS.

THE following report has been forwarded to the Board of Health of New York City in response to the accompanying resolution of the Board.

Resolved, That Drs. T. M. Prudden, H. M. Biggs, and H. P. Loomis, the pathologists of this department, be and are hereby requested to formulate a brief and comprehensive statement regarding the contagiousness of tuberculosis in man, stating therein the evidence of the same and recommending in the briefest possible manner practicable the simplest means of protection from its influence.

REPORT.

The disease known as tuberculosis and, when affecting the lungs, as pulmonary tuberculosis (consumption), is very common in the human being and in certain of the domestic animals, especially cattle. About one-fourth of all deaths occurring in the human being during adult life is caused by it, and nearly one-half of the entire population at some time in life acquires it. The disease is the same in nature in animals and in man, and has the same cause.

It has been proven beyond a doubt that a living germ, called the tubercle bacillus, is the cause and the only cause of tuberculosis. It does not seem necessary to state the facts upon which this assertion is based, for the observation first made by Robert Koch, in 1882, has been confirmed so often and so completely, that it now constitutes one of the most absolutely demonstrated facts in medicine.

Tuberculosis may affect any organ of the body, but most frequently first involves the lungs. When the living germs find their way into the body they multiply there, if favorable conditions for their growth exist, and produce small new growths or nodules (tubercles) which tend to soften. The discharges from these softened tubercles, containing the living germs, are thrown off from the body. In pulmonary tuberculosis these discharges constitute, in part, the expectoration. The germs thus thrown off do not grow outside the living human or animal body, except under artificial conditions, although they may retain their vitality and virulence for long periods of time, even when thoroughly dried. As tuberculosis can only result from the action of these germs, it follows from what has just been said, that when the disease is acquired, it must result from receiving into the body the living germs that have come from some other human being or animal affected with the disease.

It has been abundantly established that the disease may be transmitted by meat or milk from tubercular animals. The milk glands in milch cows often become affected with the disease when their lungs are involved, and the milk from such animals may contain the living germs and is capable of producing the disease. Among stall-fed dairy cows 20 or 30 per cent. are sometimes found to be affected with the disease. Tubercular animals are also frequently killed for food; their flesh sometimes contains the germs, and if not thoroughly cooked is capable of transmitting the disease. Boiling the milk or thoroughly cooking the meat destroys the germs. Although the meat and milk from tubercular animals constitute actual and important sources of danger, the disease is acquired, as a rule, through its communication from man to man.

Tuberculosis is commonly produced in the lungs (which are the organs most frequently affected) by breathing air in which the living germs are suspended as dust. The material which is coughed up, sometimes in large quantities, by persons suffering from consumption contains these germs, often in enormous numbers. This material when expectorated frequently lodges in places where it afterward dries, as on the streets, floors, carpets, clothing, handkerchiefs, etc. After drying, in one way or another, it is very apt to become pulverized and float in the air as dust.

It has been shown experimentally, that dust collected from the most varied points, in hospital wards, asylums, prisons, private houses, etc., where consumptive patients are present, or have been present, is capable of producing tuberculosis in animals when used for their inoculation. Such dust may retain for weeks its power of producing the disease. On the other hand, dust collected from rooms in institutions or houses that have not been occupied by tubercular patients does not produce the disease when used for the inoculation of animals.

These observations show that where there are cases of pulmonary tuberculosis, under ordinary conditions, the dust surrounding them often contains the tubercle bacilli; and persons inhaling the air in which this dust is suspended may be taking in the living germs. It should, however, be distinctly understood that the breath of tuberculous patients, and the moist sputum, received in proper cups, are not elements of danger, but only the dried and pulverized sputum. The breath and moist sputum are free from danger, because the germs are not dislodged from moist surfaces by currents of air. If all discharges were destroyed at the time of exit from the body, the greatest danger of communication from man to man would be removed.

It then follows, from what has been said, that tuberculosis is a distinctly preventable disease.

It is a well-known fact that some persons, and especially the members of certain families, are particularly liable to tuberculosis, and this liability can be transmitted from parents to children. So marked and so frequent is this liability, and so frequent is the development of the disease in particular families, that the affection has long been considered hereditary. We now know that tuberculosis can only be caused by the entrance of the germ into the body; and that this transmitted liability simply renders the individual a more easy prey to the living germs when once they have gained entrance.

The frequent occurrence of several cases of pulmonary tuberculosis in a family is, then, to be explained, not on the supposition that the disease itself has been inherited, but that it has been produced after birth by transmission directly from some affected individual. Where the parents are affected with tuberculosis the children from the earliest moments of life are exposed to the disease under the most favorable conditions for its transmission, for not only is the dust of the house likely to contain the bacilli, but the relationship also between parents and children, especially between mother and child, are of that close and intimate nature especially favorable for the transmission by direct contact.

If, then, tuberculosis is not inherited, the question of prevention resolves itself, principally, into the avoidance

of tubercular meat and milk, and the destruction of the discharges, especially the sputum, of tubercular individuals. As to the first means of communication, those measures of prevention alone answer the requirements which embrace the governmental inspection of dairy cows and of animals slaughtered for food, and the rigid exclusion and destruction of all those found to be tubercular.

For the removal of the second means of communication—*i. e.*, the sputum of tubercular individuals—the problem is simple when the patients are confined to their rooms or houses; then wooden or pasteboard cups with covers should always be at hand for the reception of the sputum. These cups are supported in simple racks, and at least once daily, or more frequently if necessary, should be removed from the racks and thrown with their contents into the fire.[1]

The disposition of the expectoration of persons who are not confined to their rooms or homes is a far more difficult problem. The expectoration certainly should not be discharged on the street, and the only practical means for its collection seems to be in handkerchiefs, which, when soiled, should at the earliest possible moment be soaked in a solution of five per cent. of carbolic acid and then boiled and washed. Handkerchiefs thus soiled are exceedingly dangerous factors in distributing tubercle bacilli; for when the sputum becomes dry, it is easily separated in flakes from the cloth and then soon becomes pulverized and suspended as dust.

It becomes evident from what has been said, that the means which will most certainly prevent the spread of this disease from one individual to another, are those of scrupulous cleanliness regarding the sputum. These means lie largely within the power of the affected individual. It is, furthermore, to be remembered that consumption is not always, as was formerly supposed, a fatal disease, but that it is in very many cases a distinctly curable affection.

An individual who is well on the road to recovery may, if he does not with the greatest care destroy his sputum, diminish greatly his chances of recovery by self-inoculation.

While the greatest danger of the spread of the disease from the sick to the well is in private houses and in hospitals, yet, if this danger is thoroughly appreciated it is, for the most part, quite under control, through the immediate destruction of the sputum and the enforcement of habits of cleanliness. But in places of public assembly, such as churches and theatres, particularly the latter, the conditions are different, and safety would seem to depend largely upon a dilution and partial removal of the floating and possibly dangerous dust by means of adequate ventilation.

Rooms in private houses and hospital wards that are occupied by phthisical patients should from time to time be thoroughly cleaned and disinfected, and this should always be done after they are vacated, before they are again occupied by other individuals.

Steamship companies should be obliged to furnish separate apartments for consumptive persons, so that no person in the exigencies of travel need be forced to share his room with one who might be a source of active danger to him.

We desire especially to emphasize the following facts:

1st. That tuberculosis is a distinctly preventable disease;

2d. That it is not directly inherited; and

3d. That it is acquired by the direct transmission of the tubercle bacillus from the sick to the healthy, usually by means of the dried and pulverized sputum floating as dust in the air.

The measures, then, which are suggested for the prevention of the spread of tuberculosis are:

1st. The security of the public against tubercular meat and milk, attained by a system of rigid official inspection of cattle;

2d. The dissemination among the people of the knowledge that every tubercular person may be a source of actual danger to his associates, if the discharges from the lungs are not immediately destroyed or rendered harmless; and

3d. The careful disinfection of rooms and hospital wards that are occupied or have been occupied by phthisical patients.

HERMANN M. BIGGS,
T. MITCHELL PRUDDEN,
HENRY P. LOOMIS,
Pathologists to the New York City Health Department.

[1] A cheap and efficient cup answering this purpose is now on the market and is supplied by druggists.

IN accordance with the principles of the prophylaxis of phthisis advanced by Dr. Cornet, DR. DETTWEILER, of Frankenstein, has designed the following pocket spit-cup or flask, which will obviate the necessity of expectorating either on the floor, or street, or into a handkerchief.

The flask, which is described in the *Therap. Monatshefte*, May, 1889, holds about three fluid-ounces. It is made of blue glass, and is flat. There are two openings, one at the top and one at the bottom; both have metallic screw-caps. The upper opening, which is the largest, has, in addition, a spring cover or cap, which closes tightly; also, a polished metal funnel, which reaches half-way down into the flask. This funnel acts similarly to that of certain ink bottles, and prevents the spilling of the contents of the flask, even if the cap is left open. The lower opening is designed to aid a thorough cleaning of the flask when necessary. The instrument can be sold at a cost of less than fifty cents, can be kept perfectly clean, closes securely, and is altogether admirably adapted to the requirements of consumptives.

SOCIETY PROCEEDINGS.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Eleventh Annual Congress, held in Washington, D. C., May 30 and 31, and June 1, 1889.

THURSDAY, MAY 30TH.—MORNING SESSION.

THE PRESIDENT, DR. ETHELBERT CARROLL MORGAN, of Washington, called the Association to order, and delivered the

PRESIDENTIAL ADDRESS.

He welcomed the Association to the National Capital, and said that its noble work during its eleven years of existence has resulted in placing laryngology upon a substantial basis, and in demonstrating its truths and benefits alike to the profession and to suffering humanity. The outlook for laryngology was never brighter than at present. The tenth volume of the *Transactions* is now in press, and in addition to the papers read at the last meeting of the Association, contains a table of contents of all the papers read to the Association since its organization.

DR. E. CARROLL MORGAN then presented a

REPORT OF THE REMOVAL OF A SUPERNUMERARY TONSIL.

The patient, a male, æt. twenty-six years, vigorous, and otherwise healthy, came under observation September 7, 1886, with what he feared was malignant disease of the pharynx. The growth was first discovered four years previous. It had occasioned considerable pain, especially after smoking. During the past two months the growth had rapidly increased in size, and the pain had become of a shooting character, extending to the ears, larynx, and top of the head. Examination revealed a pendant tumor between the right palatine folds near the uvula, and protruding beyond their borders half an inch. The tumor was as large as a small almond. Its color, as well as that of the pillars, was a dusky red. Slight engorgement of the cervical glands appeared to exist. The patient's mother had died of cancer of the breast. Local and general treatment having no effect, the tumor was excised, and the raw surface cauterized with the galvano-cautery. In ten days the wound had healed. The patient was recently examined, and there has been no recurrence, now four years after the operation. The specimen removed was examined by Dr. W. M. Gray, Microscopist to the Army Medical Museum, who stated that its structure was identical with that of a faucial tonsil which had undergone hypertrophy. The location and microscopic characters of this tumor, as well as the history of the patient prior to and subsequent to the operation, prove that this was a hypertrophied accessory or supernumerary tonsil, an exceedingly rare anomaly. A search of the literature had revealed only two other cases of a similar character reported by Jurasz, in 1885. In the first case the tumor was as large as a hen's egg, and was found to spring from the lower anterior portion of the right posterior pillar by a small and short pedicle. It was removed, and found, on microscopic examination, to present the structure of a hypertrophied tonsil. In the second case the tumor was of the size of a hazel-nut, and attached below the right tubal prominence. The microscope revealed a structure similar to that of the faucial tonsil.

Conclusions.—1. The lymphoid follicles of the soft palate and pharynx are liable to be aggregated, resembling in arrangement the faucial tonsil. 2. The condition is exceedingly rare, since, excepting the so-called "pharyngeal tonsil," the author has found but one case reported. 3. These lymphoid follicles are also liable to hypertrophy. 4. Such hypertrophies probably occur oftener than is generally supposed. 5. The indications for operative interference in this condition are identical with those for the faucial tonsil.

DR. D. BRYSON DELAVAN, of New York, thought that possibly cases of supernumerary tonsil were not so infrequent as was commonly supposed. Pedunculated tumors of the tonsil which on examination show a fibroid structure are not rare, and it may be that they are degenerated supernumerary tonsils, just as the tonsil may, from long-continued inflammation, become the seat of fibroid change.

DR. GEORGE W. MAJOR, of Montreal, then read a paper on

THE RELATION BETWEEN FACIAL ERYSIPELAS AND ERYTHEMA, ON THE ONE HAND, AND INTRA-NASAL PRESSURE ON THE OTHER.

The following cases were cited as showing that facial erysipelas may be produced by nasal conditions, particularly when they are productive of pressure.

Case I.—A girl, aged twelve years, came under observation in March, 1884, for the treatment of nasal catarrh. There was a general hypertrophic condition, with pressure of the middle turbinated body of one side against the septum. On the cheek bone of the same side there was a red patch of erythema which had existed for five months. Treatment of the nasal condition by scarification, puncture, and galvano-cautery was followed by disappearance of the erythematous rash, and it has not returned.

Case II.—A child, four years of age, was seen in February, 1885, suffering with facial erysipelas, commencing on the bridge of the nose and extending to the cheeks. It had already lasted five days, and was not disposed to yield to treatment. Both nostrils were occluded by swelling. All treatment directed to the relief of the erysipelas was suspended, and attention directed to the relief of the nasal condition. In twenty-four hours the erysipelas had disappeared.

Case III.—In the winter of 1884, a boy, aged twelve years, the subject of recurring attacks of erysipelas, was seen with an attack involving the nose and cheeks. Nasal injections were alone used, and the erysipelas disappeared in thirty-six hours.

Case IV.—February, 1889, a female, aged fifty-six, presented herself with an erythematous patch on the left cheek. This had lasted four months. There was swelling of the left turbinated bone, which pressed against the septum. Under treatment of the nose the erythema disappeared in the course of a week.

Six other cases were alluded to, in which the same condition was seen.

DR. J. O. ROE, of Rochester, had seen a number of cases of erythematous rash due to the nasal trouble. A case recently seen was that of a girl, twenty-three years of

age. There was a very red erythematous patch on the face associated with blebs. She had been treated by various physicians without benefit. In both nares the middle turbinated bodies pressed firmly against the septum. This was relieved and there was immediately a subsidence of the erythematous trouble. He, however, could not admit that erysipelas is due *per se* to the intra-nasal trouble. He held that erysipelas is an infectious disease due to a distinct germ. The presence of erosions in the nasal cavity would render the patient more liable to become infected.

DR. J. N. MACKENZIE, of Baltimore, said that the relation between erythema of the nose and face and intra-nasal trouble had been recognized centuries ago in the times of Willis and by Sylvius. He himself had seen many cases of this kind, but he had never seen true erysipelas due to this cause. So-called facial erysipelas seems to be comparable to an accentuation of the act of blushing—a sort of chronic blush.

DR. WILLIAM H. DALY, of Pittsburg, was not a believer in the theory of intra-nasal pressure. The evils referred to pressure are really due to intra-nasal turgescence. The condition of erythema is nothing more than a condition of hyper-nutrition due to a permanently dilated and enlarged blood supply. He believed that the term chronic facial erysipelas is a misnomer.

DR. F. I. KNIGHT, of Boston, remarked that in these cases of erythema of the nose and face he always looked for nævus and very often found it. Where the trouble has been relieved, the affection of the skin has disappeared.

DR. D. BRYSON DELAVAN, had seen several of these cases, and in three or four the erysipelatous attacks have been severe. One case, a girl of seventeen years, had recurrent attacks of severe erysipelatous swelling from the alæ of the nose extending over the cheek. These recurred at intervals of two or three weeks. There was marked turgescence of the nasal mucous membrane. This was treated topically, and with the subsidence of the catarrhal trouble the attacks of erysipelas disappeared.

DR. SAMUEL W. LANGMAID, of Boston, then reported

A CASE OF ACUTE MULTIPLE ADENITIS (SEPTIC?) ŒDEMA OF THE LARYNX WITH SPONTANEOUS CURE.

He was called to see a lady, aged forty, who had been sick for seven days, under the care of an irregular practitioner. The patient was found restless, with an anxious expression, breathing with difficulty, and with a dry, croupy cough. There was no lividity of the face, but it was stated that during the preceding twenty-four hours there had been danger of strangulation. The submaxillary glands, as well as those in the region of the neck, were much swollen. Temperature 99°; voice fairly loud and clear; no enlargement of the tonsils; nothing unusual in the naso-pharynx. With the laryngoscope a tumor, apparently as large as a filbert, was seen occupying the posterior arytenoid space. The anterior third of the vocal cord could be seen approximated and scarcely moving during respiration. He learned that the throat had not been examined until four days after the commencement of the attack. As the patient was breathing fairly well it was decided to do nothing. If necessary, the tumor in the larynx was to be incised. A few hours later something was felt to break in the throat, and a free mucoid discharge took place. Three hours later, nothing could be seen but the erect epiglottis, with mucopurulent matter welling up. There was a continued discharge, but the relief to breathing was not complete. There had been, also, the discharge of half an ounce of pus. The discharge continued for several days, and the patient gradually recovered.

It was thought that the case was in all probability due to diphtheria, the evidences of which had passed away when the author examined the throat. The patient stated that at the commencement of the illness, the throat had been sore, and that on one side she had noticed red spots on which there had been a white covering.

DR. WM. C. GLASGOW, of St. Louis, read a paper on

AN ŒDEMATOUS FORM OF DISEASE OF THE UPPER AIR-PASSAGES.

He described an œdematous form of disease which had been epidemic around St. Louis for some two years. During the existence of this affection there has been a disturbance of the ordinary catarrhal throat troubles. In all cases of this disease there is found a pale, œdematous condition of the fauces. This is a solid œdema. A peculiar glistening appearance is at times very marked. In the majority of cases the soft palate is the seat of œdema. At times the nasal mucous membrane is found in the same condition. The epiglottis and different portions of the larynx may be involved. In some cases the true cords are markedly œdematous. A swollen condition of the veins, particularly the palatine veins, is present. This sometimes causes purpura-looking spots, and the mucous membrane appears mottled. In two cases these purpura-looking spots had been seen in the trachea. In one case enlarged veins were seen on the true cord. In some cases ulceration occurs. In some cases, in addition to œdema, there were patches of exudation in different parts of the throat. These when removed leave a bleeding surface. The symptoms of the disease and the appearance of the throat preclude the diagnosis of diphtheria. In six cases spots of mycosis were seen. Glandular enlargement of the neck is quite frequent. In two cases suppuration occurred.

The symptoms are constitutional and local. The affection occurs suddenly in persons of previous good health. There is langour, weakness, and general pains throughout the body. Headache is present, usually frontal, sometimes occipital. In many cases it is simply a dull heavy feeling, in others it is an intense violent throbbing pain. Pain in the back in the region of the sacrum is a characteristic symptom. Fever is present in varying degree. In the exudative cases, the disease commences with chill followed by fever, and the temperature may reach 105°. This soon passes off, and we have a subfebrile condition remaining, probably with a temperature of 101°. This continues a short time, and then there is a return to the normal temperature. When there is simply œdema, the temperature scarcely ever rises above 101° to 102°. This remains for only twelve hours, and during the remainder of the attack the temperature is normal. The pulse is always rapid, soft, and compressible; there has been no exception to this noted. The pulse ranges between 90 and 110 per minute. Profuse sweating is often present, especially during the night. It may be localized.

The local symptoms vary with the part of the throat

involved. Sometimes they are prominent, sometimes they are wanting. Hemorrhages are common; they are usually slight, but recur frequently.

This is a constitutional disease, due, the author believes, to some change in the blood, exactly what he was unprepared to say, but probably due to microörganisms. He thought that the disease described was nothing more than influenza, the same influenza which has been described so often, particularly by Graves. The disease has not been limited to the Mississippi Valley, for he had seen cases of it from all parts of the country.

The treatment is very simple. The system must be saturated with benzoate of sodium. Under this remedy the affection subsides in a few days or hours. If left to itself, it may continue for weeks and even months.

DR. WM. H. DALY had seen a number of cases similar to those described. He did not consider the condition as one of œdema, but rather as a subacute inflammatory condition of the mucous membrane. There was a sufficient number of these cases which had thin and superficial diphtheritic patches in various parts of the fauces to warrant him in considering the disease of a diphtheroid character. This view was confirmed by the subsequent occurrence of glandular enlargement in nearly all the cases.

DR. J. C. MULHALL, of St. Louis, confirmed the statements of Dr. Glasgow from his own experience with the disease in St. Louis, and reported a case in which the affection had recurred three times.

DR. S. H. CHAPMAN, of New Haven, had seen cases similar to those reported, but agreed with Dr. Daly that they were rather of a diphtheritic character. In one case the disease attacked a child of seventeen months. In the same family was a boy, nine years of age, with well-marked diphtheria. The first thing noted in the case of the child was a dense swelling of the submaxillary gland. There was great prostration, and some fever, 101°–102°. The swelling increased until it extended from the jaw to the clavicles. There was hoarseness and difficulty of breathing, which daily increased. By the seventh day it had increased so much that deep incisions were made into the gland, but no pus was found. A tube was then inserted into the larynx, and allowed to remain four days; the child during this time was kept alive by rectal alimentation. At the end of thirteen days the swelling began to diminish. The knife was again used, and a quantity of pus discharged. The child recovered.

DR. C. E. SAJOUS, of Philadelphia, referred to a case of this disease which occurred in a young man living on a farm in New Jersey, twenty miles from any neighbors, and who had not been exposed to diphtheria. The throat presented small white patches, resembling the yellowish leathery membrane seen in diphtheria. Slight œdema of the soft palate was also present. The temperature was high through the entire course of the disease. There was incessant pain in the back and in one limb. After trying a number of remedies, he was placed upon benzoate of sodium.

DR. GLASGOW remarked that he had, at first, regarded these cases as diphtheritic. In these cases the membrane is adherent. It can be torn away, but a bleeding spot is left. Applications made it worse. If left to itself, it gradually grows thinner and thinner, until it resembles a white pearly patch. Diphtheritic membrane does not pursue such a course. The glandular enlargements always occur, even when there is no exudation. He did not think that any one would assert that this œdema was diphtheria.

DR. W. H. DALY, of Pittsburg, then made some remarks based upon a few observations of the

INTIMATE RELATIONS OF CHRONIC DISEASE OF THE UPPER AIR TRACT AND NEURASTHENIA.

His experience had led him to believe that there was an intimate relation between conditions of the intranasal cavities and neurasthenia in some of its forms. This view was based upon the study of twenty-five cases. In these cases removal of the nasal trouble was followed by relief of the neurasthenic condition, no special treatment being directed to the general condition.

DR. J. O. ROE said that most of the members had seen many such cases, and they illustrate the effect that a constant local irritation will have upon the system. A constant nagging of a local irritant will sooner or later produce a depressed condition of the system.

DR. F. W. HINKEL, of Buffalo, remarked that before we could admit that neurasthenic condition could be the result of any nasal lesion as the sole cause, a careful analysis of all the constitutional conditions would be required.

DR. S.W. LANGMAID, of Boston, thought that often the nasal trouble was the result of the neurasthenia. It often happens that operative interference fails to relieve the nasal condition because neurasthenia is not cured.

DR. SAJOUS was inclined to support rather vigorously the view of Dr. Daly. In a number of cases he had observed that there were fluctuations in the nervous condition according as the local disease improved or became worse. In one case of neurasthenia associated with deviated septum, correction of the displacement was followed by improvement in the nervous condition. The operation, however, failed to be permanent, and with a return of the deviation the neurasthenic condition recurred, to disappear again with a more thorough operation upon the septum.

AFTERNOON SESSION.

DR. JOHN N. MACKENZIE read a paper on

SOME POINTS IN THE PATHOLOGY AND TREATMENT OF DISEASES OF THE NASAL PHARYNX.

The following conclusions were presented:

1. The nasal pharynx is in quite a large proportion of individuals exceedingly sensitive to reflex-producing stimulation.

2. The areas chiefly involved are the posterior portions of the turbinated erectile tissue, and various points along the upper and posterior portions of the nasal pharynx.

3. In consequence of this extreme sensitiveness, a local pathological process which in many persons would give rise to no reflex neuro-vascular changes may awaken a host of neurotic phenomena referable not only to the region primarily involved, but also to other and even remote organs of the body. These may include cough, asthma, and various neuralgic affections; or the local structural lesion may be the starting-point of various sympathetic affections of the respiratory tract.

4. That these classes of naso-pharyngeal neuroses are explicable on the same general principles laid down in

the article on neuroses of the nose, and the pathology of the nasal and post-nasal affections is, therefore, one and the same.

5. That the treatment should be carried out according to the general directions laid down in the article just mentioned.

6. That when morbid processes originate in the pharyngeal tonsil, attention should not be directed to the bursa alone, but an endeavor should be made to extirpate the tonsil as far as possible in its entirety.

7. That while a favorable prognosis cannot be safely predicted by treatment of the bursa alone, extirpation of the pharyngeal tonsil often affords a most favorable prospect in long-standing cases of post-nasal trouble.

DR. D. BRYSON DELAVAN then presented some

OBSERVATIONS UPON THE CONDITION KNOWN AS ADENOID HYPERTROPHY AT THE VAULT OF THE PHARYNX, AND THE METHODS USED FOR ITS REMOVAL.

A case was described in which with each acute attack of catarrhal trouble there would be enlargement of the adenoid tissue of the vault of the pharynx, forming a large tumor. When the attack passed away the hypertrophy disappeared. The author then referred to the methods of operation and the accidents which might occur. As the operation was attended with considerable pain he suggested the employment of anæsthesia. He had in a number of cases employed chloroform with satisfactory results, the object being to avoid the profuse mucoid secretion which is apt to follow the use of ether. Where chloroform is used the operation is performed with the patient on his back.

DR. F. H. HOOPER, of Boston, reported a case of a young lady who came to him with acute coryza and in whom he found a large-sized adenoid of the vault. After the attack subsided, the adenoid almost entirely disappeared. In order to avoid error, the post-nasal probe should be always used. With it conditions not apparent to the eye may be recognized. He had never seen serious hemorrhage follow operations for the removal of the tissue. In operating he first removes all that is possible with the post-nasal forceps and completes the removal with the finger-nail. He had never used chloroform. The amount of secretion after the use of chloroform varies very much in different cases.

DR. HARRISON ALLEN, of Philadelphia, advocated the use of the finger as a means of detecting these post-nasal affections. To examine the case thoroughly requires the use of an anæsthetic. In the treatment of adenoid hypertrophy, it is better to remove all the diseased tissue at one sitting under ether than to remove it in portions at different times.

DR. J. C. MULHALL held that for practical purposes the pathology of the pharyngeal tonsil was exactly the same as that of the faucial tonsil. In operating, he had applied cocaine thoroughly to the pharyngeal wall and soft palate to avoid the disagreeable sensation caused by the scraping of the forceps against the healthy pharyngeal wall, and had succeeded very well.

DR. F. I. KNIGHT related a case of acute hypertrophy of the faucial tonsil in which the surgeon performed tracheotomy preparatory to removing the tumor. When he came to operate he found that the growth had disappeared.

DR. WILLIAM E. CASSELBURG, of Chicago, referred to the importance of thoroughly eradicating these growths. In two cases in which portions of the mass had been left, the reflex symptoms, while greatly lessened, continued to recur. In two cases he had attempted to use the mirror during operation. To do this he pulled the soft palate forward by two rubber bands, passing through each nostril. In one case he succeeded to a certain extent, but in the other failed. This procedure, however, greatly facilitated the operation. In order to prevent the passage of blood into the larynx he was in the habit of bending the head forward at intervals in order to allow the escape of the blood.

DR. J. N. MACKENZIE, as a rule, operates without anæsthesia, removing a portion of the mass every day or every other day, continuing the operation for a week or ten days. He had seen very little pain from the operation. There is one point in regard to the nature of this so-called adenoid. He had examined a number of these growths under the microscope and they do not differ from papillomatous growths. There is also in addition a true adenoid growth; this is more difficult of removal than the former.

DR. F. H. HOOPER read a paper on

EXPERIMENTAL METHODS OF STUDYING THE ACTIONS OF THE INTRINSIC MUSCLES OF THE LARYNX.

He exhibited the apparatus which he had employed in studying the effect of stimulation upon the internal thyro-arytenoid, the lateral crico-arytenoid, and posterior crico-arytenoid muscles. The larynx of a dog is quickly excised, the mucous membrane removed, and the muscles subjected to electrical stimulation.

DR. F. I. KNIGHT then read a paper on

DYSPHONIA SPASTICA.

He briefly reported the four cases of this affection which he had seen in the last seven years. He regarded the condition as rare; there is probably a spasmodic action of the muscles of phonation, or respiration, or both, giving rise to a high-pitched, jerking voice. The prognosis is unfavorable. The object of the paper was to elicit reports of other cases.

DR. G. W. MAJOR had seen one case of aphonia spastica and two cases of dysphonia spastica. In none of the cases was benefit obtained by treatment.

DR. S. W. LANGMAID had reported one case in which treatment was unsuccessful. The patient, when he had to use his voice, prescribed for himself a little whiskey, and this answered temporarily. There seems to be no change in the voice since the affection first came on, fifteen years ago.

DR. DELAVAN said that in one case coming under his observation the patient was able to talk tolerably well after fortifying himself with a stimulant. This patient seemed to improve under local treatment to the larynx and vocal training, but the treatment could not be continued.

DR. C. E. BEAN, of St. Paul, had seen one case two years ago. Various methods of treatment had been employed without benefit. The voice is now the same as at the commencement.

Dr. Rufus P. Lincoln, of New York, read a paper on

RECURRENT LARYNGEAL GROWTH.

The patient had come under the care of the late Dr. Elsberg, twenty-four years ago. Dr. Elsberg first operated by the intro-laryngeal method, but could not remove the growth. Twenty-two years ago he did laryngotomy and removed the growth. The microscopical examination made at that time was unsatisfactory. There was no further trouble until a short time ago, when the growth recurred. Dr. Lincoln recently removed the tumor, which on microscopical examination proved to be a papilloma.

NEW YORK ACADEMY OF MEDICINE.

Section in Laryngology and Rhinology.

Stated Meeting, March 26, 1889.

C. C. Rice, M.D., Chairman.

Dr. T. W. Corwin, of Newark, N. J., presented a case of

HYPEROSTOSIS OF THE FACIAL BONES INVOLVING BONY OCCLUSION OF THE ANTERIOR NARES.

The literature of such bony occlusion is very scanty. Nevertheless, considerable attention has been paid to this subject recently in connection with cases reported by Drs. Potter, Hubbell, Pomeroy, Jarvis, C. M. Knight, Weir, and others. In all, about twenty cases have been collated. The majority of these have affected only the posterior nasal orifices.

The two cases reported by Dr. Jarvis are the only ones involving the anterior portions of the nasal fossæ. The author has carefully examined the literature of the subject by English-speaking observers and finds no other instances of anterior bony occlusion of this type.

Bony occlusions have been classified according to their origin as septal, turbinal, and palatal. The case here reported appears to be of turbinate origin. The lesion involves both sides symmetrically and has the following history:

Mary A. B., nativity United States, single. She was referred to Dr. Corwin for examination about February 1, 1889, by Dr. T. Y. Sutphen, Surgeon to the Eye and Eye Department of St. Michael's Hospital, Newark, N. J., who had treated her for acute catarrh of the left lachrymal duct, epiphora, etc., with relief. She presented a peculiar physiognomy. The frontal, malar and inferior maxillary bones were prominent, while the nose was but slightly developed and the central portion of the face had but little fulness. The mouth was constantly held slightly open. The features were symmetrical, excepting greater depth of the right eyeball. Examination of the anterior nares revealed complete occlusion upon the left side and nearly complete occlusion of the right side. The vestibules were normal. Slightly back of the vestibule of the left side, at the normal site of the inferior turbinate, the canal was closed by a wall springing from the outer side which curved inward and slightly backward and met the septum at an acute angle. Above, this led to a closed canal, along which a small probe was admitted to the pharnyx over a bony mass about one and three-quarters inches in length.

Upon the right side the canal was much larger and corresponded to the normal condition of the organ above the inferior turbinate. This canal was pervious and permitted difficult respiration with râles. The probe traced the obstruction to the same extent backward as upon the left side and gave it the same characters. The mouth is normal. There is no labial hypertrophy. The palatal arch is not unusually high. The upper teeth are mostly absent and are replaced by an artificial set. The inferior maxilla is very large in every direction and gives a massive appearance. It is about three-fourths of an inch in thickness. The velum palati approximates considerably to the post-laryngeal wall. On rhinoscopic examination, the post-nasal space is short from front to back. Only the upper half of the choanæ were seen by the mirror, and these were normal.

By palpation the palate bones presented no deviation, but the Eustachian tubes were large and completely ossified.

No other anomalies were found excepting retraction of the lower part of the sternum. The heart and lungs were normal. There is general chronic pharyngitis and naso-pharyngitis.

Sight normal. Hearing good. Olfaction unimpaired. Nasal respiration was but fractional and permitted upon the right side only. There was constant mouth breathing, frequent sneezing, and during sleep loud snoring. The voice is husky, with loss of the upper tones and of nasal resonance.

Excepting two sisters, the remainder of the family of nine members died during her childhood. No details can be obtained. Both sisters are healthy.

Patient knows of no illnesses in childhood, excepting measles and whooping-cough, but, as far as her memory extends, she has had difficulty in breathing through the nose, which has been progressive. Suckling is said to have been normal.

She has been much subject to colds, had pneumonia when thirteen years of age, and again a year later; some years afterward a severe bronchitis, and a third attack of pneumonia five years ago.

Treatment.—Partial and temporary relief was had from cocaine and Dobell's solution. About May 1st she was operated upon by Dr. Rice at his clinic. With the electro-trephine a channel of one-fourth inch diameter was made through the bone upon the right side. No irritation followed.

Dr. Knight said that his own observation has been in connection with obstruction in the posterior nares, which seems to be of a different character from this. His cases were due to thickening and distortion of the palatal bone. The treatment in one was by the electric trephine, and was successful as regards obstruction of respiration. There is one feature with regard to this case which struck him as remarkable, and that is the very slight impairment of function associated with this deformity, which we should naturally expect to be considerable in such cases. There was but little disturbance of any of the functions, except the sense of smell, in his cases. There was diminished hearing distance in the ear on the side of the affected nostril, but breathing was free enough through the other nostril.

Dr. S. T. Armstrong then read a paper on

LARYNGEAL VERTIGO.

(See p. 624.)

DR. L. C. GRAY said that he thought this the best paper upon the subject of laryngeal vertigo which he had ever had the pleasure of hearing or reading. The first case upon this side of the water was, he believed, reported by himself. This was some years ago, and he had not seen a case since. He did not know that there were so many cases upon record. But the term vertigo seemed to him a misnomer, for, as it is used by the American and English authors, it does not mean a loss of consciousness, but only a faintness, a dizziness, a swimming, a seeming loss of equilibrium, without any more than the faintest shadow of an obscuration of consciousness.

There are many important clinical reasons why we should keep the term vertigo distinct in its meaning from anything that implies a loss of consciousness. He had suggested the term epilepsy because the loss of consciousness in these cases is a genuine one, and because, in some patients, the loss of consciousness has been attended with tonic or clonic convulsions. His experience is, that when a person gets into the habit of losing consciousness, he is very apt to keep up the habit, and it is very difficult to break him of it, unless the loss of consciousness is a mere faint, as it occurs in some women, or unless it is associated with migraine, or some organic visceral disease. Whenever losses of consciousness are set up by disease of the central or peripheral nervous structure, whether that disease be organic or functional in its nature, that loss of consciousness is, so far as our present knowledge goes, of the nature of what we call by the generic name of epilepsy. It has not been established yet that the removal of an irritating cause will break up the epileptic habit, and it has not been proven that the removal of the irritating causes in cases of this kind will have any more effect. Temporary cessation of losses of consciousness does not, by any means, imply abolition of them, for they may be absent for months, or even years, and then return in full vigor. The word syncope has been suggested as a better term, but this is a great deal more than a syncope. It is a full loss of consciousness.

The case that he reported some years ago, that Dr. Armstrong referred to in his paper, still has occasional attacks, at least he did about a year ago when Dr. Gray last saw him.

DR. W. R. BIRDSALL had listened with a great deal of interest to the paper, and the main question in his mind, the one he would like to ask is, How are these cases related to the so-called laryngeal crises of locomotor ataxia? The cases of so-called larygeal vertigo are so few that he had his doubts where we ought to classify them.

A case came to mind that he observed several years ago, in which a patient affected with posterior spinal sclerosis related a distinct history of so-called laryngeal crises; but of such a violent type that he lost consciousness for a moment. He was seen by him at Manhattan Hospital, and was referred to the throat department, where they found a slight enlargement upon one of the vocal cords, which disappeared under treatment after a few weeks, and for a long period he had no more of these attacks. Then he came to him again, reporting that he had had an attack, and attempting to look at his larynx provoked one of his attacks, the only attack of so-called laryngeal vertigo he had ever seen; he never cared to repeat the experiment with him. The man apparently fainted, said that for a moment he lost consciousness. His face became very blue, there was evidently a good deal of laryngeal spasm at first. The description of these cases of laryngeal vertigo seemed to him very much like those of laryngeal crises or spasms which occur in locomotor ataxia.

Dr. Gray's way of looking at the subject is a plausible one. A certain number of these cases may possibly be epileptic, yet we know how readily loss of consciousness is produced. It seemed to him that the future may show that we have quite a variety of causes and conditions to account for such attacks.

DR. C. L. DANA said that the paper suggested to him much the same observations as those made by Dr. Birdsall, viz., the resemblance of these cases to the laryngeal crises of locomotor ataxia. He had recently had a patient with normal heart who suffered from such crises, during which there was great dyspnœa, rapid heart action, and disturbance of consciousness, and other evidence of involvement in the vagus and spinal accessory nerves. If these nerves were functionally and organically affected in locomotor ataxia, they might be also affected in other morbid conditions.

DR. S. T. ARMSTRONG said that, in regard to the remarks of Dr. Birdsall, Ferrial has made the same comparison of the laryngeal symptoms. The fact that in laryngeal vertigo nearly all the cases reported, except the one by Dr. Gray, have recovered, would show that they are simply temporary impairments of the function of the superior laryngeal nerve. Very possibly, it is the same fundamental principle at issue in each case. There is certainly, in the laryngeal crises, in tabes dorsalis, a much more powerful impression created, and symptoms of longer duration, than in laryngeal vertigo.

NEWS ITEMS.

Risks of an Outbreak of Yellow Fever this Summer.—Dr. Jerome Cochran, State Health Officer of Alabama, has just returned from an extensive trip through South Florida and Havana, made to investigate the yellow fever situation and obtain information as to the prospects of a fresh outbreak of the disease during the approaching summer. In an interview with the Associated Press as to the result of his trip, Dr. Cochran said:

"I am satisfied there has been no yellow fever in Jacksonville, Fla., since January last. A death from yellow fever was officially reported at Sanford, Fla., about the middle of April, but although six weeks have elapsed there have been no subsequent cases there. I visited the towns on the Manatee River, being specially interested in the Manatee country, because the people ship their farm and garden products to Mobile, and get their supplies from Mobile. I found no yellow fever in any of the Manatee towns. A suspicious case was reported at Palmetto a few weeks ago, but I saw the patient with the health officer of Florida, and we found that it was not yellow fever. The last case at Palmetto, which is one of the Manatee towns, occurred last November.

"I visited Havana and found very little yellow fever there, the average being fifteen or twenty cases a week, which is unusually light, considering that this is the epidemic season in Havana. Everywhere in South Florida and Cuba the health of the people was reported to be exceptionally good. The whole country is suffering from

drought, no rain having fallen in many weeks. The vegetable crops have been considerably damaged, and the people fear the orange crop will be cut off, but the health of the people is unusually good."

When asked what he thought about the prospects for an outbreak of fever this summer, Dr. Cochran said:

"I am entirely satisfied that there has been no yellow fever in Florida except the one solitary case reported at Sanford, since last January. There has been a very general feeling of apprehension among the health authorities of the Southern States that yellow fever might have lived through the mild winter in Florida, and might break out afresh during this summer. It is impossible to make any confident prediction, but I am inclined to believe that there will not be any fresh outbreak in Florida this year, unless there is a fresh importation of the disease."

Vital Statistics and the next Census.—Hon. Robert P. Porter, Superintendent of Census, has issued the following card to the medical profession:

"The various medical associations and the medical profession will be glad to learn that Dr. John S. Billings, Surgeon U. S. Army, has consented to take charge of the Report on the Mortality and Vital Statistics of the United States as returned by the Eleventh Census.

"As the United States has no system of registration of vital statistics, such as is relied upon by other civilized nations for the purpose of ascertaining the actual movement of population, our census affords the only opportunity of obtaining near an approximate estimate of the birth and death rates of much the larger part of the country, which is entirely unprovided with any satisfactory system of State and municipal registration. In view of this, the Census Office this year will issue to the medical profession throughout the country 'Physician's Registers' for the purpose of obtaining more accurate returns of deaths than it is possible for the enumerators to make. It is earnestly hoped that physicians in every part of the country will coöperate with the Census Office in this important work. The record should be kept from June 1, 1889, to May 31, 1890. Nearly 26,000 of these registration books were filled up and returned to the office in 1880, and nearly all of them used for statistical purposes. It is hoped that double this number will be obtained for the Eleventh Census.

"Physicians not receiving Registers can obtain them by sending their names and addresses to the Census Office, and, with the Register, an official envelope, which requires no stamp, will be provided for their return to Washington.

"If all medical and surgical practitioners throughout the country will lend their aid, the mortality and vital statistics of the Eleventh Census will be more comprehensive and complete than they have ever been. Every physician should take a personal pride in having this report as full and accurate as it is possible to make it.

"It is promised that all information obtained through this source shall be held strictly confidential."

Canned Meats.—*The American Grocer* referred some recently reported cases of supposed poisoning by canned meats, which occurred in Elizabeth, Plainfield, and Kearney, New Jersey, to Dr. W. K. Newton, M.D., Food Commissioner of the State, for investigation, and he reports that the Kearney and Elizabeth cases, 19 in all, were poisoned by putrefactive changes in corned beef which had not been canned, and the two Plainfield cases were caused by canned salmon which emitted a hissing sound when the knife cut through the tin, showing that its conrents were imperfectly preserved, and that fermentation had started.

The Popularity of Cremation.—Since the report of the Society for Cremation up to the first of last August, there have been 998 cremations in Italy, 287 in America, 554 in Gotha, 16 in England, 39 in Sweden, 7 in France, and 1 in Denmark, making a total of 1902.—*Revue Gén. de Clin. et de Thêr.*, May 2, 1889.

Corrigendum.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 28 TO JUNE 3, 1889.

By direction of the Secretary of War, JOHN S. BILLINGS, *Major and Surgeon,* is authorized to make, in connection with his duties as Supervisor of Mortality and Vital Statistics of the Eleventh Census, such journeys as may be ordered by the Superintendent of the Census, provided that, in each case, the approval of the Surgeon-General shall be obtained; and provided further, that the journeys shall involve no charge against the fund for transportation of the Army.—Par. 12, *S. O. 122, A. G. O.*, May 27, 1889.

By direction of the Secretary of War, leave of absence for six months, on account of sickness, is granted to PAUL R. BROWN, *Captain and Assistant Surgeon.*——Par. 3, *S. O. 122, A. G. O.*, May 27, 1889.

The resignation of GEORGE F. WILSON, *Captain and Assistant Surgeon,* was accepted by the President, and took effect May 31, 1889.

FISHER, WALTER W. R., *Captain and Assistant Surgeon.*—The leave of absence for one month, granted by S. O. No. 30, *c. s.*, Department of California, is extended fifteen days.—Par. 3, *S. O. 37, Headquarters Division of the Pacific, San Francisco, California,* May 22, 1889.

By direction of the Acting Secretary of War, JAMES D. GLENNAN, *First Lieutenant and Assistant Surgeon,* is relieved from duty at Willett's Point, New York, to take effect June 1, 1889, and will proceed to Fort Riley, Kansas.—Par. 5, *S. O. 121, A. G. O*, May 5, 1889.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING MAY 25, 1889.

HUTTON, W. H. H., *Surgeon.*—To proceed to New Orleans, Louisiana, and inspect unserviceable property, May 25, 1889.

PURVIANCE, GEORGE, *Surgeon.*—Detailed as Chairman of the Board of Examiners, May 22, 1889.

AUSTIN, H. W., *Surgeon.*—Detailed as a member of the Board of Examiners, May 22, 1889.

GODFREY JOHN, *Surgeon.*—Detailed as Recorder of the Board of Examiners, May 22, 1889.

GUITÉRAS, JOHN, *Passed Assistant Surgeon.*—Resignation accepted, by direction of the President, as tendered, to take effect April 30, 1889, May 11, 1889.

ARMSTRONG, S T., *Passed Assistant Surgeon.*—Granted leave of absence for thirty days, May 11, 1889.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

ORIGINAL LECTURES.

ARTHRECTOMY OF THE KNEE-JOINT.

A Clinical Lecture
delivered at the German Hospital, Philadelphia.

BY JOHN B. DEAVER, M.D.,
VISITING SURGEON TO THE HOSPITAL.

GENTLEMEN: The patient I show you to-day, you will remember as the one I had the pleasure of presenting to you some time since, when I pronounced it a case of hysterical trouble of the knee-joint. In making this statement I was influenced somewhat by the fact that the patient had been treated for several weeks in one of our largest hospitals, being under the care of one of our best known surgeons for this supposed trouble. Since the day I last presented her in this clinic, having had an opportunity of seeing her at different times and in different positions, I have been struck by the manner in which she gets around, believing that the pain of which she complains, and which she refers to the knee, not to be feigned, but actual, and caused by some organic trouble of the joint.

A few days ago, upon making a more critical examination of the joint by palpation, manipulation, and measurements, I satisfied myself that there was intra-articular disease. I based my opinion upon the following points: first, the contour of the affected joint, particularly above and below and upon either side of the tendo-patella, when compared with that of the opposite limb, will be seen to present a slight difference in favor of this joint. The two lower of these points, those upon either side of the tendo-patella, and which I now demonstrate to you, should not be convex prominences, as they are here, but depressions, as upon the opposite limb, the latter being the normal condition of the parts. Palpation of these points elicits a sense of elasticity, due perhaps to the presence of pus; but I think not, as there would be more disorganization of the joint in addition to the constitutional manifestation of the presence of this fluid. I believe these prominences to be due to a thickened synovial membrane, probably the site of granulation tissue, and to the relaxation of the capsular ligament and the fibrous expansion of the quadratus extensor femoris, which surrounds the joint, consequent upon the intra-articular pressure. Again, as these points are rendered more prominent by strongly flexing the knee, and are not made to disappear by strongly extending the limb, also as the skin and superficial fascia move freely over them, I am convinced that they are intra-articular. By next directing our attention to the contour of the part of the joint immediately above the patella over the site of the quadratus femoris bursa, we find it more prominent than that of the same part of the corresponding limb.

I will now subject the joint to forcible flexion, which you will notice causes the patient considerable pain. In executing these manipulations I meet with a resistance, which to my mind is greater than would be occasioned by simply the straining efforts of the patient, and due, therefore, to the presence of intra-articular irritation. I will now attempt to elicit lateral motion by grasping the thigh strongly with one hand and the leg with the other hand and move them alternately from side to side; this manipulation proves to be negative, showing that the ligaments of the joint, especially the lateral, are but little, if any, affected. By placing the limb in the extended position and grasping the patella, I am able to move it more freely than I am the patella of the corresponding joint, it communicating to my sense of touch a feeling as though it were resting upon a cushion. With the limb in the same position, by making pressure upon the patella, also by grasping the leg and forcing the head of the tibia against the condyloid extremity of the femur, in both instances crowding, as it were, the parietal and the visceral layers of the synovial membrane, I succeed in provoking a very much greater amount of pain than I am able to do by subjecting the opposing limb to the same manipulation. Again, by comparing the measurements of the affected joint, particularly at the points to which I have referred, with those of the joint of the corresponding side, the difference is strongly in favor of the affected side. My diagnosis, therefore, is chronic inflammation of the synovial membrane, particularly of that part lining the anterior part of the joint. I do not think there is any involvement of the articular cartilages; but this we will demonstrate after having opened the joint.

The patient has been, both here and in the hospital where she was before being admitted to this, subjected to the best possible treatment, both constitutional and local, for her trouble. The constitutional treatment consisted of good nutritious diet and the administration of tonics, chiefly iron, quinine, arsenic, strychnia, and cod-liver oil; and the local treatment, of counter-irritation over the joint in the shape of the tincture of iodine, of small blisters, of the application of an ointment composed of equal parts each of mercury and belladonna, which I have upon previous occasions recommended to you most highly in the chronic inflammations of the tissues of the joints. Her limb has also had the benefit of absolute rest, it having been incased in a plaster-of-Paris dressing for several weeks consecutively. You will see, therefore, that this patient has been given the benefit of every doubt, the treatment to which she has been subjected extending over several weeks, and, notwithstanding this, her trouble is increasing. As we have demonstrated actual physical trouble in this joint, I feel I am justified in exploring the joint by opening it upon the inside of the tendo-patella over one of the two most prominent points to which I have referred, when I can examine it,

both by inspection and by my finger, thus enabling me to determine whether to proceed further or not.

In the event that I find the disease limited to the synovial membrane, with perhaps invasion of the cartilages, I will perform the operation known as arthrectomy, and which, to my knowledge, has been done but once in Philadelphia, and that by Professor John Ashhurst, at the Children's Hospital, in October last. Arthrectomy means removal of the soft tissues of the joint without disturbing the bones. When we make a section from either the lower end of the femur or the head of the tibia, or both, we do an excision and not an arthrectomy.

Arthrectomy was first performed by Wright, of Manchester, in 1881. The operation is done more by English surgeons than any other, yet both the German and French surgeons do it. The advantages claimed for this operation over excision are, that the length of the limb is not interfered with, there being no risk of consecutive shortening; also, no danger of axial deformity—by that I mean the leg turning in while the thigh rolls out.

The limb having been carefully prepared for the operation, we will, of course, adhere most strictly to antisepsis, being extremely careful not to overlook a single point in carrying out this treatment, as I firmly believe that operations of this character are only justifiable when done under the most strict antiseptic precautions. I will first apply this rubber tube, which has been lying in the sublimate solution for some time, around the patient's thigh, a short distance above the knee; the object of this is to render the operation bloodless, which is very important in an operation of this kind, as it will enable me to make to the best possible advantage the dissection for the removal of the entire synovial membrane of the knee, or a part of it (in the event we find the disease confined simply to it). I will first explore the joint over the inner of the two prominences situated on either side of the patellar tendon, by carrying an incision through the soft parts. I am now able to expose the synovial membrane, which I find is discolored, thickened, and covered by granulation; I will next introduce my finger into the joint through this opening, when I am able to satisfy myself that the synovial membrane lining the anterior part of the joint is likewise diseased. I will, therefore, proceed to open the entire joint by carrying an incision from a point posterior to the middle of the internal condyle over the front of the joint, and between the lower end of the patella and the tuberosity of the tibia, to a point behind and below the middle of the external condyle, this incision going into the joint and passing through the one first made for the purpose of exploration. I will next dissect and reflect upward the large flap, including the skin, superficial fascia, the expanded tendon of the quadriceps extensor, the capsular ligament, the patella, and the parietal layer of the synovial membrane lining the joint upon this aspect, when I am able to demonstrate to you the appearance of the diseased synovial membrane. To expose the synovial lining of the bursa beneath the tendon of the quadriceps extensor femoris muscle, I will carry two incisions upward upon either side of the patella through the fibrous capsule of the joint and the capsular ligament, when I find this portion of the synovial membrane more diseased than that of any other.

It remains for me to examine the synovial membrane lining the articular extremities of the bones, and the back of the joint; to expose this portion of the membrane, I will place the limb in the position of strong flexion, when you will see that the synovial membrane covering the articular extremities of the bone, and lining the back part of the cavity of the joint, presents an entirely different appearance from that which I have already exposed, and to which I have called your attention. This portion of the membrane is perfectly normal, therefore we shall leave it alone, and go back and confine the remaining part of our manipulation to the removal of the membrane diseased; this dissection I will now make, using a pair of dissecting forceps and a knife, substituting the latter occasionally by scissors curved on the back. The visceral layer of the synovial membrane along the lateral borders of the patella and the upper edge of the condyles of the femur, presenting the same appearance as that which I have removed, calls also for removal; this I will do with the curette in this manner: All of the diseased tissue having been removed, it remains for me, after the removal of the rubber tube, to arrest all bleeding, thoroughly drain the joint, close the wound, dress the limb, and place it in a fixed position.

The rubber tube having been removed, you will notice that there is some bleeding, this we control by tying the bleeding vessels with catgut ligatures. As the question of drainage is so important, I will place a large rubber tube through the joint and in front; I will also introduce two tubes, one upon either side, into the bursa patella; I will now close the joint by stitching, first the tendo-patella, and secondly the capsular ligament and the fibrous expansion of the quadriceps extensor, with interrupted catgut sutures; I will close the wound in the soft parts with interrupted silver wire sutures.

Now notice, please, that after having closed the wound thoroughly, I am able to irrigate the joint perfectly through these tubes, and you will also notice that the fluid comes out perfectly clear, showing that there is no bleeding going on within the joint. I will now dress the wound with the ordinary antiseptic dressings, and apply a long posterior splint to the limb. It will be important for us to keep the limb well supported posteriorly for some time, for the purpose of preventing any tendency to consecutive flexion, one of the objections urged against this operation by French surgeons, but this I may say occurs sometimes after excision, if we are not careful to support the limb until some time has elapsed after the union is apparently perfect.

ORIGINAL ARTICLES.

CAN PNEUMONIA BE CUT SHORT BY ANTIPYRIN?

By H. G. BEYER, M.D., Ph.D., M.R.C.S. (Lond.),
P. A. SURGEON U. S. NAVY.

An article upon this subject appeared in the *Lancet* of April 13, written by Mr. E. H. Counsell, and was answered by Mr. R. Sisley, M.B., M.R.C.P., through the columns of the same journal April 27. It attracted my attention, as I had previously been much interested in antipyrin, and last year had two patients ill with pneumonia which were treated with this drug, with what I considered excellent results. I have been waiting since for larger opportunities

and more extended experience before calling attention to these cases. The question, however, having now been brought up in the *Lancet*, and in view of the importance of the subject, I have concluded to add whatever evidence I have been able to draw from this limited experience.

The two cases of pneumonia came under my observation and care while serving as senior assistant surgeon on board the ill-fated U. S. S. "Trenton" during her passage from New York to Porto Grande, Cape de Verde Islands, in the month of February, 1888. The first case, indeed, seemed to me of so remarkable a character, that I copied a few rough notes on it from the ship's medical journal into my private note-book, which, however, I am sorry to say, I failed to do of the second case, not less noteworthy. The history of this case is briefly as follows:

CASE I.—John D., aged twenty-two years and two months, a native of Holland, always been well and giving a good family history, was admitted to the sick-list on the morning of February 2, 1888. (The "Trenton" left New York harbor the day before, February 1st.) He was taken with a severe rigor early that morning, and was feeling very ill and much depressed in spirits. Physical examination at the time revealed nothing beyond the presence, over the lower lobe of the right lung, of a few moist râles with some pleuritic friction. The temperature was 100.4° F., pulse 96, full and strong; in the evening of the same day the temperature went up to 103°; pulse was 120 per minute; there was great restlessness, headache, and complete anorexia.

February 3. Physical examination revealcd the presence of distinct and unmistakable crepitant râles over entire lower lobe of right lung; temperature 102.2° in the morning, 102.5° in the evening; respirations 30 per minute, shallow in character; slight hacking cough, with rusty-colored sputa; pulse 120, hard and strong in character, tongue thickly coated with brownish-white fur, somewhat fissured, dry, and unsteady; wears an oil-silk jacket fitted to his chest.

4th. Temperature 101.8° in the morning; 102.1° in the evening; principal diet milk; received no solid food.

5th, or the fourth day after admission, crepitant râles were discovered on the left side of the chest, especially abundant over the posterior aspect below the angle of the scapula; temperature 103.8° in the morning, 104.2° in the evening; has delirium with hallucinations, and a regular watch is being kept over him constantly; tried to leave his cot several times; was given ten grains of quinia sulphate in some whiskey; pulse is very frequent, weak, and small.

6th. Temperature 101.5°. Patient is very much worse this morning; pulse very frequent and small, with difficulty felt at the wrist; apparently in a condition of arterial ischæmia and corresponding venous congestion, owing to the sudden appearance of double pneumonia and consequent obstruction to the pulmonary circulation; delirium of the low muttering type, with hallucinations kept up more or less all day long. In the evening temperature was 104°; pulse very frequent, feeble, and fluttering; heart's action irregular and intermittent; picking about his clothes constantly; the face presents a deeply congested, lips a bluish, look. His general condition on that evening was so critical that a collapse seemed imminent. A hypodermatic injection of one-third grain of morphine was administered on account of the great restlessness and delirium present; half an hour later no change in the condition. At 10.30 P.M., or about half an hour after giving the morphine, a full dose of thirty grains of antipyrin was administered by the mouth. Twenty minutes later he became quieter, and one hour after taking the antipyrin he slept quietly, and continued so all the night for the first time since the beginning of his illness, at the same time perspiring so profusely that all his bed-clothes, mattress, and cot were found to be wet the next morning and had to be changed. He awoke feeling much better, and for the first time since his admission seemed to take nourishment with relish.

7th. His temperature in the morning was 100°; pulse 92 per minute, stronger than on the previous evening; heart's action regular; crepitant râles still marked toward the end of each inspiratory act over areas indicated above, but especially over the left side of the chest. On the evening of the same day his temperature was but 0.5° above what it had been in the morning; appears brighter, having felt comfortable all day; taken and enjoyed every regular ration of milk which was offered him.

On the following morning he was found to be still better; his sleep had been undisturbed and refreshing without the use of anodynes; has received no medicine of any kind since the antipyrin was administered; temperature 99.5°; took some solid food to-day; temperature in the evening 99°. From this time forward the temperature never rose again above the normal. This patient began to leave his cot on February 10th, or on the ninth day of the disease, and convalescence was rapid, passing on uninterruptedly to complete recovery.

CASE II., so far as I am able to recollect, was quite similar to the first, excepting that it was much more mild in its onset, and the diagnosis could not be established until the fourth day of the disease. This having been done to the satisfaction of Medical Inspector Adrian Hudson and Assistant-Surgeon S. S. White, one-third of a grain of morphine was administered hypodermatically, followed afterward by thirty grains of antipyrin by the mouth, just as had been done in the first case. The result was practically the same, though, perhaps, not quite so striking as in the previous case, but recovery took place without further medication.

Whatever effect was produced by medication in the above two cases, we are bound to attribute to the combined influence of the morphine and antipyrin rather than to the latter drug alone. But the question is, Have we here sufficient evidence to show that any effect was produced by the drugs which were administered other than might have

occurred without the administration of either of them? Are we not rather led to expect, even without any special treatment, what occurred, for instance, in the first case, namely, the crisis on the fifth day, with profuse perspiration, as marking the beginning of convalescence in a typical case of pneumonia? Nor is the second case, although the crisis occurred on the fourth day, at all convincing in this respect.

While, then, we must admit all this, after carefully studying the two cases before us we confess frankly that a very strong belief has crept in upon us that, after all, the results produced in the above-mentioned cases were the immediate and direct effects of the drugs administered, urging us on very strongly to try the same things again under similar circumstances. Science, it is to be hoped, may help us out sometime in therapeutics, but that time seems to be as yet far off; we cannot afford to wait for it to come, and meanwhile stop altogether administering drugs simply because we are not in a position to do it on strictly scientific principles.

But let us try and study the conduct of the antipyrin administered in the above-mentioned cases a little more minutely, and we may, perhaps, succeed in learning something, after all, from its possible mode of action. In view of the fact that Case I. had passed into one of double pneumonia at the time of the administration of the antipyrin, the obstruction which was thereby offered to the pulmonary circulation probably had resulted in great weakness and partial enlargement of the right ventricle, with general engorgement of the venous side of the systemic circulation as well as of the portal circulation. Owing to this condition of things, the morphine injected hypodermatically and not producing the usual effects within half an hour, was probably not absorbed at all or very slowly, and did not get into the systemic circulation in sufficient quantity to produce the desired effect.

From the limited number of experiments which I made with antipyrin on the circulation, published in *The American Journal of the Medical Sciences*, 1885, I came to the conclusion that antipyrin is a heart-tonic, dilates the bloodvessels and at the same time produces no appreciably injurious influence on the blood. In the natural course of events the antipyrin, given by the stomach, probably reached the right ventricle first, having to pass through the lungs before arriving in the left ventricle and passing into the general circulation. If, now, we may assume that a tonic effect on the heart was produced by antipyrin in this case, and during its passage through the lungs a further dilatation of the pulmonary vessels, whereby the great venous congestion was relieved and the circulation equalized, we would have at least a physical explanation, not only accounting for the rapid subsequent absorption of the morphine, but also for the general amelioration produced in our patient, as set forth in the history of the case.

With regard to the experiments with antipyrin referred to, I, of course, do not wish to be understood as wanting to apply directly to man what was found to be true of animals only. Yet it must be admitted that our first, and perhaps most scientific indications for the use of drugs in man are derived from pharmacological experiments on the lower animals. In the opinion of the writer antipyrin would be more especially indicated during that stage of the pneumonic process during which we have great interference in the circulation, on account of its possessing the property of not only stimulating the heart but also of dilating the vessels at the same time.

Most of our ordinary heart-tonics, while they stimulate the heart's action, cause a simultaneous vascular contraction, and hence do not meet the exact requirements of the case.

Whatever effect was produced on the pneumonic process by the antipyrin in these two cases must, of course, be mere conjecture; if the pneumococcus is influenced unfavorably by it, laboratory experiments might suffice to show, but extended clinical experience would be necessary actually to prove it.

In conclusion, therefore, I would say, while these two cases prove nothing, they are, to say the least extremely suggestive.

LESIONS OF THE SACRAL AND LUMBAR PLEXUSES.

With Remarks on their Importance, and their Diagnosis, General and Localizing.[1]

BY CHARLES K. MILLS, M.D.,
PROFESSOR OF DISEASES OF THE MIND AND NERVOUS SYSTEM IN THE PHILADELPHIA POLYCLINIC; NEUROLOGIST TO THE PHILADELPHIA HOSPITAL.

THE purpose of the present paper is to show the importance and comparative frequency of lesions of the limb plexuses, to give some suggestions or rules for their recognition, and briefly to refer to questions connected with their surgical treatment. Gross lesions, not degenerations, will be considered; and so-called functional affections, such as neuralgias proper, will be treated of only as necessitated by a discussion of diagnosis. Some of the lesions of the limb plexuses or their cords or branches are common to all, as, for example, neuritis, neuromata, non-neural growths implicating nerves, aneurisms, abscesses, gunshot and other injuries. Other gross lesions have a special character owing to location: as rectal, ovarian or uterine lesions involving the

[1] Read before the Neurological Section of the New York Academy of Medicine, May 10, 1889.

sacral; vertebral caries and certain abscesses the lumbar, and dislocations of the shoulder or fracture of the clavicle, the brachial plexus. It will be impossible in the space to which this communication must be restricted to dwell at length upon fine points of localization; but specifically in a few instances and incidentally in others, localizing facts and rules will be given. Complicated as is the sensory and motor arrangement and distribution of these plexuses, thanks to the careful work of Mitchell, Paterson, Goodsir, Ferrier, Bert and Marcacci, Forgue and Lanagrace, Walsh, Putnam, Herringham, Ross, Thorburn, and a few others, we are now able to approach the subject of the localization of lesions of even particular cords of these plexuses and their nerve roots with increasing confidence.

LESIONS OF THE SACRAL PLEXUS.

The sacral plexus formed by the lumbo-sacral cord, the anterior divisions of the three superior sacral nerves, and a part of the fourth, rests largely upon the surface of the pyriformis muscle in the true pelvis; and a single glance shows how thoroughly, in accordance with its great function, it is protected both by its position and coverings.

It may be well to recall one or two well-known points in pelvic neural anatomy which may have some localizing value. The superior gluteal nerve, for instance, arises from the back part of the lumbo-sacral cord, and is the only nerve that springs from that important link between the lumbar and sacral plexuses; so that a lesion strictly limited to this cord would give sensory and motor impairment in the distribution of this nerve, as well as the symptoms resulting from interference with the functions of the lumbo-sacral cord itself. The muscular distribution of the superior gluteal is to the gluteus minimus and medius and tensor vagina femoris. The lowest of the intra-pelvic nerves are not connected with the sacral plexus at all. These are the branches of the fourth and fifth sacral nerve roots to the levator ani, sphincter ani, coccyx, and skin of these parts. A lesion may be so isolated as to affect only these extra-plexal pelvic nerves, or the plexus may occasionally be affected and these nerves escape.

The neurologist should know the landmarks for examining and palpating the sacral plexus and intra-pelvic nerves by the rectum, the chief of which are the great and lesser sacro-sciatic ligaments, the spine of the ischium, and the pyriformis muscle.

A few general statements with reference to lesions of the sacral plexus may serve to present the subject more clearly and comprehensively. A lesion of the sacral plexus in its entirety will strongly counterfeit a unilateral affection of the lumbo-sacral portion of the spinal cord from which the nerves of the plexus arise, or of the lower part of the cauda equina within the spinal canal. Bilateral lesions of the sacral plexuses so closely counterfeit lesions of the lumbo-sacral region of the spinal cord, or of the cauda equina, as to make the diagnosis sometimes exceedingly difficult; and in some cases of this kind the differentiation can be best made by proper local manipulation and examination by the rectum or vagina, or both. Lesions of single or several cords of this plexus, or of its nerve branches within the pelvic cavity, may counterfeit neuralgias of the nerves in either their intra- or extra-pelvic distribution; sciatica is a frequent diagnosis in these cases. Lesions of the sacral plexus or intra-pelvic nerves are not infrequently supposed to be disease of the uterus or ovaries, or their appendages and surroundings; and, on the other hand, disease and enlargements of these parts often involve the plexus.

Beside growths or other diseases of the uterus, ovaries, and their connected parts, the gross lesions which may affect the sacral plexus, or in which it may be implicated indirectly, are neuritis or nerve degeneration from pressure or bruising during labor, rectal disease, pelvic cellulitis and abscesses, pelvic or intra-pelvic tumors, particularly neuromata, osteomata, and osteo-sarcomata, gunshot wounds, and neuritis, unilateral or bilateral, of unknown cause.

Psoas abscess may follow such a course as to involve the sacral plexus, and, before taking up the special lesions of the plexus, I may dismiss this point with a few words. Psoas abscess tends often to follow an irregular or multiple course. The pus may pass down the sacrum; it may even leave the pelvis by the sciatic notch. Brodie[1] records a case in which the abscess descended from the loins and presented as a tumor in the groin. Suddenly the tumor disappeared, but later a large collection of matter was found in the posterior part of the limb, behind the little trochanter of the femur. Post-mortem examination showed that the abscess had taken the course of the common tendon of the psoas magnus and iliacus internus muscles to their insertion into the bone, afterward extending further backward below the inferior edge of the quadratus femoris. A number of cases have been recorded in which this complication has occurred. Thompson[2] has, for example, reported a case of psoas abscess which was supposed for months to be one of sciatica. Pain, terrific but remittent, followed the course of the great sciatic nerve of the right leg. It sometimes extended to the ankle and even to the dorsum of the foot and great toe. Tenderness on pressure, hyperæsthesia in some parts and anæsthesia in others were among the symptoms.

One form of puerperal paralysis is probably the

[1] Diseases of the Joints.

[2] Lecture on Sciatica, in a Series of American Lectures, edited by E. C. Seguin, M.D.

result of pressure upon the sacral plexus, or upon the lumbo-sacral cord where it passes over the brim of the pelvis; more probably the former, as the lumbo-sacral cord is particularly well protected in its descent. Few such cases, however, have been recorded. Imbert-Gourbèyre,[1] in his monograph on *Puerperal Paralyses*, speaks of several cases in which, from prolonged labor, and probably also from imprudent obstetrical manipulations, paralysis resulted. One of these cases, cited from Rademacher, was an incomplete and painful paraplegia coming on at the end of a long and difficult labor, and cured in eight days chiefly by friction. Another patient, thirty-six years old, during her third labor was paralyzed in both extremities, and recovered in a few months. Salvat is cited as reporting the case of a woman treated by him for vesico-vaginal fissure, with paraplegia, produced by the long stay of the head of the fœtus in the inferior strait. Another patient, thirty-two years old, during her fourth labor, which was prolonged and the delivery by forceps, suffered great pain in the loins, accompanied by feebleness and swelling of the legs. The feebleness increased to paraplegia, and she had lancinating pain, paræsthesia, and cramps in the limbs. These cases are imperfectly reported, and, as the neural symptoms were bilateral, it is possible that some of them may have been spinal. It is, however, more likely that they were due to direct traumatism of the lumbo-sacral plexuses. Dr. Dercum, of Philadelphia, has reported to me, verbally, some particulars about a case of unilateral paralysis, atrophy, and anæsthesia of the leg following delivery, and apparently due to pressure on the sacral plexus in the floor of the pelvis.

Dr. Howard A. Kelly, Associate Professor of Obstetrics in the University of Pennsylvania, has kindly furnished me with brief notes of two interesting cases supposed for a long time to have been purely gynecological. The first case, Mrs. X., had passed through a difficult instrumental confinement some twelve years before coming under observation. She visited many prominent gynecologists, and underwent a number of operations, the last being the removal of two large tubes and the ovaries. She was relieved of menstrual exacerbations, but still suffered great pain in the pelvis, for which she was receiving galvanism, message, and anti-lithic remedies. Her suffering continued unabated; and Prof. H. C. Wood, in whose charge she was, called Dr. Kelly in consultation. A careful examination showed that the uterus and its surroundings were perfectly free from disease. On making a careful rectal examination, however, outlining the sacro-sciatic ligament and pyriform muscle, and carefully palpating the roots of the great sciatic nerve, upon touching one cord she gave a sudden scream, at the same time doubling up her leg and jerking her body in bed. Here, directly over the roots of the left sciatic nerve—the left sacral plexus—was the only diseased area which could be detected in the pelvis. All subsequent treatment was directed to this condition.

In a second case the patient had constant pelvic pain, which she described more as a soreness, and located "back of her womb." She had been for several years since the birth of her last child under the care of gynecologists, who had not been able to give her any relief whatever. It was found by exploration that the only point of tenderness in the pelvis was at the roots of the sciatic nerve, and here she at once located all her pain, when the doctor introduced his finger into the rectum and made pressure on the nerve trunks. The case was one of neuritis. As Dr. Kelly remarks in the communication sending the notes of these cases, they teach the value of exploring the pelvis outside of the uterus and its annexes.

In one interesting case of railroad injury, supposed to be an example of railroad brain and spine, careful examination showed exquisite tenderness over both sacral plexuses, but particularly marked on one side. The plexuses were palpated through the rectum. This patient suffered great pain and tenderness in the lumbar and sacral and sacro-ischiatic regions and also complained of general weakness and pains in the lower extremities. She was pregnant at the time the accident occurred, and suffered greatly later at the time of her labor, the child dying during parturition. She had other cerebral and general nervous symptoms.

In rare cases of extensive disease of the rectum or of immense fecal accumulations, the sacral plexus or some of the intra-pelvic nerves may be compressed or irritated, or both, and thus give rise to great suffering. Pelvic cellulitis may occur even in the male, and also give symptoms of irritation and of compression of the sacral plexus. Skjeldrup[1] describes such a case in a man fifty years old, in which examination per rectum showed a hard tumor. Muir, quoted by Skjeldrup, has published a similar case. Mitchell[2] speaks of a case in which the patient suffered from numbness in the left foot and leg, followed by increasing loss of power to flex the foot. The peroneal muscles were found to have lost electrical response. On vaginal examination she was discovered to have a large growth behind and to the left of the womb. Innumerable cases of pelvic cellulitis in the female are of course on record, but in few have the sensory, motor, and other neural

[1] Mém. de l'Academie roy., vol. xxv.

[1] Tidsskrift f. Prakt. Med., quoted in Medical Register, vol. iv., September 15, 1888.

[2] Injuries of Nerves.

symptoms been reported with sufficient care to allow of anything but a general diagnosis. If gynecologists paid strict attention to the exact distribution of the pain in their cases of pelvic inflammation, abscess and growths, they would have a surer hold on early diagnosis. The character of the pain in these cases usually receives fuller attention than its distribution as would be naturally expected.

It is well known that neuromata occur somewhat frequently in connection with the cords or branches of the brachial plexus. Doubtless these growths now and then are present also in both the sacral and lumbar plexuses, and are overlooked. I have not been able to find reports of such cases, but it is probable that occasional rare forms of intractable sciatica, or other forms of neuralgia of the lower extremity in the distribution of some of the sacral nerves, are due to growths of this character.

Putnam[1] has reported an instructive case of sarcoma involving the intra-pelvic nerves, notes of the autopsy being given. The first and a recurring symptom was pain in the middle toe of the left foot. In six months the sacral region became extremely painful, and also the posterior and outer surface of the thigh, and the outer side of the leg and foot. The pain was accompanied by some paræsthesia, especially in the outer half of the left foot.

The right leg was attacked with severe pain, confined to the posterior and outer side of the thigh, nearly six months after the left. The pain abated, and renewed itself in the left leg. Walking became difficult. The muscular weakness affected not only the muscles of the sciatic distribution, but also the quadriceps extensor, and the psoas and iliacus. Slight tactile insensibility was present in the vicinity of the anus. Applications of galvanism were very painful. Knee-jerk was absent on both sides. No tumor could be discovered by rectal examination.

I have seen several cases of intra-pelvic or pelvic growths, causing pressure upon the sacral plexus or involving some of its cords or branches. In one an autopsy confirmed the diagnosis.[2] A man who had been treated for many months for sciatica, had pain chiefly down the back of the thigh, in, but not strictly confined to, the line of the sciatic nerve. The pain was altogether in the right leg; it was increased by pressure and movement, and he could not bring the foot firmly on the floor. A marked symptom was swelling of the leg, the left thigh measuring thirteen and a quarter inches; middle of leg fifteen inches; ankle eight inches; the right thigh twenty-one and a half inches; middle of leg fourteen inches; ankle nine and a half inches. The thigh presented a solid œdematous condition, with distinct pitting on pressure. A tendency to outward rotation was present. Pressure at the sciatic notch seemed to produce more pain than pressure elsewhere in the leg. Some of the abdominal muscles of the right side were cramped and tense, although those of the left side were relaxed. Movement of the limb caused pain. Examination by the rectum showed distinctly a solid resisting growth on the right side. In another case the diagnosis of sciatica had been made and persisted in for many months, but examination by the rectum revealed a tumor. The nerves of nearly the entire sacral distribution were involved, but very irregularly, in pain, anæsthesia, paralysis, and atrophy. In still another case, at the Philadelphia Hospital, the patient was also treated for a long time for sciatica, but close examination demonstrated disease of the acetabulum, and after death a large osteo-sarcomatous growth was found. Miles,[1] of Baltimore, has contributed a case of malignant disease of the pelvis which was supposed to be one of sciatica. The patient developed a malignant tumor about the hip, of which he died. Examination both externally and by the rectum revealed nothing. The one great symptom was pain in the sciatic distribution. One important practical point is that all of these cases had been treated for other affections, chiefly for sciatica or spinal disease.

A few interesting gunshot wounds of the sacral plexus have been reported, and many other cases equally interesting of rectal and pelvic gunshot injuries in which the nerve cords escaped. Habgood[2] has recently reported a bullet wound of the pelvis involving the rectum, in which, under antiseptic treatment, the patient rapidly recovered. This patient suffered great pain, not closely described as to its particular distribution. The bullet passed inward through the great sacro-sciatic notch. During the American war 103 cases of gunshot wounds are reported, of which 44, or 42.7 per cent., proved fatal. One case of gunshot wound of the sacral plexus is reported in vol. ii., *Medical and Surgical History of the War of the Rebellion*, p. 341. The patient, a private, aged twenty-three years, was wounded at Gettysburg. He was treated on the field until August 21st, and then admitted to Camp Letterman Hospital. Acting Assistant Surgeon H. H. Sutton reported that a ball from a Sharp's carbine entered the left side of the sacrum at the third segment, passed into the pelvis and there lodged. The ball in its passage injured the sacral plexus, consequently

[1] Journ. Nerv. and Ment. Dis., vol. xiv., Sept. and Oct. 1887, p. 601.

[2] Three of these cases were briefly referred to at the meeting of the American Neurological Association, 1887.

[1] Journ. Nerv. and Ment. Dis., vol. xiv., Sept. and Oct. 1887, p. 666.

[2] Manitoba, Northwest and British Columbia Lancet, 1887–8. Also Brit. Med. Journ.

the leg of the corresponding side became paralyzed, but the natural feeling and movements of the limb were gradually returning when the patient was admitted. Unfortunately, a study of this case as to sensation and motion was not made or not recorded.

On general principles I can see no reason why neuritis of the sacral plexus, either spontaneous, rheumatic, infectious, or of unknown cause, may not occur with moderate frequency. Neuritis of the brachial plexus, either in its entirety or in some of its subdivisions, is a well-known and often investigated disease; but the sacral and lumbar plexuses seem to have rarely attracted the attention of physicians with the idea that they were the subjects of neuritis. The surroundings of the sacral plexus are such as to render it more liable than the brachial to inflammation, either by contiguity or by causes acting through its environment. It is, perhaps, less liable to rheumatic inflammation. In every obscure case of unilateral, or even bilateral, pain in the extremities, whether associated with anæsthesia and paræsthesia or not, the sacral plexuses should be carefully examined by palpation through the rectum. A word of caution is perhaps here necessary. In some individuals, particularly females, of a highly nervous temperament, it is possible that pressure upon the comparatively exposed intra-pelvic nerves, reached by the finger in the rectum, may give rise to pain, which by psychical influence will be exaggerated so as to mislead the physician into supposing that the nerves are in a state of inflammation when such is not the case.

The following cases described by Dr. L. C. Gray[1] are cases in point where a rectal examination might have been of service for diagnosis.

The first patient felt tingling pains through both buttocks, the perineum, the scrotum, the tip of the penis, and down the back of both thighs, with some smarting in urination. As the result of the Turkish and Russian baths these symptoms were violently augmented and high fever ensued. Sexual desire was entirely lost, as were also the skin and cremaster reflexes. The patient was sent to the country and had a violent attack of supra-orbital neuralgia, after which he recovered.

The other case was a woman, thirty-five years old, who was suddenly attacked with sharp pain in the buttocks, perineum, labia, and down the back of the thighs to the knees, with simultaneous retention of urine. Vesical anæsthesia came on later, but no motor impairment. Over the area of pain was also impairment of the senses of touch, temperature, and pain, but slightly less near the knee than above.

These cases are sufficient to show the importance of the subject and the frequent actual occurrence of the forms of lesions involving the sacral plexus or other intra-pelvic nerves.

Let us briefly consider the main points in the diagnosis of such cases. In the first place, the great value of close examination by the rectum, which has already been dwelt upon, cannot be over-rated. Another important general point is as to the unilateral or bilateral character of these affections. They are commonly unilateral, or begin on one side, and, in exceptional cases, become bilateral. In some cases, however, of spontaneous neuritis, or pressure neuritis, or palsy, as in those reported by Imbert Gourbèyre, the symptoms may be nearly uniformly bilateral.

Large compressing and destructive lesions of the sacral plexus give nearly the same syndrome, only usually unilateral, as is presented by lesions of the lower part of the cauda equina. These symptoms, of course, vary somewhat according to the amount of nerve involvement. They are pain variously distributed in the domain of the sacral nerves—in the buttock, backs of the thighs and legs, soles of the feet and outer sides of the feet; anæsthesia, analgesia, and paræsthesia in the distribution of the nerves, from the second sacral nerve down to and including the coccygeal; paralysis and wasting particularly in the muscles below the knee, nearly all of which are in the sacral distribution; and in those muscles above the knee which occupy the distribution of the great sciatic and gluteal, small sciatic and superior gluteal nerves; trophic disorders, such as bedsores, perforating ulcers, abscesses, joint and bone changes, etc.; and vasomotor affections, such as changes in surface temperature, flushing, pallor, sweating, œdema, priapism, and coldness of the extremities. The bladder and rectum will be involved when the lowest sacral nerves are implicated—the nerves which do not strictly belong to the plexus. Reactions of degenerations will be present in most of the paralyzed muscles. Knee-jerk, ankle clonus, and the plantar reflex are likely to be absent on both sides; the cremasteric reflex as likely to be retained. The symptoms enumerated for lesions of the cauda equina are, in nineteen cases out of twenty, bilateral, although often not absolutely symmetrical. Consider now the same symptom-picture in one limb, and we have the phenomena produced by a large irritating, compressing, and destroying lesion of the sacral plexus.

Thorburn's[1] commentary on one of his cases of cauda equina lesion might, if the symptoms were not bilateral, be almost equally applicable to a pelvic plexus lesion. He says of this case that there was sensory paralysis of all the nerves of the sacral plexus, and possibly of the obturator, but not of the anterior crural or other lumbar nerves; the peri-

[1] Journ. Nerv. and Ment. Dis., vol. xiii., 1886, p. 743.

[1] Brain, January, 1888.

neum, penis, scrotum, and urethra, being supplied by branches of the pudic, were anæsthetic, but the root of the scrotum retained sensation, owing to the presence of twigs of the ilio-inguinal nerves, which, however, only descend to a very short distance. Paralysis with the reaction of degeneration was complete in the muscles supplied by the nerves of the sacral plexus. Those supplied by the anterior crural, although presenting the reaction of degeneration, were only weakened, and the adductors, supplied by the obturator, appeared also to retain some power. Cremasteric reflex remained, but below this point reflex action was lost.

Unilateral lesions of the sacral network must be occasionally differentiated from unilateral affections of the cauda equina. Usually, of course, cauda equinal symptoms are bilateral; but if the lesions are hemorrhagic, inflammatory, or from injury, they often are not symmetrically bilateral, and rarely they may be unilateral as in a case described by Erichsen, and quoted by Thorburn. It is, indeed, doubtful whether this case, which recovered under four months' treatment, was not, after all, one of rheumatic or traumatic neuritis of the sacral plexus. The patient could not stand but could move his legs in bed; he had not complete paralysis except in the peronei and extensors of the left ankle; rapid wasting of the left leg came on; numbness and tingling were present on the outer side of the left thigh, and partial loss of sensation below the left knee. The right limb was normal, he had occasional loss of control over the sphincters, and coldness of the extremities, especially of the left foot. The case was due to injury and came on gradually during ten days. Tenderness over the third lumbar vertebra was present after the tenth day, and symptoms of cervical injury were also present.

Weir Mitchell has given some diagnostic rules for the separation of spinal and cerebral from nerve lesions. Evidently, however, these are applicable only to the separation of true spinal cord lesions from lesions of the spinal nerves whether within or outside of the spinal canal. In other words, he has not made any distinction between lesions of the cauda equina within the canal and those of the plexuses in the abdominal and pelvic cavities. With our present lights we have little difficulty in differentiating lesions which involve the spinal cord itself from peripheral lesions. A much greater difficulty, as just indicated, is that which arises in separating irregular lesions of the extreme lower part of the cauda equina from lesions, particularly bilateral lesions, of the plexuses outside of the spine.

In cases of extensive bilateral lesions of the abdominal or pelvic plexuses, supposed to be cases of traumatic myelitis, the points mentioned by Mitchell might be of some service. He speaks, for instance, of a plan proposed by Stich.

"When cutaneous anæsthesia exists," he says "it is often easy to learn whether its cause lies in the nerves or in the central organs by following this plan. If the insensible region can be made the point of departure of reflex movements, the anæsthesia is of central birth, because to have reflex motion an excitation must have reached the spine, by which we infer healthy nerves, while the mere presence of anæsthesia will in this case indicate the existence of disease in the spine above the point which is the seat of the reflex power exhibited. If the proof be negative, and if the excitation cause no movement, we can arrive at no definite conclusion until, following the same sensitive nerve up the limb, and by seeking to excite it through its reflex acts, by touching the skin with a hot sponge or ice at successive points, we learn if at any upper portion of the tegument we can produce this result. Should we get an affirmative reply, we may presume that the anæsthesia is of peripheral origin. When, finally, the answer is negative up to the spine itself we learn nothing by this method, the total absence of all reflex movement being equally compatible with either loss of conducting power in the peripheral trunks and branches or with extensive alteration of spinal centres. The value of this means must be necessarily limited by the difficulty of exciting reflex acts from all regions of the skin." (*Injuries of Nerves.*)

Of another point which has, I think, but limited application, or is of doubtful value, Mitchell writes as follows:

"There is another peculiarity which separates all extra-central nerve lesions from cerebral, and also from spinal disease; but I do not feel that as yet it is available to any large extent. I noticed some years ago that in even the gravest lesions of nerve trunks, if a touch were felt at all, it was felt with no remarkable delay; while in many central palsies, if severe, and especially in such as result from extensive spinal malady, the time required for transmission to the sensorium was, as Cruveilhier pointed out, very largely increased—so much so, indeed, as to be readily estimated in a rough way by the hand of a watch beating quarter seconds, or still better by a metronome. The cause of this difference is still obscure to me, nor is it easy to see why diffuse sclerosis, for example, should so retard a sensory impression, while injured nerve fibres have no such effect."

Certain intra-pelvic neuralgias must be distinguished from neuritis or other lesions of the sacral plexus and intra-pelvic nerves. It is a question whether some of the cases reported as examples of neuralgia have not been rather forms of neuritis. Mitchell,[1] under the name of "Anal and Perineal Neuralgia," reported several interesting cases of this kind. This disorder, as described by him, is a painful affection of the anal and perineal regions, accompanied or not, as the case may be, with spasmodic contraction of the anal muscles and of those of the perineum. It is met with in locomotor ataxia, and also as an isolated affection usually following masturbation or sexual intercourse. It is likely that in these cases examination by the rectum would show tenderness over the anal and perineal nerves. Treatment by rest and anodyne suppositories is most useful, and points also to the probable neuritic character of the affection.

LESIONS OF THE LUMBAR PLEXUS.

One of the commonest and most misleading affections involving the lumbar plexus is that compound lesion to which I have already referred, usually described under the comprehensive term psoas abscess. Eleven years ago I called attention to the frequent simulation by it of certain special forms of nervous affection, painful, paralytic, and spasmodic;[1] and, of course, the subject has been frequently written about, both before and since. Still, mistakes are constantly being made, and the subject is of considerable importance to neurologists. In one of my cases the diagnosis of crural neuralgia had been made, and no abscess was suspected. Pain most severe distally extended from Poupart's ligament to the inner side of the knee, along the course of the anterior crural nerve and its internal saphenous branch. This pain was relieved by sitting, or lying, or flexing the thigh on the pelvis, at the same time keeping the knee bent. A partial paralysis, or pseudo-paralysis, of the ilio-psoas muscles was present, the patient being compelled to lift the leg with his hands in order to cross the knee.

In another case on which I made an autopsy, the patient died three years after his initial symptoms, having been, in the meantime, the victim of numerous and diverse diagnoses, such as lumbago, sciatica, rheumatism, and paralysis from spinal exhaustion. His first symptom was severe pain in the lumbar region, which later extended down the right hip, and still later down the inner aspect of the thigh. He became unable to walk without support in eighteen months. It is not necessary to describe his progressive symptoms in detail. Later, he carried his body flexed upon the thigh, and both legs were wasted, the right more than the left. A significant fact was the absence of implication of the bladder and rectum, showing that the ano-vesical nerves, which arise from the conus and are distributed to the sacral rather than to the lumbar plexus, escaped. An accurate localizing study of this case, in its initial period, would probably have indicated its true nature; and operation performed early, after the method recommended by Treves and others, might have saved the life of the patient.

In one historical surgical case,[2] that of President Garfield, a quick appreciation of the symptoms produced by irritative lesions of separate cords of the lumbar plexus, and of the lumbo-sacral roots, was of considerable service in reaching a conclusion as to the exact course taken by the bullet. This case is also probably a study in intra-spinal nerve-root localization and worthy in this connection of our passing attention. Studying its abundant literature I find somewhat differing statements as to the nervous symptoms presented. The question whether the subjective symptoms presented sufficient facts for diagnosis was argued pro and con. with much warmth in some of the medical journals. One report states that the President suffered pains of a symmetrical character in both feet; another that hyperæsthesia was always more severe in the right than in the left foot and extended up the leg to some distance, and it was far more intense upon the dorsal than upon the plantar surface. The different contributors to the controversy all, however, agreed that hyperæsthesia was present on the right side of the scrotum, differing only as to whether it also extended over the lower abdominal region. The pointing was clearly to injury of the right ilio-inguinal, and probably also of the right ilio-hypogastric nerve, or their common trunk, as these nerves are both derived from the first lumbar root, and as a frequent position for this root is almost exactly where the ball entered the lumbar vertebra.

The ground has been taken that the cause of the symmetrical, or at least bilateral, pains in the feet was central, and therefore due to a lesion by jarring or concussion of the spinal centres opposite or near the vertebra perforated by the bullet. The terrific jarring of the spinal column by the concussion of the bullet was amply sufficient to have caused minute extravasations at the origins of the last lumbar and upper sacral nerves, which may have so irritated the roots of these nerves as to have caused bilateral pains in the distal portions of the lower extremities. The sensory nerves for the feet on both the posterior and anterior surfaces are derived from the sacral plexus; with the exception of the long or internal saphenous nerve, a branch of the anterior crural derived from the third and fourth lumbar roots. Within the spinal canal the nerves which go to form both the lumbar and sacral plexuses arise in a vertical extent of the cord which is very short, and is mainly opposite to the last dorsal and first lumbar vertebræ. It is significant that the roots of the first, second, and third sacral nerves are almost exactly opposite the upper part of the first lumbar vertebra where it was perforated by the bullet. The phenomena presented seem to admit of no other reasonable explanation. A crushing or destructive lesion of the lumbo-sacral region of the spinal cord was out of the question, as such a condition of paralysis, atrophy, anæsthesia, vaso-motor and trophic disturbances, and interference with the functions of the bladder and rectum, would have been present as could not have deceived.

True lumbo-abdominal neuralgia is comparatively rare, and, therefore, in cases of lumbo-abdominal pain, whether joined with crural pain or not, we

[1] Trans. Med. Soc. Pennsylvania, 1878.

[2] Among the contributions discussing this case are the following: Official Report—Amer. Journ. Med. Sci., Oct. 1888; White—MED. NEWS, vol. xl., No. 25, June 24, 1882; Bliss—Med. Rec., Oct. 8, 1881; Walsh—Walsh's Retrospect, Oct. 1888; Baker—MED. NEWS, vol. xli., No. 5, July 29, 1882.

should carefully inquire for local lesions of the lumbar plexus, as aneurisms, abscesses, neuritis, etc. A close study of such a case will often reveal its true nature. Lumbo-abdominal neuralgia, as stated by Erb, is commonly associated with intercostal. The presence of marked motor and anæsthetic disturbances with certain vesical, rectal, and sexual symptoms will help to decide against true neuralgia and in favor of lumbar plexus-disease, if the affection is unilateral. Many of the cases of so-called lumbar, sacral, abdominal, lumbo-abdominal, and other forms of plexic neuralgias are in reality cases of neuritis of these plexuses.

Certain affections which involve some of the cords or branches of the lumbar plexus, particularly abscesses—lumbar, iliac, psoas, and perinephritic—have not infrequently been wrongly supposed to be other diseases. Lydston[1] has reported a case in which acute lumbar abscess simulated at its beginning nephritic colic. A young man, aged nineteen, who had been previously healthy, awoke suddenly one morning with a severe pain in his right iliolumbar region, doubtless due to implication of the upper lumbar nerves. This pain had persisted for the entire time prior to his visit, and had been but imperfectly relieved by morphia. In view of the history and physical condition of this case, a diagnosis of renal calculus—probably impacted in the ureter—was made, as, according to the patient's statements, the location of the pain had gradually descended toward the right iliac fossa. The usual line of treatment for the condition which was supposed to exist was ordered, but later a large abscess pointed in the back to the right of the spine, between the ribs and the crest of the ilium.

An available knowledge of the segmental distribution of sensory nerves in the trunk and extremities may be of considerable service in diagnosticating lesions of the sacral and lumbar plexuses, even at an early period. Pain, anæsthesia, and paræsthesia are often experienced in these cases in special peripheral areas, as illustrated in the case of President Garfield, and in the pelvic tumor reported by Dr. Putnam, to which reference has been made. In Putnam's case the first and a recurring symptom was pain in the middle toe of the left foot, and subsequently, other symptoms were paræsthesia of the dorsum of the foot, and later of the outer side of the leg and the posterior aspect of the leg and thigh. These symptoms definitely indicated involvement of sacral nerve cords. The only portion of the foot which escaped was the inner side and great toe supplied by the long saphenous nerve, a branch of the lumbar plexus. The sensory symptoms and the particular order of their occurrence fairly indicated the particular method of the progressive involvement of the nerve cords and branches of the sacral plexus. Pain in cases of lesion of the nerve roots, either in their intra-spinal course or in the plexuses, is often projected to distal portions of the sensory nerves, and a close study of the distribution and progress of this pain will lead to a diagnosis of the location of the lesion producing it.

The question of operation for certain lesions of both the sacral and lumbar plexuses is one of some practical interest. It is probable that trephining the pelvis could be performed successfully in a few cases for lesions of the sacral plexus, such as abscess and removal of intra-pelvic growths, or excision of parts or the whole of the plexus. This could, probably, be best done by entering the pelvis from the median line above and behind; but I leave the question of the best place and method of operation for the consideration of surgical anatomists, simply suggesting its performance for some of the lesions discussed in this paper. In gynecological surgery several intra-pelvic operations by the sacro-coccygeal route have recently been reported; and this plan of operation has received the indorsement of distinguished German surgeons. It has been employed for pelvic abscess, for disease of the ovaries and Fallopian tubes, and for extirpation of the uterus. The lumbar plexus, in part of its course, can be reached by operation through the back.

MEDICAL PROGRESS.

Laparotomy in Visceral Wounds.—In an article on laparotomy in visceral gunshot and stab wounds (*Nashville Journal of Medicine and Surgery*, May, 1889), DR. C. S. BRIGGS presents the following general conclusions:

1. That laparotomy for traumatism should be resorted to in the majority of cases in which the existence of visceral injury is clearly established, the exceptions being such instances as from the great extent or necessarily fatal character of the wound, the possibility of recovery is absolutely precluded.

2. That where doubt exists as to the presence of gastro-intestinal lesions, Senn's insufflation method should be employed.

3. That the median incision is best adapted for laparotomy in these cases, except in penetrating wounds received from behind or where it is evident that one of the immovable viscera has been injured at such a point as to render the necessary examination impossible through the opening provided by the median incision.

4. That inspection of the abdominal contents should be thorough and painstaking, even at the risk of added shock by prolonged search, though expedition in this, as well as in other parts of the procedure, is certainly to be recommended.

5. That while it is unquestionably necessary for speedy repair in the approximation of visceral wounds to unite serosa to serosa, multiplied stitching is to be avoided, inasmuch as the nature of the reparative process in this class of wounds does not require such intimate closure,

the advantage to be obtained thereby is more than counterbalanced by the loss of time, and a great number of stitches in itself constitutes an element of danger.

6. That the continuous suture is the best adapted for nearly all intestinal wounds, as it is the simplest, the most quickly made, and can be used in such a manner as to possess all the advantages of the Lembert suture.

7. That when wounds with great loss of substance or closely placed multiple wounds are met with, Senn's approximation method by intestinal anastomosis may, when better understood, be substituted for resection, now considered necessary in such complications.

8. That the peritoneal toilet should be carefully made, and that the penetrating wound of the abdominal wall should be closed with as scrupulous regard for the care of the peritoneal injury at that point as at the wound in the median line.

Bicarbonate of Sodium and Bichloride of Mercury in the Treatment of Yellow Fever.—DR. GEORGE M. STERNBERG, in the *Therapeutic Gazette* of May 15, 1889, gives the results of his treatment of yellow fever with bicarbonate of soda and bichloride of mercury. Last August Dr. Sternberg published in the same journal a preliminary note on this treatment, and in the present number confirms its efficacy by numerous statistics. The original formula is as follows:

℞.—Bicarbonate of soda . . 150 grains.
Bichloride of mercury . . $\frac{3}{10}$ grain.
Water . . . . . 1 quart.—M.

Dose, about 1½ ounces every hour, to be given *ice-cold*.

The results of this treatment in Decatur, Ala., showed that out of thirty-two cases occurring among whites only four died; and out of thirty-two cases among colored people there were no deaths. The cases were reported by four practitioners. This method in Jacksonville was even attended with greater success. Out of one hundred and six cases treated with the alkaline and bichloride method, there occurred but five deaths—a mortality of 4.7 per cent. Seventy-nine of these cases and all the deaths were among whites—a mortality of 6.3 per cent. Twenty-seven cases were colored, with no deaths.

In twelve consecutive cases treated in the Garcini Hospital, in Havana, there were no deaths. Patients in which this treatment was used were never observed to have suppression of urine. Another list of eighty-nine cases comes from a Jacksonville practitioner, who exclusively used this treatment, with a record of five deaths. In Rio de Janeiro, out of four cases treated, three recovered and one died.

From his most recent experiences, Dr. Sternberg has found it advisable to make the following modification of his formula:

℞.—Bicarbonate of soda . . . ʒjv.
Corrosive chloride of mercury . gr. ½.
Pure water . . . . . 1 quart.—M.

Dose, about 1½ ounces every hour, to be given *ice-cold*.

The amount given should, however, vary with the age of the patient.

The Value of Glycerine Suppositories.—During the last meeting of the Greifswald Medical Society, reported in the *Deutsche med. Wochenschr.*, May 16, 1889, DR. NIESEL read a paper concerning his experiences with glycerine suppositories. He has used them 100 times in forty different cases, and does not think they are as valuable as has hitherto been considered. In cases of mild constipation, resulting merely from a large accumulation of feces in the lower bowel, the use of glycerine suppositories was quickly followed by a copious evacuation of feces, but in chronic constipation, or in cases where the bowels were in an atonic condition the suppositories had little or no effect. Unpleasant accompanying symptoms were never observed.

Picric Acid in Skin Diseases.—DR. CALVELLI, in the *Gazzeta Medica Lombarda*, March 2, 1889, gives the following formula for picric acid, which he says has proved of the greatest value in erysipelas:

℞.—Picric acid . . . . . grs. 24.
Water . . . . . f ʒ viij.

This application he combines with hypodermatic injections of quinine. The action of the drug was most favorable even in severe cases. It is also of value in cases of lymphangitis, eczema rubrum, and erythema. In a word, it may be regarded as a good local antiphlogistic.—*Revue Général de Clinique et de Thérapeutique*, March 28, 1889.

Trephining of the Pelvis for Suppurative Psoitis.—In the *Revue de Chirurgie* for March, DR. MICHEL GANGOLPHE, of Lyons, has a noteworthy article on this subject. He gives the histories of two cases of his own and a case of Boucher's, and refers to articles by Weiss, Fischer, Rinne, and Condamin. His conclusions are that infectious and even traumatic psoitis is of exceptional gravity, whether on account of the patient's general condition or of the extent of the local trouble, especially the possibility of implication of the hip-joint; that early evacuation of the pent-up pus is the best means of preventing a fatal issue; that trephining of the pelvis, as practised by him, is easily and rapidly done, is free from danger, and admits of the establishment of perfect drainage of the iliac cavity; and that, according to the features of the particular case, it may be associated with one of the classical lumbar, inguino-crural, or posterior crural incisions. The situation that he considers most eligible is a point nearly three fingerbreadths below the crest of the ilium, and three fingerbreadths behind the anterior superior spine.—*New York Medical Journal*, May 18, 1889.

Persistent Vomiting.—Persistent vomiting, especially that of pregnancy, is often most difficult to overcome, and baffles every effort of the physician; indeed, several fatal cases have been lately reported. DR. BLUMENSANDT, in *L' Union Médical* of May 2, 1889, says that he has found the following formula invaluable in such cases:

℞.—Hydrochlorate of cocaine . . 3 grains.
Tincture of anise . . . f ʒijss.
Spirits of menthol . . . f ʒijss.
Linden-flower water . . . f ʒv.
Syrup of cinnamon . . . f ʒj.—M.

A dessertspoonful to be given every hour until the vomiting has ceased.

The Prophylaxis of Diphtheria.—DR. L. BARD concludes an exhaustive article on this subject, which was con-

tinued through six numbers of the *Lyon Médical*, ending March 24, 1889, with the following summary:

The most reasonable and adaptable measures to insure the prophylaxis of diphtheria are as follows:

1. Prolonged isolation of the patients in special wards or buildings.

2. Total isolation of the sick, and also isolation—as far as possible—of those in attendance upon them.

3. Watchful care over those who might possibly be sickening with the disease, *i. e.*, the brothers or sisters of the patient, and others who have been thrown in contact with him.

4. Special inspection of schools, in order, as far as possible, to insure the removal of all convalescents and those with suspicious symptoms.

5. The immediate disinfection of the patient and all articles soiled by him.

6. The observation of rigid cleanliness and strict antiseptic precautions by all attendants of the patient, in order to prevent the spread of the germs through them.

7. Thorough disinfection of all utensils used by the patient, as well as of the room, etc.

The Treatment of Granular Conjunctivitis by Corrosive Sublimate.—ARNAUTS (*Annales d'Oculistique*, Jan.–Feb. 1889) gives some records of the results obtained in the treatment of trachoma, by corrosive sublimate, at the clinic of Dr. Romiée, during three years. His experience is strongly in favor of this remedy, in preference to the more commonly used nitrate of silver, sulphate of copper, and other caustics and astringents. He is especially pleased with its effect in old chronic cases, with severe pannus; and states that the disappearance of the corneal vascularity is so rapid that it suggests some special action of the sublimate on the newly formed vessels.

The following is the method employed. The patients are seen, if possible, twice a week, and at each visit, after instillation of a few drops of a five per cent. solution of cocaine, the conjunctival surface of the lids is brushed with a solution of corrosive sublimate, 1 to 120 or 1 to 100. In addition, collyria of the same salt are given, of the strength of 1 to 500 or 1 to 400, which the patients are directed to drop into the conjunctival sac three times daily. These drops give rise to some irritation and conjunctival injection, which are said to pass off in a few minutes. In sensitive patients, a weak solution of cocaine may be previously applied.

In the *Recueil d'Ophtalmologie* for February, 1888, STADERINI, writing on this subject, gave a very favorable account of his experience of the use of corrosive sublimate, stating that the results obtained by its employment in all stages of granular conjunctivitis were very satisfactory. He suggested that its action was that of an antiseptic, and a solvent of the lymphoid infiltration in the submucous tissue. If the microbe described by Sattler, Poncet, and others, be the chief or sole cause of trachomatous conjunctivitis, corrosive sublimate should prove of great efficacy in the treatment.—*Ophthalmic Review*, May, 1889.

Treatment of Whooping-cough with Carbolic Acid Spray.—DR. MAURIAC, of Bordeaux, who for some time has been strongly advocating the use of resorcin in cases of whooping-cough, has recently published the results of a series of experiments regarding the value of carbolic acid spray in this disease. His results are undoubtedly good. The spray is applied by means of a large steam atomizer, and about a quart of a five per cent. solution of carbolic acid is daily sprayed into the throat. The patient should be confined to one room until recovery is complete. In most cases the paroxysms of coughing were speedily relieved and the disease disappeared within twenty days.—*Münchener med. Wochenschrift*, April 23, 1889.

Belladonna in Whooping-cough.—Belladonna may be given both during the catarrhal as well as the spasmodic period of whooping-cough, and its use is usually attended with success. DR. J. SIMON, *Gazette hebd. Méd. et de Chir.*, May 3, 1889, advises its use during the catarrhal period, in the following formula:

℞.—Tincture of belladonna } āā gtt. x.
Tincture of aconite }
Cherry-laurel water . . f ℥ijss.
Linden-flower water . . f ℥iij.
Syrup of lactucarium . . f ℥j.—M.

A teaspoonful every three hours.

During the spasmodic period Drs. Hufeland and Trousseau, of Vienna, advise the use of powdered belladonna in preference to tincture:

℞.—Powdered belladonna root . 2 grains.
White sugar . . . ℥ijss.—M.

Divide into ten powders, and give one morning and night.

The above is for infants; for a larger child, the following may be substituted:

℞.—Belladonna root . . . 2 grains.
Bicarbonate of soda } āā 24 " —M.
Powdered white sugar }

Divide into ten powders, one to be given two or three times a day.

Dr. Monti considers the combination of belladonna with quinine of greater value than when given alone. He prescribes it as follows:

℞.—Powdered belladonna root . 2 grains.
Sulphate of quinine . . 8 "
White pulverized sugar . 31 " —M.

Divide into ten powders. Dose, two or three a day.

Creolin in Gynecology.—DR. JULES CHÉRON, in the *Gazette de Gynecologie*, May 1, 1889, contributes further valuable matter to the creolin question. He has used it extensively in female blenorrhagia with unquestionable success. He has also used it as a disinfectant in cases of purulent endometritis with excellent results. Its effects were non-irritant, but it produced a healthy appearance of the parts. It most admirably takes the place of iodoform.

Lanolin-sublimate an Antiseptic.—The majority of antiseptics seem to loose their strength almost entirely when mixed with oily or fatty substances; lanolin, however, appears to be a base which will not deprive these drugs of their antiseptic properties. DR. GOTTSTEIN (*Therap. Monatshefte*, No. 3, 1889) has recently experimented

largely with lanolin-sublimate, and has found that the antiseptic properties of sublimate of mercury are in no-wise diminished by being mixed with lanolin. The ointment is prepared by mixing a solution of sublimate with hydrous lanolin. The strength of the mixture is usually from 1 : 5000 to 1 : 1000.—*Münchner med. Wochenschr.*, April 2, 1889.

Antiseptic Treatment of Typhlitis.—DR. BOUCHARD, in the *Gaz. Hebdomadaire*, April 5, 1889, bases his treatment of typhlitis on the following principles: First, to relieve the pain; second, to insure complete intestinal rest, and to reduce, as far as possible, all intestinal fermentation; third, to insure perfect asepsis of the large intestine.

The treatment should, therefore, be sedative, dietetic, and antiseptic.

1. The pain may be relieved by the use of poultices, mercurial-belladonna ointments, and hypodermatic injections of morphine.

2. To prevent possible obstruction of the bowels, mild laxatives, such as magnesia, or a dessertspoonful of castor oil, should be given. The use of strong purgatives is to be strictly avoided. The diet should consist of milk with lime-water, or with the yolk of an egg; solid food, or easily fermenting food, should not be given.

3. Complete antisepsis of the lower bowel can be insured by the use of antiseptic irrigations. Bouchard uses the following twice daily:

℞.—Water	1000	parts.
Borate of soda Tincture of benzoin Camphorated alcohol	āā 5	"

This solution should be used at a temperature of 100° F., two pints of the solution being used at each irrigation.

Treatment of Hypertrophy of the Breast.—The following treatment is advised by DR. KISCH in the *Deutsch med. Zeitung*. The primary treatment should consist in the use of the following salve:

℞.—Deodorized iodoform . .	1 part.
Vaseline	15 parts.
Tincture of menthol . .	q. s.—M.

This ointment should be applied to the breast daily. In the later stages, the salve may be substituted by the following lotion:

℞.—Alum	1 part.
Acetate of lead . . .	5 parts.
Dist. water	100 " —M.

Compresses wet with this mixture should be applied, and may be kept moist by covering them with a piece of rubber cloth.—*Revue Général de Clin. et de Thér.*, May 2, 1889.

Gastro-enterostomy.—At a recent meeting of the Royal Medical and Chirurgical Society, MR. HERBERT W. PAGE described a case of gastro-enterostomy in a man aged forty-eight, who had suffered from malignant pyloric obstruction for several months, and who was operated on according to the method of Woelfler in St. Mary's Hospital in December, 1887. He was much relieved by the operation; he regained his appetite, and the vomiting, which had been incessant and exhausting before, almost entirely ceased. He lived for seventy-two days in comparative comfort, but did not gain in weight, a circumstance due, it was believed, to the fact discovered at the necropsy that the lower end of the ileum had been sutured to the stomach.

Reference was made to a recent case in which the same accident befell Lauenstein, and special remarks were directed to this untoward feature and to the necessity of taking such steps at the operation as should secure the right piece of jejunum or upper ileum being chosen. An appended table contained in all thirty-eight cases, two of which were subjected to both pylorectomy and gastro-enterostomy at the same time. Of the thirty-six cases of gastroenterostomy alone fifteen were fatal, directly or indirectly as the result of the operation. Collapse was the most frequent cause of death, and examination of the table showed that those patients only were fitted to bear the operation who had not been greatly exhausted either by vomiting or by extension of the cancerous disease. It was suggested that the use of Senn's decalcified bone-plates, by doing away with the necessity of putting in so many sutures, was likely to shorten the time spent over the operation, and that thereby the risk of death from shock might be materially lessened. There had been a steady decline in the rate of mortality. In the first eighteen cases there were ten deaths, while in the second eighteen there were only five. In the writer's opinion gastroenterostomy was worthy of more attention than it had hitherto had in this country. In properly selected cases it appeared to him to be an operation distinctly justifiable, and one to be recommended, for it was capable of bringing relief from the distressing symptoms incidental to pyloric obstruction, and was thereby, in all probability, the means of prolonging life.

MR. BARKER commented on the duration of the operation, and urged that the time occupied would always vary with the dexterity of the surgeon; it was impossible to use a Lembert's suture rapidly without practice. In Germany, no surgeon performed this operation on the human subject without repeated practice. The whole operation had been completed in a quarter of an hour on one occasion.

MR. PAGE, in reply, said that he did not claim that the operation had prolonged life. On the contrary, he regretted that, owing to the lower end of the ileum having been put into connection with the stomach, life was possibly shortened. This error had occurred in the practice of another surgeon. He could not help thinking that careful perseverance in the use of the bone approximation plates, as advocated by Senn, of Milwaukee, would prove of value in the future.—*The British Med. Journ.*, May 18, 1889.

Creolin in Dysentery.—DR. N. P. OSSOWSKY contributes to the *Wiener medicinische Presse*, May 5, 1889, the history of sixteen cases of dysentery which were successfully treated with creolin irrigations of the bowels. A one-half per cent. solution was used for the purpose, and about two quarts were injected three or four times daily. In three cases the disease disappeared after the third irrigation, in nine the bloody stools ceased after the third day of treatment; the most obstinate was cured in six days. All the cases were most severe at the outset. Dr. Kolokoloff, in the same journal reports twelve cases which were cured by the same treatment.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE . . . . . $5.00.

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

PHILADELPHIA.

SATURDAY, JUNE 15, 1889.

THE SANITARY SITUATION AT JOHNSTOWN.

THE appalling disaster which has devastated Johnstown and vicinity is without parallel in this country. The magnitude of the calamity has arrested the attention and elicited the sympathy of the civilized world. The outpouring of offerings in aid of the survivors is unprecedented. The humane impulse to render personal assistance to a community overwhelmed and paralyzed by the most sudden and direful of events has brought to the scene hosts of noble-hearted and strong-handed men who are bending every exertion to assuage the sufferings and provide for the present wants of thousands of unfortunate ones who have been so suddenly swept of the possession of kinsmen, friends, and homes. The temporary wants of the people are being supplied with commendable alacrity, and there will be no want of funds for all needful purposes for the immediate future.

There are, however, problems of the most serious import, which demand immediate consideration by the wisest and coolest of heads. They involve the sanitary administration of the locality in behalf of local interests and the interests of more or less remote communities whose health is threatened by causes arising at Johnstown, unless the most prompt and effective measures are adopted for arresting them.

The Conemaugh flows into the Alleghany River and contributes to the water-supply of a large population. The pollution of this stream by the decomposing remains of human bodies and the putrefying carcasses of animals is a constant menace to the health of thousands of people who depend on the river to which it is tributary for their water-supply.

The danger of pollution from the scouring of the shores of the stream and the washing into it of cesspool and other deleterious organic matters could not be averted. The cause has ceased, but the effects are yet to be developed. There remains, however, a constant and increasingly dangerous source of pollution in the vast collection of débris overlying and choking up the river, which contains perhaps thousands of human and other remains in an advanced state of putrefaction, and hurtful matter of various kinds, which it is an imperative sanitary duty to get rid of at once. With every means within the power of human ingenuity to contrive, supplemented by ample resources, it is not thought possible to remove the wreckage, piecemeal, for several weeks. In the meantime there is great danger of disease by polluting the water and by poisoning the atmosphere with fetid vapors.

Notwithstanding the profound reverence for the dead which we all alike share, and the respect we owe to the feelings of the afflicted, the health of the living is a paramount question which in the conflict of opinions must take precedence of all other considerations. There should be no further delay of proper action. Too much time has been wasted already in almost fruitless attempts to remove the wreckage. The public health demands the immediate removal of the offensive material. The means have already been suggested and should have been carried out before this. By the application of the torch, swift and thorough destruction of the vast mass of combustible material will be effected, and what remains can be quickly removed. The purifying and destructive effects of fire must be resorted to as the last and only means of surely solving a problem which has baffled all devices hitherto employed. Until this has been accomplished and the river water has had time to purify itself, it use for drinking purposes should be avoided. Where from the necessities of the case this is impossible the water should be boiled, as advised by the State Board of Health.

It is not idle phantasy that draws a picture of danger from the gorge at the stone bridge. Experience, especially that of campaigns, has taught the lesson by which we are endeavoring to profit. It is

a matter of record that when soldiers have been exposed to the products of decomposition of animals, the influence on health has been most injurious. Pringle has shown this to be a decided cause of insalubrity. Diarrhœa and dysentery are the principal diseases, but other diseases are likely to be increased in severity. It may be remembered that at the siege of Sebastopol, where in the French camp a large number of dead horses lay exposed and decomposing for a number of days, the effect, as described by Reynal, was most disastrous upon the health of the troops.

The burial of the dead is another matter for serious consideration. In the haste incident to the pressure of the first few days, and in the unavoidable absence of careful sanitary supervision, sufficient attention has not been given to the selection of the places of interment and to the manner of burial. So vast a number of bodies crowded within a limited space, and in a porous soil, many of them being placed in shallow graves, will, at this season of the year, lead to rapid decomposition and the pollution of the air and wells, if proper precautions are not taken to prevent it.

The situation at Johnstown is similar to that of a battle-field after a sanguinary conflict. In time of war it becomes a necessity to bury in trenches, and when disinfectants are at hand they are freely used. But it is generally at some subsequent period that a more thorough sanitary treatment of the bodies takes place. At Metz the graves were disinfected with lime, charcoal, and sulphate of iron. Subsequently, for fear of contamination of the water-courses, the bodies were treated with chloride of lime, charcoal, and carbolic acid. The Belgian experience at Sedan favored the use of chloride of lime, nitric acid, sulphate of iron, and chlorine gas. Carbolic acid did not answer the purpose as well. The work of burial should now be conducted with the free use of disinfectants, and when completed, the early and incomplete graves should be uncovered, where necessary, and the bodies subjected to thorough treatment under skilled superintendence. The use of rapidly growing trees and shrubs is a most efficacious means for the absorption from the soil of organic substances.

There are special sanitary reasons for the prompt removal of the deposits from the streets and spaces of Johnstown. The character of the deposit and its exposure to the heat of this season of the year make it highly probable that unhealthy effluvia will be generated, unless counteracted by the retarding or neutralizing effects of chemical agents. To all appearances the surface is clean, but this is not true of the deposit. It is intimately mixed with excreta forced out of numerous wells and impregnated with organic matter of various kinds borne in the sweeping flood. Under the influence of heat and moisture decomposition must rapidly take place, and the gases of putrefaction pollute the air. The free use of solutions of carbolic acid and sulphate of iron, and of chloride of lime in some cases, sprinkled over the surfaces and streets before and after the removal of the matter, will prevent the formation of unhealthy emanations, and aid greatly in the preservation of the health of the town.

The disposal of excreta will require the strictest sanitary supervision. Nuisances in this connection are likely to be created by the homeless ones and the population suddenly brought into the town who live in tents or improvised homes which have been located more with a view to convenience to the field of operations than to the hygienic advantages of the site. The regulations observed in a well-ordered camp are those which should be applied to the present exigency. The location of the latrines and their management should be such as to preclude any possible contamination of the water-supply or pollution of the air.

Disease is so frequently traced to inefficient modes of disposing of excreta, that it behooves the authorities of Johnstown to look well to the methods being adopted in the camps in its vicinity. The sites of the latrines being well selected, trenches should be dug twenty or more feet in length, ten feet deep, and two feet wide at the top and three feet at the bottom. The earth thrown out may be placed on three sides. Branches of trees or canvas may be arranged as screens. Chloride of lime and copperas should be regularly used, and nine inches of earth thrown in every day. When the soil is five feet from the top, the pit should be filled in and another dug, and the earth mounded to mark the spot. Tubs may be used as urinals, which can be emptied and disinfected each day. The soiling of the space about the camp should be prevented, and to this end a corps of scavengers should be organized to remove all surface filth and refuse, to attend to the latrines and urinals, and to destroy waste matter by fire. The sanitary policing of the district is a measure of imperative necessity. It will be advantageous to the health of the camp to change the site after a limited occupancy. Attention should also be directed to

the privies of the flood-swept part of the town, which may be only superficially covered by deposits left by the receding waters. The general water-supply seems to have been unaffected, but it should be carefully guarded. Wells in the inundated district may have been polluted, and should therefore be regarded with suspicion. The people should be cautioned not to use the water from the river in its present contaminated condition.

Sickness incident to exposure, fatigue, insufficient clothing, and improper food will doubtless be prevalent, but the admirable accommodations in hospitals and the generous provision made for medical treatment and for careful nursing of the sick and wounded by individuals and humane societies will be ample for every emergency.

There is need of improvement in the manner of housing the extra population, in the quality and preparation of the food, and in its distribution. Dependence should not be placed in the irregular and uncertain supply of commissary stores. Sickness is a common result of improper food, and therefore regular supplies of fresh meats, vegetables, milk, and bread should be provided for, and liberally furnished to the sufferers and to the laboring men, who are working under great disadvantages. Nutritious soups can be easily and quickly prepared, and should be a standard article on the commissariat's list.

The gravity of the situation can be greatly lessened by sending away temporarily the remnants of families deprived of their homes. Orphans can be cared for in the numerous institutions within the State. Kind friends are ready to provide for the wants of the homeless, if assisted to get away. The sick and injured able to travel have been invited by the open doors of many hospitals. This project has already been started in a small way, and should be followed up even to the extent of providing out of the general fund for their maintenance in adjoining towns. Relief will thus be afforded to the suffering ones and overcrowding prevented. The energies and labors of the organizations now aiming at the restoration of order out of chaos will thereby be greatly relieved of a pressure which impedes their efficiency. Idlers and curiosity-seekers are impediments, and are rightfully excluded from the town.

The destitute are fairly well clad. Much of the old clothing sent to the survivors being utterly worthless should be promptly disposed of by fire. Soiled clothing may disseminate disease, and it is the part of prudence to exclude it from distribution.

Intelligent coöperation of the various interests in the field, and thorough organization of the different branches of labor under a central authority, clothed with ample powers, are the need of the hour. By system, and only by system, intelligently and rigidly enforced, is rapid and unimpeded progress to be made in reclaiming the waste places and restoring the town to its inhabitants.

The suggestions which have been made are based upon thoughtful study of the sanitary aspects of the situation. If they are properly carried out we are sanguine enough to believe that much sickness will be prevented and further disaster averted.

Great credit is due to the State Board of Health for the prompt, energetic, and intelligent manner in which it has met the exigencies of the situation. Many of the sanitary measures which we have outlined it has already put into active operation, and the remainder, we doubt not, it will efficiently carry out so soon as time and resources will permit.

DR. C. K. MILLS and Dr. Thomas J. Mays, a Committee from the College of Physicians of Philadelphia and the Philadelphia County Medical Society to carry relief to the medical practitioners, sufferers by the flood, reached Johnstown on Monday. They found that six physicians were drowned and twenty-one had lost all they had. They will immediately expend about $3000 in the work, which has been subscribed by the profession of Philadelphia, and more money will be raised to continue it if required.

DR. J. H. MUSSER has been elected Assistant Professor of Clinical Medicine at the University of Pennsylvania.

WE are informed that the Warren Triennial Prize of the Massachusetts General Hospital, of $500, has been awarded to Drs. H. A. Hare and Edward Martin, of Philadelphia, for their essay entitled "The Functions of the Phrenic Nerve and the Best Methods of Artificial Respiration."

MRS. JANE C. STORMONT, widow of the late Dr. D. W. Stormont, of Topeka, has generously given $10,000 to the Kansas Medical Society for the purchase of a library for the benefit of the profession.

THE New York Post-Graduate Medical School will open a summer term on June 17th. The fees for this session are one-half those of the winter

term, while the advantages in the Dispensary of the School and in many of the Hospitals of the city are the same as during the winter.

DRS. IRWIN, FERGUSON, and HANCE, the physicians who performed an autopsy on the body of Washington Irving Bishop, the mind-reader, have been indicted for making the post-mortem examination without first obtaining the legal authority to do so. The penalty for this technical offence is imprisonment for not more than one year, or a fine of not more than $500, or both.

The District Attorney seems to have been disposed to let the matter drop, but Mrs. Bishop, the mother of the deceased, insisted on indictment. That Bishop was alive and in a trance when the autopsy took place no one but Mr. Bishop's immediate relatives appears now to believe. The Coroner's jury entirely exonerated the physicians.

THE Queen on the occasion of her recent birthday raised Sir William Jenner to the rank of the First Class, or Knight Grand Cross (Civil Division) of the Most Honorable Order of the Bath, which is said to be the highest distinction ever yet conferred by the British Crown on a medical man, and we cordially hope that Sir William may have many years' enjoyment of his deserved honor. On the same occasion the Queen conferred a baronetcy upon Sir George H. Porter, of Dublin.

DR. JAMES B. HUNTER, of New York, died at his residence in New York, last Monday, at the age of fifty-two, of acute rheumatism complicated with endo- and pericarditis.

Dr. Hunter was a native of Geneva, New York, received his medical education at the Ohio Medical College and immediately upon graduation in 1861 he entered the army and served as assistant surgeon, and later as surgeon of the 60th Regiment of Ohio Volunteers. For two years and a half, up to 1872, he edited *The New York Medical Journal* in conjunction with Dr. W. T. Lusk, and then for six years he was its sole editor. He was a member of the American Medical Association, of the County Medical Society, and of the Obstetrical Society of New York, and was connected with the Woman's Hospital since 1874, the Cancer Hospital, of which he was one of the founders, the New York Infirmary for Women and Children, and Professor of Gynecology and President of the Faculty of the New York Polyclinic.

SPECIAL ARTICLE.

MEDICAL NOTES FROM JOHNSTOWN.

PROFESSOR W. S. FORBES, of Jefferson Medical College, who organized and carried to Johnstown the first medical relief corps and stores to reach the flooded district and who only returned last Tuesday, has kindly placed in our hands the following brief notes of his medical observations while on the ground.

"In a visit to Johnstown immediately after the flood in the Conemaugh and Stony Creek Valleys on the 1st of June, I was very strongly impressed with the fact that by far the great majority of persons exposed to peril during the flood and who had escaped, had ecchymosis of the conjunctiva to a greater or less degree. The ecchymosis was very decided in very many persons and caused a great deal of suffering. The blood out of its normal vessels acted as a foreign body and caused many parties to seek professional relief.

"In the bodies of the dead the eyeballs appeared protruded as a general rule and the eyelids were opened wide. The bodies were considerably bruised. In one instance an arm had been torn from the body at the shoulder-joint and could not be found. In no case had decomposition progressed to any extent until about the sixth day. The temperature of the air was about 76° F. during this time, nor did it fall below 60° F. at any time. The sun was out only one day, the 5th; after the sixth day, on the exposure of the body decomposition was rapid.

"Nervous shock was a prominent feature among all the survivors. On hearing of the death of their relatives, several cases were so overcome that functional activity seemed paralyzed, nutrition was suspended, and death ensued.

"There were comparatively few injuries among the rescued, and they slight in character. It seemed to be, for the most part, either death or escape without injury.

"There has been thus far a remarkable freedom from all forms of sickness, in view of the exposure incident to the flood. On the sixth day I had heard of but a single case of pneumonia, and a few sporadic cases of measles.

"Six of the physicians of Johnstown were drowned —more than one-fourth of the entire number in the town. These men were lost in their endeavors to assist others to escape—and by their character and death illuminate the entire body of their profession. Dr. Brinkey was a conspicuous example of heroic devotion. He rushed again and again from safety into peril, urging the way of escape to many, until he was overwhelmed with a large party, whose bodies with his own were recovered under the débris of the Hurlburt House.

"As a type of the self-sacrificing devotion shown by the physicians of Johnstown toward the sufferers, we may particularize the case of Dr. W. B. Lowman, the founder of and surgeon-in-chief to the Johnstown Hospital. As soon as he had escaped from the débris of his home and rescued his family of eight persons, including his venerable father Dr. John Lowman, and many who had been caught and given refuge in his house as they were being swept by in the flood, he at once set to work on his further mission of mercy. He immediately despatched a messenger on horseback across the country to Somerset, some miles away, and was the first to summon by telegraph medical aid and stores from Philadelphia, and he has been constant and untiring in his personal labors and in the organization of medical relief.

"Dr. Matthews, another of the surviving physicians, early in the flood had two of his ribs broken, but, notwithstanding, remained with a large party of women in a house where they had been rescued and took charge of several of them who had premature confinements brought on by the tremendous strain on their nervous systems. I did not hear of the death of a single one of them. This entire party was rescued under Dr. Matthew's guidance.

"Of the surviving physicians, some lost members of their families and all nearly all of their worldly goods.

"The State Board of Health under the superintendence of Dr. Benjamin Lee, was promptly on the ground, and, although it was necessarily greatly hampered in the difficult problems it had to cope with, it rendered most efficient and valuable service in all matters relating to sanitary details.

"This catastrophe has developed in the afflicted region and in the country at large, a depth of generosity, a breadth of humanity, and an elevation of character that do honor to the human race.

"W. S. FORBES, M.D."

1704 WALNUT STREET, PHILADELPHIA.

SOCIETY PROCEEDINGS.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Eleventh Annual Congress, held in Washington, D. C., May 30 and 31, and June 1, 1889.

(Concluded from page 642.)

FRIDAY, MAY 31—MORNING SESSION.

DR. T. AMORY DE BLOIS, of Boston, read a paper describing

SOME OF THE MANIFESTATIONS OF SYPHILIS OF THE UPPER AIR-PASSAGES

and exhibited drawings showing the conditions which he had found.

DR. F. H. BOSWORTH, of New York, referred to the necrosis of bone which occurs in syphilitic ulcerations. He did not believe that syphilitic ulcerations extended from one part to an adjacent part. Such ulceration is due to the breaking down of a gummatous deposit, and does not extend beyond the limits of the original gummatous deposit. The necrosis of the bone he held to be due to the interference with nutrition of the bone, caused by the original deposit, and that after the breaking down of the gummatous infiltration has taken place, the ulceration is kept up by the necrosed bone, and treatment should therefore be directed to this point. He agreed with the author of the paper that potassium iodide was to be employed until the disappearance of the lesion, and that mercury should be used subsequently. Operative interference should be postponed until the syphilitic disease was well under control.

DR. C. C. RICE, of New York, said that in these cases there was often cicatrization and contraction above the visible adhesions, so that after the adhesions are freed, the results as regards phonation and respiration are not what would be expected. This contraction in the post-nasal pharynx requires to be stretched in order to obtain good results. In regard to operations, in one case where there were adhesions, and where there had been no syphilitic manifestations for many years, he applied the galvano-cautery to the adhesions. The ulceration which followed took on an unfavorable character, and continued to spread despite constitutional and local treatment.

DR. J. N. MACKENZIE protested against the too vigorous removal of diseased bone from the nasal passages. It frequently happens that more is pulled out than is desired, and sometimes from dangerous regions.

DR. WILLIAM H. DALY objected to the use of the galvano-cautery in tissues of the low vitality of syphilitic tissues. He believed that the galvano-cautery was a much abused, useful instrument. He felt satisfied that better results could be obtained in the fauces, in the nose, in the larynx, in any operation by using a sharp cutting instrument and allowing as free hemorrhage as is consistent with good judgment. The freer the hemorrhage within certain limits, the more certain is there to be immunity from septicæmia and rapid union.

DR. CHARLES H. KNIGHT, of Boston, then read a

NOTE ON THE GALVANO-CAUTERY IN THE TREATMENT OF HYPERTROPHIED TONSILS.

This paper was supplementary to one read two years ago. The galvano-cautery cannot be satisfactorily used in young children, and in them the guillotine is preferable. In older children and adults the galvano-caustic point will prove of service. The galvano loop was especially considered. With this the operation can be done at one sitting. The portion removed by the loop does not indicate the real extent of the operation. A portion of the remaining tissue sloughs, so that the operation with the loop is better than with cutting instruments. There seems to be little more pain with the galvano loop than with the guillotine. The former operation is, however, more disagreeable on account of the odor of burning flesh.

DR. T. A. DE BLOIS had used the electrolytic needle with good effect. Under cocaine, the pain of the procedure is very slight. Half a dozen punctures each day will in a short time produce great diminution. This

method is used only in adults. In children the tonsils are very apt to diminish in size without treatment.

DR. C. E. SAJOUS had frequently used the galvano-point, but had to make as many as eighteen or twenty punctures in order to obtain satisfactory results. After the second visit the patient expresses very little objection to the operation. The galvano-point is useful in the treatment of enlarged tonsils, especially where the density is not great. Here the cicatricial contraction assists in reducing the size.

DR. DALY believed that in the normal throat no portion of the tonsil extended beyond the line of the half arches, and in abscission of the tonsil our object should be to restore the throat as nearly as possible to its normal condition. This cannot be thoroughly done with the tonsillotome, but the operation must be completed with forceps and bistoury.

DR. F. H. BOSWORTH could see no reason for treating this condition by means of eighteen or twenty punctures when the whole trouble could be removed in a few seconds by a very simple operation.

DR. C. C. RICE believed that there are a few cases in adults where there have been frequent attacks of tonsillitis, and the tonsils are greatly congested, and in which the galvano-cautery is of service.

DR. JOHN O. ROE, of Rochester, then read a paper on

THE TREATMENT OF DISEASED TONSILS WHEN UNATTENDED WITH HYPERTROPHY.

The conditions referred to are of marked clinical importance, but their consideration is ignored by writers upon these subjects. The most common form of disease of the tonsil is hypertrophy, and in children it is rare to find any other form. During adolescence the tonsils may diminish in size, but they do not return to their normal condition. The small tonsils in adults have often followed hypertrophy. This is a point in favor of the removal of enlarged tonsils. The two forms of disease of the tonsil to which attention was called were : first, chronic disease of the crypts and lacunæ ; and, secondly, fibroid degeneration of the stroma of the organ—the cicatricial form of the disease. The first is the result of chronic follicular catarrh of the tonsil, and is usually associated with chronic follicular catarrh of the pharynx. The treatment of these conditions is important, not only on account of the disease itself, but also because they are the source of recurrent trouble, and may cause reflex symptoms. Local applications are practically useless. The galvano-cautery, which is useful in the treatment of hypertrophied tonsil, may be employed here, but is not as efficient as it is in the former condition. The treatment *par excellence* is ablation with the knife. The diseased crypts may be laid open and cauterized with chromic acid or fused nitrate of silver. Excision is, however, the best plan. It is rarely advisable to attempt removal of the whole mass at one time, on account of the adhesions to the pillars. The use of cocaine lessens pain and hemorrhage. In every instance in which the speaker had employed excision the cure had been perfect, with entire relief from the attendant symptoms.

DR. H. L. SWAIN, of New Haven, reported a case in which recurrent attacks of swelling of the lingual tonsil were caused by the presence of hard masses in the faucial tonsils. The attacks were subdued by treatment of the crypts by cutting into them with the galvano-cautery, and thoroughly cauterizing their interior.

DR. J. SOLIS-COHEN, of Philadelphia, had seen many cases of spasmodic cough, due to nothing but the presence of these masses in the crypts and lacunæ of the tonsil. These had been found not only in the enlarged but also in apparently contracted tonsils. It is sometimes necessary to produce some gagging, so that the posterior portion of the tonsil presents, in order to discover this condition. In enlarged tonsil, the best treatment is probably excision, but in these atrophied tonsils he had pressed the matter out with a blunt scoop, and then applied a simple astringent consisting of creasote, gr.j ; iodine, gr.j ; potassium iodide, gr.v, to glycerine, ℥j. If this does not answer, he cuts the crypts open with scissors, and scrapes them as thoroughly as possible. This affection is not as thoroughly appreciated by the profession as it should be. He had seen cases where cough existing for five to ten, or more, years, had been permanently relieved by treating this condition.

DR. DALY referred to cases in which the patients were really sick as the result of these lacunæ becoming filled with cheesy matter.

DR. F. I. KNIGHT described a case of long-continued irritative cough, in which the removal of a cretaceous mass as large a pea from a crypt of the tonsil was followed by complete cure.

DR. SAMUEL JOHNSTON, of Baltimore, referred to three cases in which the collection, instead of consisting of soft cheesy material, was hard, looking like spicules of bone, and adhered with great intensity. These bodies were not limited to the tonsil, but were also found on the lower part of the fauces, and on the post-pharyngeal wall.

DR. HARRISON ALLEN stated that he had referred to this condition in a paper published in 1882. The solid matter is retained in the crypts. This pressure is often produced by the anterior fold. Sometimes the secretion has gotten out of the tonsil, but is still retained behind the fold. More frequently these masses are beneath the tonsil, under an adventitious membrane.

DR. J. SOLIS-COHEN reported

A CASE OF SARCOMA OF THE THYROID GLAND.

The case was one of sarcoma of the thyroid gland, with pressure on the right sympathetic nerve ; unilateral tonic spasm of the laryngeal muscles ; intermittent clonic spasm of the muscles of the opposite side. There was stenosis from the pressure of the tumor. For this, tracheotomy was performed. This afforded relief for a number of months. Hemorrhage occurred twenty months later, but was controlled without much difficulty. Gradually marked disturbance of the two pneumogastrics supervened and there was great interference with respiration. It was accidentally discovered that any irritation of the mucous membrane of the trachea would relieve the dyspnœa, and at once the lividity of the face would disappear. This effect was readily produced by tracing the posterior wall of the trachea with a bent wire passed through the tracheotomy tube. The patient died of exhaustion.

SATURDAY, JUNE 1.—MORNING SESSION.

DR. C. C. RICE read a paper on

SOME UNUSUAL MANIFESTATIONS OF TUBERCULOSIS OF THE LARYNX.

The first unusual manifestation referred to was where

syphilis and tuberculosis of the larynx coexist. Here the lesions of one process mask those of the other. Here the prognosis depends upon which is the more active condition. This combination is more common than is generally supposed, and probably some cases of cure of supposed tuberculosis should be placed under this head. A second unusual manifestation is the engrafting on the tuberculous process of a new tissue, rendering the diagnosis difficult. This new tissue may be of two forms, either a granulation tissue or a papillomatous growth. The third condition was adhesive inflammation at the anterior ends of the vocal bands. This must be rare, as the tubercular process shows little tendency to cicatrization and healing. It is liable to occur only when the cords are immovable and there is general proliferation of tissue. The last condition referred to was one in which the tubercular deposit in one arytenoid was the only manifestation of the disease in the larynx, the remaining parts of the larynx being perfectly normal.

DR. W. H. DALY was satisfied from his experience in three or four cases, that in some instances tubercular ulceration of the larynx may be cured. In these cases there was no evidence of syphilitic disease, and in at least some of them the tubercle bacilli were found. Recovery has followed the use of alkaline sprays and inhalations with the free use of iodoform. He believed that tuberculous ulceration of the larynx might occur without evidence of tubercular deposit elsewhere.

DR. J. C. MULHALL, of St. Louis, thought that there might be a catarrhal ulceration of the larynx, and that this was a curable condition. He did not think that it would be easy to prove that tubercular disease of the larynx was ever primary, although it is sometimes the first sign of the condition. In tubercular ulceration of the larynx he had used pure lactic acid and had seen the ulceration heal, but he could not say that he had ever seen life prolonged to any appreciable extent.

DR. F. I. KNIGHT had not the slightest doubt that tubercular ulceration of the larynx does get well. He had seen such ulcers heal under alkaline sprays and iodoform, and more especially under lactic acid. He thought that it was possible to have the tubercular disease of the larynx as a primary affection, but in the majority of cases careful examination will reveal evidence of disease of the lung. He did not regard changes in the respiratory murmur and in respiration as the most important signs of early phthisis. He placed more reliance upon the localized râles which are heard on coughing. In order to develop this sign the patient should not inspire immediately before or after the cough, but should cough from a rest. He had seen but a few cases in which he regarded the disease as primary in the larynx.

DR. W. E. CASSELBERG, of Chicago, reported a case in which he found catarrhal ulceration of the larynx, which readily healed under cleansing treatment, and there has been no return of the ulceration during a period of two years.

DR. J. N. MACKENZIE thought that the question of the possibility of the existence of primary tubercular disease of the larynx had been settled by examinations upon the post-mortem table, where, in a few cases, careful examination of the body revealed tubercular deposit nowhere but in the larynx. While a tubercular ulceration of the larynx may heal, this by no reason indicates the cure of the disease. He had seen the coexistence of syphilis and tuberculosis in the larynx several times, and it is difficult to say which is the syphilitic and which the tubercular ulceration. The only test is that of treatment. He had never seen what could be called catarrhal ulceration of the larynx. In regard to treatment, he thought that more harm than good was produced by the employment of harsh measures. There is a form of ulceration which occurs in the later stages of phthisis principally near the bifurcation of the trachea, which is probably due to the corrosive action of the sputum.

DR. W. C. GLASGOW believed that tubercular ulcers of the larynx never healed. He had seen cases of ulceration of the larynx heal under simple treatment, but he did not consider these to be true tubercular ulcerations. He had used with great satisfaction during the past two years the peroxide of hydrogen in the treatment of such ulceration, and under its use there is rapid healing. He did not believe in primary tubercular disease of the larynx. In all the cases that he had seen there had been more or less disease of the lungs. In true miliary tuberculosis of the larynx he had always found some evidence of the disease in the lung, and these cases he thought never recovered. He had seen cases of catarrhal ulceration of the larynx.

DR. S. SOLIS-COHEN, of Philadelphia, read a paper on

THE OCCASIONAL TOPICAL USE OF SOLUTIONS OF NITRATE OF SILVER IN THE TREATMENT OF CHRONIC LARYNGITIS.

The cases reported were not due to nasal disease or obstruction; nor were they those in which all topical treatment is unnecessary. Where indigestion, constitutional disease, or diathesis have been present these have received due attention. It was simply of topical applications for the relief of local conditions that he spoke. All have encountered cases of chronic laryngitis, especially in singers, clergymen, lawyers, etc, in which, after all discoverable sources of irritation, local or general, have been removed, and approved topical treatment suited to the individual case has been faithfully tried for a longer or shorter time, improvement takes place to a certain point and then stops. Perhaps all visible evidences of disease, except an irregular, pinkish striping of the vocal bands have disappeared, or perhaps there would be a faint uniform coloration, or may be only a loss of lustre; but something there would be that persisted and that prevented the patient from resuming with comfort full use of the voice in singing or speaking, or perhaps even in ordinary conversation.

It is in such conditions as these—the last obstinate remnants of the disease—that he derived considerable satisfaction from the topical use, by sponge, cotton wad, or brush, of weak solutions of silver nitrate, about ten grains to the ounce, applications being made every day for some two or three days until some congestive reaction is produced; after that at longer intervals. In the course of treatment, too, in some cases before reaching the last stage above described, he had found recovery apparently hastened by occasionally substituting stronger solutions of silver nitrate, forty to sixty grains to the ounce, for the iodized glycerine, tannin, tar, or other routine application. A visible increase in congestion immediately follows the use of the silver solution; but this passes off quickly, and at the next visit great improvement is usually manifested. These applications

are made once in about two or three weeks, according to circumstances.

DR. C. E. BEAN, of St. Paul, described two cases of

TUBERCULOSIS OF THE TONGUE,

one in a male and the other in a female. In both the disease had made extensive progress when they came under observation, and no operative measures seemed warrantable. In both there was well-marked involvement of the lungs. Death occurred in both cases a short time later. Attention was called to the differential diagnosis between tuberculosis, carcinoma, and syphilis. Carcinoma is to be excluded by the absence of granular enlargement and by the lancinating pains peculiar to that disease. The question of syphilis can only be determined by the history and by the effect of anti-syphilitic remedies.

DR. J. C. MULHALL then read a paper on

THE LOCAL TREATMENT OF DIPHTHERIA.

The method of treatment which he suggested was based upon the following considerations: 1. That diphtheria is a germ disease. 2. That the specific microbe in the majority of cases selects the tonsils. 3. That unless checked by treatment the colonization of these germs results in local putrefactive changes with subsequent involvement of the general system. 4. That implication of the larynx or of the nasal passages increases the mortality. 5. That the disease is acutely adynamic. It had occurred to him that in this disease it would be better to wash out the throat than to spray it. This is accomplished by means of an ordinary syringe, and in this way the throat can be washed out without difficulty. The patient should be kept in the recumbent position, the head being brought to the edge of the bed. This procedure is repeated every hour during the day and at no time is a longer period than three hours allowed to elapse. The only solution that he has used has been carbolic acid with compound solution of iodine. The water is frequently saturated with boracic acid.

The post-nasal space requires careful attention. In every case of diphtheria the nasal cavities should be kept sterile from the first. When it is certain that the nasal cavities are not affected the insufflation of a non-irritating, antiseptic powder may be sufficient. Where there is uncertainty or where it is certain that infection has taken place, the nasal cavities are to be washed out with a weaker solution of the same kind, not more than a teaspoonful for each nostril. For this purpose he recommended a small glass syringe with a bulbous extremity to prevent injury to the nose. After cleansing he frequently resorts to solvents, and has obtained the best results with papoid. In laryngeal diphtheria inhalation is the only practicable method. The inhalation of the vapor from slaking lime should not be forgotten. In several cases of laryngeal diphtheria he had obtained good results by placing the patient in a small room which had been fumigated with sulphur, and by keeping water to which had been added pine-tar and turpentine constantly at the boiling-point.

DR. W. C. GLASGOW believed that diphtheria is a blood disease rather than a local affection, and that the only objects in local treatment are cleanliness, disinfection, and loosening of the membranes. One remedy which he had used with advantage was the peroxide of hydrogen in spray. It seems to act by lifting up the membrane by the formation of gas. He considered the constitutional treatment as the most important, and he thought the bichloride of mercury and benzoate of soda were the most successful remedies. With these he uses very simple local treatment. In cases of severe local manifestations the method described by Dr. Mulhall would be valuable.

DR. D. BRYSON DELAVAN referred to the value of the bichloride of mercury and cyanide of mercury, which he had used for ten years in the treatment of diphtheria.

DR. W. H. DAILY had on previous occasions recommended the use of calomel in the treatment of this affection, and he thought it was as efficient as a local agent as it was active as a constitutional remedy. He believed that calomel in large and frequently repeated doses—two, three, four, or five grains to children one to two years of age—exerted a valuable therapeutic effect. He thought that a large part of the effect was from the local action upon the diphtheritic poison.

DR. HARRISON ALLEN referred to the value of trypsin as a solvent for the diphtheritic membrane.

DR. F. WHITEHILL HINKEL, of Buffalo, then read a paper on

SOME MANIFESTATIONS OF LITHÆMIA IN THE UPPER AIR-PASSAGES.

The influence of lithæmia and allied conditions upon the upper air-passages has received little attention in laryngology, as is shown by the scanty literature extant upon the subject. There is a distinction to be made between distinctly gouty sore throat and that due to lithæmia or some allied condition. The subjects of the latter may never have attacks of true gout, nor irregular manifestations of it; indeed, as a rule, they are not so affected. The term lithæmia is elastic in its application to cases varying from extreme digestive and nervous disturbance to almost normal health; consequently its manifestations in the upper air-passages are not sharply distinguished, nor are they typical or pathognomonic. One of the most characteristic manifestations is a patchy or striated irregular congestion of the mucous membrane of the larynx and pharynx. In the former case a dry explosive cough accompanies, in the latter uneasiness or positive pain is referred to the side of the throat, occasionally extending to the ears. These cases are notably irritated and made worse by stimulant applications. Local sedatives and general antilithic treatment give the best results. Occasionally acute naso-pharyngeal catarrh is a manifestation of an exacerbation of the lithæmic tendency. Alkaline and diluent medication with proper diet give more relief than local treatment. Obstinate relaxation of the venous plexuses of the turbinated bodies in some individuals appears associated with lithiasis. Such cases stand operative—caustic—applications badly, and receive little or no benefit from them. Some of these cases are much improved by antilithics and general hygiene. Others are intractable on account of uncontrollable lithæmic tendencies.

At the executive session the following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—J. N. Mackenzie, M.D., of Baltimore.

Vice-Presidents.—Edgar Holden, M.D., of Newark, and C. E. Bean, M.D., of St. Paul.

Secretary and Treasurer.—C. H. Knight, M.D., of New York.

Librarian.—T. R. French, M.D., of Brooklyn.

Council.—Franklin H. Hooper, M.D., of Boston; George M. Lefferts, M.D., of New York; Frederick I. Knight, M.D., of Boston; D. Bryson Delavan, M.D., of New York.

Representative on the Committee of the Congress of American Physicians and Surgeons.—Harrison Allen, M.D., of Philadelphia.

The following were elected *Members:* Wm. E. Casselberg, M.D., of Chicago; H. L. Swain, M.D., of New Haven.

The Association then adjourned to meet in Baltimore, the time to be determined by the Council.

CONGRESS OF THE GERMAN SOCIETY OF SURGERY.

Eighteenth Annual Session.

Held at Berlin April 24th to 27th, 1889.

(Specially reported for THE MEDICAL NEWS.)

(Continued from page 615.)

DR. OPPENHEIM, of Berlin, made some remarks

ON TRAUMATIC NEUROSIS.

Frequently after a very severe traumatism, patients who have been treated by a surgeon are obliged to go to a physician, for the reason that, after their injury, a traumatic neurosis has developed itself. These post-traumatic neuroses are very interesting to physicians, but are no less important from a sociological point of view. When a workman sustains an injury during his occupation, his employer owes him compensation for his treatment, but if, after the wound or injury has been cured, a traumatic neurosis arises, who is to be responsible, the workman or the employer? To be able to determine in such cases who is to pay the damages, we must know in what these neuroses consist, whether they are the result of the traumatism, or, on the contrary, are the manifestations of an anterior nervous state which reveals itself on the occasion of the injury. In the first case, the employer would really be responsible, while in he second it would be the workman. Before settling the question of the nature or cause of these traumatic neuroses, a careful study of cases is necessary.

1st. A railroad employé was struck on the left shoulder by a wagon. A very large ecchymosis appeared in the shoulder and clavicular region. A few days later, paralytic symptoms appeared. The left arm was slightly cyanosed, and the back of the hand was œdematous. The arm could not be raised, sensibility was lost in the left hand and weakened in the left half of the body. The conjunctiva and cornea of this side were insensible, the visual field was very much shortened, taste and smell were diminished on the same side. There was a paresis of the left lower extremity. The tendon reflexes were somewhat more pronounced than normal; electrical excitability was diminished in the left arm. The patient also presented certain psychical symptoms.

2d. A railroad employé was caught between two cars and sustained an injury of the right shoulder. Later, the right arm became contracted, the elbow flexed, and the fingers assumed the position of holding a pen; when the patient tries to extend them they show a marked trembling. The patient feels severe pain in the shoulder, which becomes exaggerated when the arm is to be moved. There is no reaction of degeneration, sensation is completely abolished in the hand and diminished on the right side. Anæsthesia also involves the organs of sense; there is a shortening of the visual field on the right side. The right inferior extremity is in a state of paresis, but the patellar reflex is exaggerated. The intellectual powers are also depressed. The tongue is deviated to the right, and more so than in ordinary hemiplegia.

3d. A man received in 1886 a series of shocks in the sacral region from a moving pendulum. Later the patient complained of severe pain in this region, followed by a persistent trembling of the whole body, which trembling is exaggerated by movements. He maintains with difficulty his trunk in position when he wants to pick up an object, for example; the inferior extremities are, at the same time, stiff and feeble. In this case, as a result of a localized traumatism, there has been produced a general nervous disease; words are expressed in a trembling voice, syllables are spaced in a peculiar manner which has not yet been noted in nervous diseases. The pulse is rapid; 90 in repose, but goes up to 140 when the patient moves. This acceleration of the pulse is very important. There is in this patient an analgesia of the skin covering the cranium, which extends even to the eyebrows. This patient is very much agitated, very irritable, and cannot sleep.

4th. A patient was injured on the head by the falling in of a cave; the immediate injury sustained was easily cured; but later, nervous phenomena presented themselves. The patient suffers from interference in his speech and in his walking; he has vertigo; presents Romberg's sign. He stammers. His walk presents characteristic signs; the patient easily advances the right foot, which then falls, striking the ground; to bring the left foot in front of the other, instead of making an ordinary step, he is obliged to take a great many short steps.

5th. An engineer fell, in 1885, from a locomotive, and was unconscious for some time after the fall, and then remained for several months in a bad cerebral condition. Then occurred a right pleurisy. To-day, the patient presents all the symptoms of a generalized neurosis. He is excited, troubled, and has continuous nervous palpitations; pressure on the right side of the thorax brings on violent pains. The patient complains of confused ideas and intellectual weakness.

Formerly, to explain such facts, an organic lesion of the nerve centre, due to the traumatism itself, was suspected. But, as a demonstration of these hypothetical material lesions could not be given, certain authors thought that the patients were only simulating, so as to be able to profit by their accident. To-day, our methods of diagnosis allow us to expose the simulators, and we must admit that a traumatism can develop a neurosis without organic lesions, and analogous, for example, to hysteria. But is this neurosis hysteria itself, or is it a special neurosis? To know it, we must compare traumatic with hysterical neuroses, and see whether we can find characters which allow us to establish a differential diagnosis.

He thought that there are signs distinctive of these two neuroses. Traumatic neuroses are accompanied by psychical phenomena which are not found in hysteria.

In cases of traumatic neurosis, traumatisms which have occurred in one region of the body can determine nervous symptoms on the opposite side. Traumatisms of the sacral region not only determine paraplegic phenomena, but these symptoms may extend further up, and may become generalized in the whole nervous system. Likewise, an accident which occurs on one extremity can produce a general neurosis. These neuroses never give rise to the reaction of degeneration. They can be produced as a consequence of muscular atrophy with diminution of the electric hyper-excitability, but these symptoms are generally not much developed. The prognosis of these traumatic neuroses is sometimes difficult to express; it must always be reserved, and is more often unfavorable than favorable.

DR. LANDERER, of Leipzig, read a paper

ON THE DRY DRESSING OF WOUNDS.

He now very seldom uses any antiseptic agents; following Sänger's rule, all his instruments are first thoroughly boiled in water; he then places them in a plate containing a two per cent. carbolic acid solution. In private practice, and especially in country practice, it is not easy to procure antiseptic agents.

He uses during the operation the 1 to 1000 sublimated gauze, and after the operation is completed the wound is packed with the same, and so heals by first intention. He had a record of over ninety large and small operations without any failure.

DR. BRAMANN, of Berlin, then made some remarks on

SYMMETRICAL GANGRENE OF THE EXTREMITIES,

and presented three brothers, seven, nine, and thirteen years old respectively, all suffering from symmetrical gangrene of the extremities, a disease known by the description given by Raynaud in 1862. In the beginning these patients suffered from local syncope and local asphyxias. The ears and hands are anæmic and chlorotic; no hereditary antecedents; no arterio-sclerosis. The youngest was seen in his fourth year; his thumb became tumefied and the nail fell off. The oldest has lost a phalanx of the index of the left hand. The nails of the toes are very curved, and he has lost two phalanges of one of his toes. The third one suffers from anæsthesia of the whole arm and presents an ulcer on the plantar region of the foot. In all these patients sensation is abolished in the fingers and diminished in the lower extremities. He thought that this disease is attributable to a disease of the spinal cord.

DR. KOENIG, of Göttingen, had observed in a patient, after typhoid fever, symmetrical gangrenous plaques on both hands and on the sternum.

DR. BRAMANN said that after acute diseases, such as typhoid fever and other diseases of the same kind, we are liable to observe acute gangrene. This disease cannot be confounded with symmetrical leprosy, because of the lack of symmetry of anæsthetic leprosy, which, moreover, presents an anæsthesia in plaques.

DR. FISHER said that, in his opinion, symmetrical gangrene was a trophic disorder, for it is found in wounds of mixed nerves.

M. SOCIN, of Bâle, thought that in the majority of cases we have to deal with a nervous affection; yet symmetrical gangrene can be produced by other causes—for instance, he had observed it in an anæmic child of four months; in two days the gangrene had become so extensive that he was compelled to amputate both feet and both forearms. The child is now doing very well. In this case he attributed the symmetrical gangrene to thrombosis following endocarditis.

DR. THIERSCH had in his clinic a similar case; all the ten fingers were anæsthetic, and he had also two patients suffering from syringomyelia who presented certain phenomena of symmetrical gangrene of the extremities.

PROF. WAGNER had observed a symmetrical gangrene on the back of a man, aged thirty-five; the disease when it began had all the appearance of zona.

DR. HANAU, of Zurich, then read a paper

ON THE INOCULATION OF CARCINOMA IN ANIMALS.

Although carcinoma is a tumor which produces metastasis, it has always been impossible up to now to inoculate it from man to animal, or from one animal to another. There has been an attempt to transport carcinoma from a dog to another dog, and even to rabbits or guinea-pigs; but these experiments have given us no results. He had succeeded in inoculating carcinoma from a rat which was suffering from papillary cancroid to two other animals of the same species. These two rats had been inoculated in the tunica vaginalis of the scrotum, which in these animals communicates with the peritoneum. At the end of seven weeks one of the rats died of carcinoma. The whole epiploon was covered with nodosities, some of the size of a pea, the others much smaller. The axillary and inguinal glands were involved. These tumors, examined microscopically, presented the same type as the inoculated carcinoma. The post-mortem examination of the second rat was made in the presence of Prof. Koch; this animal also presented the same alterations.

DR. RINNE, of Greifswald, had inoculated a carcinoma of the rectum in a dog to five other dogs. These inoculations were made in the subcutaneous and muscular tissues, and into the peritoneum, but he had obtained no cancerous transmission.

PROF. HEIDENHAIN spoke of an experiment in which the inoculation of cancerous fragments produced a cancerous alteration in the neighboring ganglions.

DR. HAHN, of Berlin, said that two years ago he transplanted in a patient, suffering from incurable cancer, a carcinomatous nodosity to a healthy part. This nodosity developed and was surrounded by new nodosities, which acquired three or four times the dimension of the primary nodule. The histological examination of these nodosities showed that they were carcinomatous.

DR. HANAU said that in a thesis by a Russian physician, M. von Norvinski, on the transplantation of cancer, experiments were reported on forty-two dogs, two of which proved successful; he, however, did not think it necessary to mention them, as several competent authors have considered those results as being questionable. It is possible that Norvinski had experimented on young animals, while he inoculated old ones.

DR. MEHR, of Lemberg, presented a dog which died from carcinoma as a result of inoculation made with cancer of human origin. The peritoneal cavity was filled with tumors from the size of a nut to that of an apple; the lymphatic glands were all involved, and the spleen presented a few nodosities. Also two other dogs, which

he inoculated on the 16th of February. They have on the abdominal parietes nodosities of a large size, and easily made out by palpation.

DR. F. KRAUSE, of Halle, then spoke of the

AFTER-RESULTS OF THE ABLATION OF CANCERS OF THE TONGUE.

In Volkmann's clinic, 91 carcinomas of the tongue have been removed during the past fourteen years; 35 of these were operated by sawing laterally through the inferior maxillary, according to Langenback's method; 56 have been operated upon without resection of the inferior maxillary. In this process the maxillæ are separated one from the other by a very strong stretcher. The epiglottis protecting the entrance to the larynx, one need not fear the obstruction of the trachea by blood. The lingual artery is cut between two hemostatic forceps; as to the other vessels they are cut and ligated one after the other, just as they present. Of the 35 operated upon in whom the ganglia were involved, 6 disappeared; 1 died from the disease; 3 have recurred at the end of three years; 2 have remained cured for the past six years.

DR. HAHN observed that an error of diagnosis in cancer of the tongue is not of unusual occurrence.

PROF. KÜSTER, of Berlin, said that two years ago he operated upon an ulcerated tumor of the tongue which he had taken for carcinoma; but the histological examination not confirming his diagnosis, he prescribed a treatment by iodide of potassium, thinking he might have to deal with syphilis, especially as he felt an enlarged gland in the region of the neck. As the gland did not disappear, he decided to remove it, and on microscopical examination it proved to be cancerous. This patient died two months later from generalized carcinoma.

DR. SCHEDE, of Hamburg, had operated on a patient for carcinoma of the tongue. The first time he took away the left side, the right side being healthy. In 1884 the right side also became diseased; he extirpated it, and the patient has remained well up to date. He had operated upon two other carcinomas of the tongue which were not followed by a return of the trouble; one was a cancroid.

PROF. VON ESMARCH said he operated twenty years ago on a patient in whom he removed the whole tongue; the disease never returned.

PROF. KÜSTER, of Berlin, presented a case of carcinoma of the tongue upon which he operated in 1879, and which has not returned since; the patient is able to speak quite distinctly. Out of 26 cases operated upon, 2 died as a result of the operation, and 3 remained without a recurrence for over three years.

Two years ago he operated upon a carcinoma of the tongue, which presented several recurrences; he operated five times on the same patient, who to-day seems to be cured. If the disease returns, its repeated removal will always prolong the life of the patient. In another case of carcinoma, which had been operated upon eighteen months previously, by Professor von Bergmann, he completely extirpated the organ as well as the diseased glands as far as the jugular region.

PROF. VON BERGMANN, of Berlin, presented two patients; one was a case who was operated upon two years previously, and the other four years before; the disease has not yet returned.

PROF. KRAUSE then spoke of the

AFTER-RESULTS OF EXTIRPATION OF CANCER OF THE RECTUM.

He presented three patients who had been operated upon for carcinoma of the rectum, six, eight, and nine years ago respectively. The disease has not yet returned in any of them. In von Volkmann's clinic he found four cases who have not recurred, and who had been operated on in 1881, 1883, 1884, 1885; in all, seven cases probably cured in a permanent manner out of seventeen patients. In the three subjects whom he presented, the peritoneal cavity was opened very freely, and in each the sphincter ani had been removed; the patients can no longer retain liquid feces, but only solid.

PROF. KÜSTER presented a patient upon whom he operated for carcinoma of the rectum by Kraske's method, with a splendid result as regards the preservation of the function of the sphincter.

PROF. VON BERGMANN presented a case of rectal carcinoma, operation by the "high amputation" four years ago, who has not yet shown any signs of returning disease.

RESULTS OF EXTIRPATIONS OF CANCER IN DIFFERENT REGIONS.

PROF. VON BERGMANN then presented several cases, amongst which was one of carcinoma of the pharynx operated upon in 1884; three months later the disease returned; all the glands were then removed, and the patient has shown no sign of the disease since the last operation. Another case was of carcinoma of the face which has remained cured for four years; and finally, two cases of carcinoma of the lips, operated upon two years ago, in which the disease has not yet returned.

DR. HAHN, of Berlin, presented a patient who had been operated upon for carcinoma of the larynx eight and a half years ago, but the disease has returned during the past two months.

PROF. VON BERGMANN presented a patient upon whom he operated for carcinoma of the larynx, removing one-half of the organ, four years and a half ago; no recurrence has taken place. The voice is slightly altered; the patient does not wear an artificial larynx.

As a parallel to this case, he presented a patient of Dr. Schmidt, from Frankfort-on-Main, who was operated upon three years ago, the entire larynx having been removed, and yet all are able to understand his speech.

DR. ROERTÉ, of Berlin, presented a case of carcinoma of the larynx operated upon two and a half years ago; the disease has not yet returned.

PROF. B. FRAENKEL, of Berlin, operated, in 1886, on a patient for carcinoma of the larynx, by the bucco-laryngeal method; the patient is well.

DR. SCHMID, of Stettin, presented a patient operated upon two years and a half ago, the entire larynx having been removed. No return up to date, and the patient is able to speak without an artificial larynx. He respires by a canula; in this patient the trachea is completely separated from the bucco-pharyngeal cavity. The preservation of the voice can only be explained by great narrowing of the pharynx, due to a contraction of the muscles, aided by large tonsils.

DR. SCHINZINGER, of Freiburg, had operated on eighty-six cases of cancer of the breast; twenty-six of them recurred in from one and a half to two years. He asked the question, whether one could not obtain an atrophy of the gland by castration.

PROF. HELFERICH, of Greifswald, then read a paper

ON PARTIAL RESECTION OF THE SYMPHYSIS PUBIS,

and presented a patient operated upon five years ago for carcinoma of the upper portion of the bladder. The tumor was adherent to the upper border of the symphysis pubis, and compelled him to resect a part of this articulation so as to be able to remove the tumor. After having extirpated the cancer, the borders of the wound of the bladder were refreshened before uniting them again.

PROF. MOSLER, of Greifswald, then presented a patient suffering from

MYXŒDEMA.

All internal treatment had been tried to ameliorate the disease, but without any result. There was no family history as to this particular disease the mother was epileptic. Her children died very young from meningitis; she has never had syphilis; as regards etiology, it was only found that the patient caught cold in taking a foot-bath. She experiences a well-marked interference in her speech, as well as in her movements; pain on pressure; the eyes are puffed up and the patient can hardly open them; the lips are tumefied; no physical lesions apparently of the heart or lungs. The blood contains white blood-corpuscles in excess; urine normal. A fragment of skin examined by Professor Grawitz gave negative result from a bacteriological point of view, as well as regards the alteration of the tissues.

PROF. HORSLEY presented a preparation of myxœdema; the patient died of an intercurrent disease. The thyroid body was small and presented numerous tracts of connective tissue. The subject died in the first phases of the disease, but if it were a case of death by myxœdema, the whole thyroid body would have been transformed into connective tissue.

DR. RINNE observed a very marked case of myxœdema, and thought that this disease can be well placed by the side of acromegalia or cretinism. As to the disease itself, it remains an enigma both as regards etiology and therapeutics.

DR. THIERSCH read a paper on

EXTIRPATION OF NERVES.

It is well known how difficult an operation it is to remove certain nerves, and especially the trigeminus. To obviate these difficulties he has had special forceps made, which allow the twisting of the nerve on its axis before tearing it away. For the past five or six years he has applied this process twenty-eight times on seventeen patients. In five cases the supra-orbital nerve was the one involved, eleven times the infra-orbital nerve, three times the lingual nerve, four times the submaxillary, once the labial and auricular nerves.

PROF. HORSLEY had resected the trigeminus fifteen times for neuralgia, and in one-third of his patients he had had a complete success. In those in whom the disease has recurred he has cut the nerve on a level with the foramen rotundum and foramen ovale. Once he tried to extirpate the Gasserian ganglion, but he had to give the operation up on account of the large hemorrhage. He thought, however, that most of these affections are of peripheral origin.

DR. THIERSCH had also practised resection of the fifth nerve at the foramen rotundum and foramen ovale after trepanation, but it is a most difficult operation, attended by great danger. He had also tried to extirpate the Gasserian ganglion, but had not succeeded, as a part of this ganglion is strongly adherent to the dura mater. He agreed with Mr. Horsley that these affections are of peripheral origin, yet he had observed a few that were certainly central.

DR. SENDLER, of Magdeburg, then presented a woman suffering from

CAVERNOUS ANGIOMA OF THE MAMMARY GLAND,

with a short pedicle. It is a polylobed tumor, divided into two halves by a deep fissure covered with normal skin. It greatly increases in size during menstruation. This case is an interesting one, on account of the unusual seat of the tumor; in fact, Virchow's *Archiv* and Billroth's compendium contain no example of it.

PROF. KRAUSE then read a paper on

RESECTION OF THE HIP-JOINT.

Out of three hundred and seven resections made at Prof. von Volkmann's clinic, two hundred and seventy were performed for caries, according to Langenbeck's method. The plaster dressing is abandoned, compression is employed, and an extension apparatus made with bands of adhesive plaster, which go as far up as the Fallopian ligament. Counter-extension is produced by the sinking of the pelvis into the bed. In severe cases only is counter-extension by weight necessary, when there exists a notable shortening; weights of twelve to twenty-five pounds are employed, according to the age or gravity of the case. Extension must be continued for years, even after the cure and straightening of the limb, by means of von Volkmann's stringed stocking, which is to be applied at night only.

Partial movements must be encouraged very early, and the patient may be allowed to get up at the end of three to four weeks; high heels are not employed, but in grave cases an orthopedic apparatus which maintains the limb in a state of abduction is prescribed. He showed a boy of fourteen years on whom he had operated; the head of the femur was necrosed and detached from the body of the bone; there existed a shortening of six and a half inches; there is now a complete correction, and the articular movements are nearly normal. The patient wears continuously the apparatus mentioned.

(To to continued.)

CORRESPONDENCE.

THE CULTIVATION OF ANAEROBIC BACTERIA.

To the Editor of THE MEDICAL NEWS,

SIR: In the course of investigations it happens not infrequently that investigators, pressed by the same needs, will hit upon practically the same method independently of each other. Permit me to call attention, somewhat

tardily, to such a coincidence. In your issue of March 30th, p. 347, Dr. Jeffries describes a new method of making cultures of anaërobic bacteria by filling the culture tube with mercury and inverting it over a reservoir of mercury. He thus drives out the air, and any gases that may be formed are retained. Dr. Escherich (*Die Darmbakterien des Säuglings*, p. 122), as long ago as 1886, made use of the same device and for the same purposes, with the exception only that liquid media of varying chemical composition were employed.

He sterilizes the mercury, with it fills a strong sterile test-tube, inverts it over a beaker containing sterilized mercury, and then transfers, by means of a curved pipette, the culture medium which has been previously inoculated with the desired microbe. The liquid, of course, rises to supplant the mercury in the test-tube. Some of the culture liquid is retained in the original flask as an aërobic control culture. The purity of the culture was always tested by removing, with a suitably curved pipette, some of the liquid and submitting it to a microscopic examination, or else by testing on gelatine after the experiment was completed. The author claims that contamination of the culture was very rare. The writer has not tried this method, but uses to determine the formation of gases in liquid media a simple device, which will be described at an early date.

THEOBALD SMITH.

NEWS ITEMS.

American Climatological Association.—The Sixth Annual Meeting of this Association will be held in the Boston Medical Library Association Hall, Boston, on Monday and Tuesday, June 24 and 25, under the presidency of Dr. V. Y. Bowditch, of Boston.

The following papers are announced to be read:

"Comparative results in ninety cases of Pleurisy, with special reference to the development of Phthisis Pulmonalis." By Dr. V. Y. Bowditch, Boston.

"A Study of the Summer Climate of the Massachusetts Coast." By Dr. William D. Hodges, Boston.

"Reports of Cases of Acute Miliary Tuberculosis." By Dr. John C. Munro, Boston.

"The Mortality of Acute Lobar Pneumonia." By Drs. C. W. Townshend and A. Coolidge, Jr., Boston.

"Consumption as I have known it." By Dr. E. P. Hurd, Newburyport.

"The Influence of Climate and Season upon Normal and Abnormal Manifestations of Nervous Activity." By Dr. Walter Platt, Baltimore.

"The Basis of Rational Climato-therapy." By Dr. Griffith E. Abbott, Bryn Mawr, Pa.

"Ocean Therapy." By Dr. Albert L. Gihon, Surgeon, U. S. N.

"The Vital Statistics of Two Thousand Persons in an Ocean Atmosphere." By Dr. A. N. Bell, New York.

"The Psychological Factor in selecting a Climate for Invalids." By Dr. E. O. Otis, Boston.

"The Wakefulness of Neurasthenia as affected by a Residence at the Seaside." By Dr. W. H. Daly, Pittsburg, Pa.

"The Relations of Sandy Soil and Pine Forests to Pulmonary Phthisis, with special reference to the Pine Belt of New Jersey." By Dr. Isaac H. Platt, Lakewood, N. J.

"Open-air Travel as a Cure and Preventive of Consumption, as illustrated in the History of a New England Family." By Dr. Henry I. Bowditch, Boston.

"Rest and Exercise in Diseases of the Heart." By Dr. A. L. Loomis, New York.

Discussion—"Hemoptysis from Chronic Pulmonary Disease"—

a. Pathology. By Dr. G. M. Garland, Boston.

b. Clinical Significance. By Dr. J. T. Whittaker, Cincinnati.

c. Climatology from standpoints of Etiology and Therapeusis. By Dr. R. G. Curtin, Philadelphia.

d. Other Treatment. By Dr. J. B. Walker, Philadelphia.

"Remarks on the Treatment of Pulmonary Phthisis." By Dr. J. C. Wilson, Philadelphia.

"Some Observations on the Causation and Treatment of Asthma." By Dr. Beverley Robinson, New York.

"The Climatic Treatment of Bronchial Asthma." By Dr. F. I. Knight, Boston.

"Institution for the Treatment of Pulmonary Consumption." By Dr. P. H. Kretzschmar, Brooklyn.

"The Mineral Springs of Colorado." By Dr. Charles Dennison, Colorado.

"The Climate of New Mexico." By Dr. R. M. Longwell, Santa Fé.

"Notes on the Prevalence of Diphtheria at High Altitudes." By Dr. S. H. Chapman, New Haven.

"An Unusual Type of Pulmonary Disease occurring in the Central Mississippi Valley." By Dr. W. C. Glasgow, St. Louis.

Medico-Chirurgical College of Philadelphia.—The following changes have been made in the Faculty:

Frank Woodbury, A.M., M.D., Honorary Professor of Clinical Medicine.

William B. Atkinson, A.M., M.D., Honorary Professor of Sanitary Science and Pædiatrics.

John V. Shoemaker, A.M., M.D., Professor of Materia Medica, Pharmacology, Therapeutics, and Clinical Medicine.

James M. Anders, Ph.D., M.D., Professor of Hygiene and Clinical Diseases of Children.

The New Quarantine Station at the Entrance to Delaware Bay.—It will be remembered that Congress at its last session appropriated a considerable amount of money for the equipment of seven quarantine stations, five for the Atlantic Coast, and two for the Pacific. Of this appropriation, about $75,000 were assigned for the establishment of a thoroughly equipped station for the protection of the Delaware Bay and River. Heretofore the only safeguard against the introduction of contagion below the Lazaretto has been the little hospital of the United States Marine-Hospital Service, near Lewes, simply designed for the treatment of sick or wounded seamen, with no adequate provision for the isolation of those suffering from infectious diseases. So well has this service been administered, however, that it has, on several occasions, detained and disinfected pest-laden vessels and their crews, and thus stayed at the threshold causes which might have resulted in disastrous epidemics had they gained admission. At or near this point the Legislature

of Delaware has offered to cede to the United States the land necessary for the proposed buildings and appurtenances. The Secretary of the State Board of Health of Pennsylvania, Dr. Benjamin Lee, has been designated a Commissioner on the part of the United States to meet Commissioners appointed by the State of Delaware, and in conjunction with them to locate and fix the boundaries of this Reservation. This preliminary will be speedily settled, and work will be begun at an early date. The fumigating steamer for the station is now in process of construction at the Pusey & Jones Company's extensive works at Wilmington, Delaware.

New Appointments in the Berlin Health Office.—Dr. Petri, hitherto Keeper of the Hygienic Museum, has been appointed Chief of the Bacteriological Department in the Imperial Office of Health in Berlin. His successor is Dr. Erwin von Esmarch, son of the distinguished professor and surgeon at Kiel. Both of these men are worthy and successful laborers in the vineyard of which Koch is the chief tiller.—*The Lancet*, May 25, 1889.

Medical Congresses during the Paris Exposition.—Sixty-nine congresses will be held in Paris during the Exhibition. The following are those which will be of special interest to physicians:

Congress for the Study of Questions relative to Alcoholism, from July 29 to July 31.

Congress of Public Assistance, from July 28 to August 4.

Congress of Chemistry, from July 29 to August 3.

Congress of Therapeutics, from August 1 to 5.

Congress of Hygiene and Dermography, from August 4 to 11.

Congress for the Amelioration of the Condition of the Blind, August 5 to 8.

Congress of Dermatology and Syphilography, August 5 to 10.

Congress of Mental Medicine, August 5 to 10.

Congress of Physiological Psychology, August 5 to 10.

Congress of Criminal Anthropology, August 10 to 17.

Congress of Prehistoric Anthropology and Archeology, August 19 to 26.

Congress of Dentistry, September 1 to 7.

Congress of Otology and Laryngology, September 16 to 21.

Congress of Veterinary Medicine, September 19 to 24.

Congress of Hydrology and Climatology, October 3 to 10.

Homœopathists Abroad.—The *British Medical Journal*, in quoting from the most recent official statistics in Austria, shows there are only 118. homœopathists out of the whole number of medical men, 7183, and that only 44 of these profess to practise homœopathy exclusively. There are none at all in the Italian districts, and only 19 in Vienna. The number, also, is said to be steadily decreasing.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 4 TO JUNE 10, 1889.

By direction of the Acting Secretary of War, JAMES C. MERRILL, *Captain and Assistant Surgeon*, is detailed as a member of the Board of Medical Officers appointed by Par. 9, S. O. 108, May 10, 1889, from this office, to meet at the U. S. Military Academy, West Point, New York, on June 1, 1889, or as soon thereafter as necessary, to examine candidates for admission to the Academy, etc., vice Frederick C. Ainsworth, Captain and Assistant Surgeon, hereby relieved as a member of the Board.—Par. 4, *S. O. 127, A. G. O.*, June 3, 1889.

OWEN, W. O., Jr., *Captain and Assistant Surgeon.*—The leave of absence for seven days, granted in Orders No. 18, *c, s*, Fort Gibson, Indian Territory, is extended twenty-three days.—Par. 2, *S. O. 67, Headquarters Department of the Missouri, Fort Leavenworth, Kansas*, May 29, 1889.

By direction of the Secretary of War, the leave of absence granted JEFFERSON R. KEAN, *First Lieutenant and Assistant Surgeon*, in S. O. No. 48, May 13, 1889, Department of the Platte, is extended fifteen days.—Par. 3, *S. O. 129, A. G. O.*, June 5, 1889.

WALES, PHILIP G.—Appointed Assistant Surgeon with rank of First Lieutenant, from June 7, 1889.

DE WITT, THEODORE F.—Appointed Assistant Surgeon, with rank of First Lieutenant, from June 7, 1889.

TEN EYCK, BENJAMIN L.—Appointed Assistant Surgeon, with rank of First Lieutenant, from June 7, 1889.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY, FOR THE WEEK ENDING JUNE 8, 1889.

PAGE, J. J., *Assistant Surgeon* (Retired).—Granted one year's leave of absence, with permission to leave the United States.

BAILEY, THOMAS B.—Appointed an Assistant Surgeon in the Navy, May 23, 1889.

BARBER, GEORGE H.—Appointed an Assistant Surgeon in the Navy, May 23, 1889.

ROTHGANGER, GEORGE.—Appointed an Assistant Surgeon in the Navy, May 24, 1889.

SMITH, GEORGE TUCKER.—Appointed an Assistant Surgeon in the Navy, June 3, 1889.

BAILEY, T. B., *Assistant Surgeon.*—Ordered to the Receiving-ship "Dale," at Washington, D. C.

BARBER, GEORGE H., *Assistant Surgeon.*—Ordered to the Receiving ship "Vermont," at New York.

OGDEN, F. N., *Assistant Surgeon.*—Ordered to examination preliminary to promotion.

BRYANT, P. H., *Assistant Surgeon.*—Detached from the Naval Hospital, Chelsea, and granted a month's leave of absence.

MAYO, H. O., *Medical Director* (Retired).—Granted one year's leave of absence, with permission to leave the United States.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING JUNE 8, 1889.

MEAD, F. W., *Passed Assistant Surgeon.*—Ordered to examination for promotion, May 31, 1889.

CARRINGTON, P. M., *Passed Assistant Surgeon.*—To proceed to Johnstown, Pa., on special duty, June 3, 1889.

MCINTOSH, W. P., *Passed Assistant Surgeon.*—When relieved at New Orleans, La., to proceed to San Francisco, Cal., for temporary duty, May 29, 1889.

SMITH, A. C., *Assistant Surgeon.*—Relieved from duty at Louisville, Ky.; ordered to Marine Hospital, New Orleans, La., May 29, 1889.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked. Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

VOL. LIV. SATURDAY, JUNE 22, 1889. NO. 25.

ORIGINAL LECTURES.

THE THERAPEUTIC VALUE OF ELECTRICITY IN GYNECOLOGY.

A Lecture, delivered by invitation, at the New York Polyclinic, May 21, 1889.

BY AUGUSTIN H. GOELET, M.D.,
OF NEW YORK.

GENTLEMEN: I am here to-day by invitation of our friend, Dr. A. M. Jacobus, to give you the benefit of my experience with electricity in gynecology. Of the three forms of electricity, I will confine my remarks to galvanism. It will, of course, be impossible for me to do more than give you a general outline of the principles involved and the methods of administration; but I will endeavor to make my remarks as practical as possible, in order that you may be able to make use of them in cases arising in your every-day practice.

We recognize in gynecology a distinct active and inactive pole; the active pole being that pole applied to the internal surface of the body, in the vagina, within the uterus, or into the tissues by puncture. It is from this pole that we expect our effect. The inactive pole is that pole applied to the external surface of the body, having for its object only the completion of the circuit. From this we expect no effect, and we get none, if we except the mild counter-irritation produced by the hyperæmia of the surface which occurs under the pad when strong currents are used. You will understand, then, that either the positive or the negative pole of the battery may be the active pole, according to your selection

It is very important for you to understand that the difference in the therapeutic action of the two poles is as great as the difference in their chemical action. You know, of course, that oxygen is generated at the positive pole, and hydrogen at the negative pole; that the positive pole attracts acids from the tissues, while the negative attracts alkalies. In a general way, the positive pole is known as the coagulating pole, while the negative is the liquefying or fluidifying pole. But there is a distinct polar and inter-polar action of the current, the polar action being that action which takes place at the point of contact of the active pole with the tissues, and the inter-polar action being the influence exerted by the current in its passage through the tissues, the greatest action being manifested in proximity to the active pole. These different actions may be more readily appreciated by you, and will be more convenient for you in every way, if they are put in tabular form, and for that reason I have had them written out on the black-board for your future guidance. The positive pole may, then, be divided into its inter-polar and polar action. In its inter-polar action it is *anodyne, sedative, anti-congestive, denutritive, anti-hemorrhagic* or *hæmostatic*, and *alterative*. It acts by contracting the capillaries, will drive out congestion, allay inflammation, and will relieve pain. In its polar or local action it is *styptic* with moderate intensities, and *caustic* and *hæmostatic* with high intensities. As I have said before, it is the coagulating pole, and it is, therefore, useful for arresting hemorrhage when applied intra-uterine. The negative pole in its inter-polar action is *stimulating, congestive, derivative*, and *alterative*, favoring absorption by increasing the blood-supply. In its polar action it is markedly *electrolytic, liquefying*, producing active chemical decomposition, and *caustic* with much lower intensities than the other pole. It is particularly useful in removing obstructions in the cervical canal with moderate intensities, having even with low intensities a decided electrolytic effect.

I have said that the negative pole is the caustic pole. It is, in fact, generally known as the more caustic pole, but it is so only when we refer to the bare or unprotected electrode used within the uterus. I have found that with the protected electrode used in the vagina the positive pole is the more caustic—that is, I have been able to use, in cases which were suitable for it, 200 milliampères with the negative pole in the vagina for five minutes without a caustic effect, whereas, with the positive pole it is impossible to use in the vagina 100 milliampères for the same length of time without producing active cauterization. When a current of that strength is used, I advise that the electrode be dipped in a solution of bicarbonate of soda, which will neutralize the acids that collect at the point of contact and prevent the usual caustic action. The different local actions of the poles may be modified or varied at the will of the operator, by increasing or diminishing the current, or by lengthening or shortening the duration of the application.

You have in electricity, as you will see, an agent capable of exerting a remedial influence over almost every form of disease of the pelvic organs, an agent possessing an infinite capacity for modification, according to the method of its application. In this respect it reminds me of a certain musical instrument, the cornet, which, though it has only three keys, may be made to produce any note at the will of the musician.

An intelligent interpretation of these different actions of the two poles of the battery, forms the basis of electrical treatment, and you must constantly bear them in mind. Experience will, of course, increase your ability for a proper selection of the pole to be used. Take my advice and do not attempt the application of electricity to diseases of the pelvic organs until you have thoroughly mastered the subject—until you are able to apply it with a definite object in view. Make up your mind accurately as to the condition present, and apply the remedy so as to meet the indication. In this way alone can the value of electricity be determined and its future usefulness be advanced, for failure from improper use, by those who do not understand it, is more likely to be attributed to the inefficiency of the agent than to inexperience in

manipulation. *Ignorance is the greatest enemy of progress.* And this especially applies to the use of electricity. If you will take the trouble to investigate the subject, you will find that the opponents of electricity are those who are utterly ignorant of its action and uses. Those who have pretended to investigate the subject with a view of determining its value, have done so under protest, knowing nothing about it, rather desiring its failure than its success, and, failing, they have damned the agent instead of themselves. See that your failures do not produce the same effect.

Now, the position of the electrodes is sometimes of great importance. When you desire the inter-polar influence of the current you must place your internal electrode and your external electrode in such relation to each other that the tissues under consideration or treatment will be immediately included between the two poles; that is to say, if you are treating the diseased condition of one side of the pelvis, place your vaginal electrode at the most accessible place on that side of the vagina, and your external electrode on that side of the abdomen, thus concentrating your current to one side rather than disperse it over the whole surface of the abdomen externally, for by this dispersion you would lose much of the current as well as the effect. In like manner, if it is more convenient to place the external electrode on the lower part of the spine the position must be such that the diseased structures will be included between the two poles. For electricity in passing from one pole to the other to complete the circuit will, as a rule, take the most direct route in spite of the resistance encountered. But when you desire only the local action of the active pole the position of the external electrode is a matter of indifference.

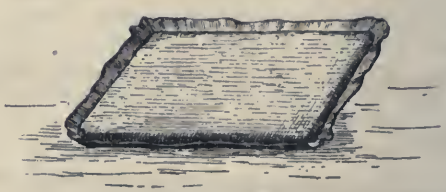
The intensity of the current to be used varies with the condition present and the object to be attained. This, with the duration and frequency of the applications, must be learned by clinical experience. It would be impossible to outline definitely here the intensity of the current and the duration of the application necessary in every case, but in studying each condition I will endeavor to indicate this to you clearly.

As to the meter, this is always a necessity to insure accuracy. Would you think of giving a dangerous drug without knowing accurately the dose you were administering? The meter is necessary not only to insure the safety of the patient, but in order that you may know certainly what you are accomplishing or what you are doing. Do not think that you can work without one, for it is a matter of too much importance. It is necessary, if for no other reason, to show that your battery is working properly, that your conducting cords are all right, and your electrodes in order, and above all, to show that the patient is not deceiving you as to her impressions.

In regard to the form of battery. In my experience the Leclanché apparatus gives the most steady and satisfactory current, but all of you may not be able to possess a cabinet battery of Leclanché cells, and if you select an acid battery, choose one with small elements. The batteries with large elements produce too furious an action—too caustic an action—besides being unpleasant to the patient in the increasing of the current cell by cell. The number of cells may be increased by means of the wince apparatus—that is, the keyboard is fitted with the wince or crank for increasing the current—for the plug and socket arrangement is too inconvenient for the operator and too unpleasant for the patient. Although they may have a double cord to prevent an interruption or break in the current, the patient still feels the increase of each cell more perceptibly than she does from a wince battery.

Of the apparatus for the administration of electricity I will begin by showing you the external electrode. So far as my experience goes the clay pad of Apostoli, with certain modifications, is the best which I have used. The objections that have been made to it, that it is unclean, unwieldy, and uncomfortable to the patient, may be readily overcome by these modifications which I have made. The large size usually recommended for these applications is by no means necessary, except when very high intensities are used, as in the puncture of fibroid tumors. Smaller sizes are more convenient and as readily acceptable to the patient. For instance, the size which I show you, six by eight inches, may be used with

FIG. 1.



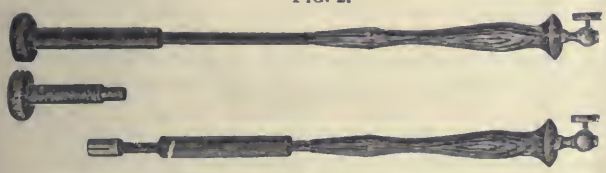
The external clay electrode, showing surface to be applied to the skin.

a hundred milliampères of current without producing any inconvenient or unpleasant action upon the skin, and even smaller sizes than this may be used for smaller currents. This is made of ordinary potter's or moulder's clay rolled out with a rolling-pin upon a flat surface after having been first mixed to the consistence of putty. It must be perfectly smooth and of a uniform thickness. In an electrode of this size it may be three-quarters of an inch thick. It is then cut into the desired size and shape and a metallic plate with binding-post attached pressed into the back of the pad—merely pressed into the clay, not imbedded. It is covered with a layer of absorbent cotton, taking care to have the binding-post penetrating this and the other layers. It is then sewed up in linen crash, the seam always being on the back of the electrode, so that the surface to be applied to the skin may have no unevenness and be perfectly smooth. Afterward it is backed with rubber cloth, which prevents wetting the clothing of the patient. The absorbent cotton, beside serving to keep the clay moist when not in use, forms a protection which prevents the clay from oozing through and soiling the surface to which it is applied. This may be kept warm in an ordinary pan over a small oil lamp and the unpleasantness of the ordinary cold clay pad avoided. For the sake of convenience I prefer in some of the pads to have the connecting post at the end, which allows it to be slipped up under the clothing and avoids the necessity of loosening the clothes. In applying electricity with a view to its inter-polar action it is often desirable that the size of the external electrode should be limited as much as possible, or as much as the sensation of the patient will allow without inconvenience, in order to concentrate its action.

The ordinary vaginal electrode I do not use at all, because it cannot be protected so as to prevent a caustic

action upon the mucous surface. This is on account of the size of the ball and the metal of which it is made. I use with the negative pole a flat metallic disk, a little smaller than the ordinary penny, and this I cover with potters' clay moulded round it. Then I cover it with a very thin layer of absorbent cotton, which, in its turn, is covered by absorbent gauze held in position with a rubber band round the shaft of the electrode. This is used with the negative pole only and is easily kept moist. I have been able to use with the negative pole from fifty to two hundred milliampères through the vagina with this electrode. It would not do to use this electrode with the positive pole because of the metal, which would be corroded by the acids after a few applications, perhaps after the first. I therefore use with the positive pole an electrode with a disk made of carbon, which is not affected by acids. But the connection with the metallic rod of the handle must be removed sufficiently far away from the disk to prevent corrosive action at the point of contact with the carbon, which would interfere eventually with the passage of the current. In

FIG. 2.



The carbon-tipped vaginal electrode.

this electrode the connection is at least an inch and a half or two inches away from the disk. The carbon tip consists of a disk with a spindle at least two inches in length. This I cover in the same way with potters' clay, absorbent cotton, and gauze, and it may then be used either with the positive or the negative pole. At the same time, however, it is intended more particularly for the positive pole. When it is to be used, an additional covering of absorbent cotton is placed upon it and moistened. After it has been used once this outer layer of cotton is removed and replaced by a fresh piece for the next application. But the carbon is such a good conductor of the current that you are apt to get more caustic action than you would from a metallic electrode of poorer conducting quality, and for this reason, with currents of more than fifty milliampères, I dip the electrode in a solution of bicarbonate of soda previous to its being used.

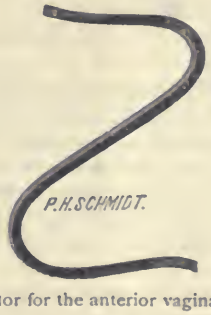
You will readily see that it would be very unpleasant to the patient to have introduced an electrode of this size into the vagina along the finger as a guide unless there was considerable relaxation of the vulva. It therefore became necessary for me to devise some instrument to facilitate the introduction of the electrode. Besides the inconvenience and unpleasantness to the patient of passing the electrode along the finger, the hand of the operator is soiled, and it becomes necessary for him to delay long enough to cleanse the hand if it is needed for turning on the current. The facility of introduction of intra-uterine electrodes is much enhanced by exposing the cervix to view, and is to be preferred to the method of introduction along the finger as a guide, both because it allows more delicate manipulation, and because it is safer for the patient. To overcome these difficulties I have devised the instrument which I show you. It is a modification of the Sims speculum. Of course, when your patients may be placed in the lateral position for applications, the Sims instrument would answer, but when the applications are to be made in the dorsal position the Sims speculum would be unsuitable, and the ordinary bivalve instruments in use do not permit sufficient expansion at the vulva to allow the introduction of this electrode without considerable inconvenience to the patient.

FIG. 3.

The speculum.

This instrument, as you see, consists of two Sims blades joined together by a very short shank and in opposite directions, forming the shape of the letter S. It may be used in either the dorsal or the lateral positions. When used in the lateral position in place of the Sims instrument, it is more readily held by the nurse as well as by the physician. It is more convenient for the physician if he is using it without a nurse than the Sims instrument. It is self-retaining without the support of the hand. In the dorsal position it may be used likewise without a nurse or without any assistance from a depressor unless there is unusual relaxation of the anterior vaginal wall, and, when this interferes with a view of the cervix, I use what I call an elevator of the anterior vaginal wall. It is made of hard rubber and

FIG. 4.



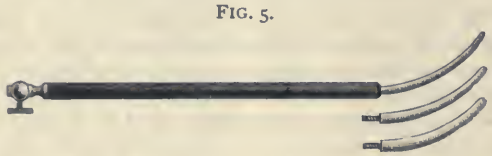
Elevator for the anterior vaginal wall.

curved in an S shape, so that it may fit over the pubis and be held with one finger of the nurse. If the physician is operating without the assistance of a nurse, all that is necessary for him to do is to ask the patient to hook her little finger into the upper curve of this elevator, and she can render him, with little or no inconvenience, all the assistance he requires. When used in

the dorsal position, the speculum is held by the physician in the left hand and the retraction of the perineum is done by him. In order to get this left hand out of the way I usually pass it between the right foot and buttock of the patient, and in that way hold the speculum. In my every-day practice I have come to rely upon this instrument, and use it in preference to the Sims. The advantages of a speculum of this construction are so numerous that, although I have always four or five of the Sims instruments on my table, I continually find myself turning to this for any work that I have in hand. It is now made of hard rubber as well as metal, to avoid the necessity of withdrawing it during the application.

For use with the negative pole almost any metal will be suitable for the electrode if the surface is kept clean and bright. Usually they are made of brass or copper, nickel plated. For use with the negative pole for applications to the cervical and uterine canal, I have devised an instrument which I prefer to the ordinary bulb electrode in general use for this position. It consists of three metal tips, their sizes being 13, 15, and 17 of the French scale. The tips are nearly two and a half inches long, of the usual curve, and are conical at the point. They screw into an insulated handle at a decided shoulder. I consider this shoulder very important, as, when we have penetrated the distance of this shoulder, we are certain that we have gone through the internal os and

FIG. 5.



Electrode for the application of negative galvanism to the cervical canal.

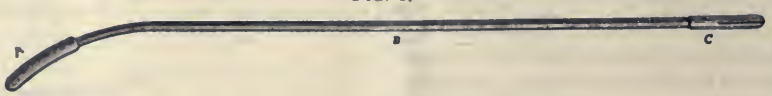
we need go no further. In this way we avoid the contact of the tip with the fundus of the uterus. I prefer this, I have said, to the ordinary bulb electrode because it is more easy of introduction and because the current is distributed over a greater surface and you do not get such intensified action at one spot. This is used with the negative pole for flexions and obstructions in the cervical canal. In applications of negative galvanism to the endometrium smaller tips may sometimes be necessary, but ordinarily the smallest sized tip answers every purpose.

In operating with the positive pole we must have a metal or substance which is not acted upon by acids, and platinum and carbon are the only substances heretofore used for this pole. Aluminum may be left out of the question, as it is too easily acted upon by high intensities with the positive pole. Platinum is very expensive, and carbon is absorbent, and for this reason cannot be rendered thoroughly aseptic. Beside, the carbon electrode must necessarily be straight. I have used for the past six months electrodes made of wrought iron and steel protected by a process of treatment which renders the metal absolutely non-corrosive and non-attackable by acids for a considerable length of time.

I show you here the tip (two and a half inches long) which I use, and have been using since January, and there is, as you see, very little action commencing upon the metal. Electrodes made of this material and treated by this process are so inexpensive that they may be thrown away when there is the slightest sign of corrosion upon them, but they will resist for a long time, and, besides, it is a better conductor of the current than platinum. This electrode, with a tip two and a half inches long, is intended for applications of positive galvanism to the entire uterine canal at once.

When it is desired to make the application only to the cavity of the uterus, it is necessary to have an electrode shorter than this, and for this purpose I have had an electrode made of the same material, three-quarters of an inch in length, which may be screwed into an insulated handle which is curved. This is fashioned after the Apostoli carbon electrode, and, besides the advantage of cleanliness, it is curved, and for that reason may be more easily introduced into the canal. It would be quite impossible to introduce the straight Apostoli carbon electrode into the canal in some cases, and very inconvenient to introduce it in all cases. It is more natural to have an instrument which is of the proper curve, and this can only be done by having a metallic tip upon a curved shaft. This tip should be of different sizes, 12 to 16 French, and the size should be selected with a view to the size of the uterine cavity. A tip should be used which would fit into the uterine cavity so as to be in contact with the whole surface to which it is applied; that is, it should not fit loosely into the uterus. For this reason different sizes are necessary. The tips are made three-quarters of an inch in length, so that the uterine cavity, exclusive of the cervical canal, may be cauterized in two sections. Passing it up to the fundus, it is left there long enough to produce the action you desire, and then it is withdrawn the length of the tip that is marked upon the shaft of the electrode, and the second section is cauterized. When the whole cavity is thus cauterized it may be removed without producing any effect upon the canal of the cervix. This is usually the most sensitive part of the whole canal, and will not tolerate the intensities which may be applied to the cavity, besides, atresia might follow.

FIG. 6.



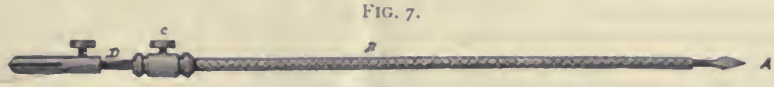
Electrode for applications of galvanism to the uterine cavity.

I show you here also an ordinary puncturing needle, which is screwed into an insulated shaft or handle. But this is an instrument which I should not advise to be used except by experienced hands—I mean experience in application—for, as you will see, it has no shield or guide to limit the penetration. I would advise beginners (and prefer even myself in many instances) to use a needle with a sliding protection upon the shaft fixed by a screw so that a limit to the amount of penetration

may be made. In this way you need not go through the tumor, but stop when you have penetrated it a certain distance, an accident which might occur if you used a needle without this protection.

I show you here an aspirating trocar and canula. This, has a protecting sliding covering of catheter material and a screw adjustment to limit the amount of penetration, and is used for tapping small cysts and hydrosalpinx, and pyosalpinx when accessible through the vagina. I would not have you infer, however, that I advise its use in all cases. It is, in fact, only applicable in certain conditions. I tap the sac with this trocar and canula, withdraw the trocar, and empty it of the fluid.

FIG. 7.



Puncture needle with sliding cover to limit penetration.

The trocar is then reintroduced and the attachment made with the battery, with either pole (usually the negative pole is preferred), with the current turned on (from fifty to one hundred milliampères) thus cauterizing the tissues which are penetrated by the canula, and in this way avoiding the chance of the absorption of any septic material. Beside, the action of the current upon the collapsed sac tends to prevent the reaccumulation of the fluid. I seldom find it necessary to tap the sac more than once. While it may be advisable to do this in most cases of hydrosalpinx where easily accessible, it is not always wise to do it for pyosalpinx. I prefer to drain a pyosalpinx through the uterus. Frequently I have been able to accomplish this by applications of strong positive galvanism to the entrance of the tube into the uterus (into the cornua of the uterine cavity on that side), by means of a small platinum-tipped electrode the size of an ordinary uterine sound and not more than a half to three-quarters of an inch in length. In several instances I have been able to drain the pyosalpinx in this way through the uterus intentionally. I first discovered this accidentally after applying a current of a hundred milliampères to the cornua on the diseased side; the withdrawal of the electrode was followed by the escape of a tablespoonful of pus, and the patient experienced immediate and permanent relief. Several times since this accidental discovery I have accomplished the same thing, but I cannot say definitely that it can always be accomplished. When this cannot be accomplished and when the condition is appropriate for it the tube may be tapped through the vagina.

When a pyosalpinx is tapped by the vagina it is best always to wash the cavity of the tube thoroughly through the canula with an antiseptic solution, generally either with an aspirator or with the surgical pump, before the galvanism is applied to the track of the canal. Permanent drainage may be secured through this cauterized drainage track and the cauterization prevents the absorption of septic material in its passage along this opening. The opening remains patulous for several days, usually as long as there is any necessity for drainage. If closure occurs it is an easy matter to pass the trocar again, or a small blunt electrode along the track while connected with the negative pole of the battery. It will work its way along the track made previously and enter the sac, reopening it for drainage.

FIG. 8.

Aspirating trocar and canula.

The diseases which I have found amenable to treatment by galvanism and which have yielded very satisfactorily to the treatment, I may say often more satisfactorily than to any other form of treatment known to me or heretofore used by me, are: Uterine flexions, obstructions in the canal, hypertrophy of the organ, metritis, endometritis, menorrhagia and metrorrhagia, chronic pelvic cellulitis, exudations and adhesions, hæmatoma and hæmatocele, ovaritis and salpingitis, and certain conditions of hydrosalpinx and pyosalpinx.

I have not yet quite made up my mind that electricity is proper for actual stenosis. I prefer to dilate first and maintain the dilatation in the beginning with the intrauterine stem worn for one week only while the patient is confined to bed, and subsequently by the use of negative galvanism to the canal. In treating flexions and obstructions in the canal we use negative galvanism as a rule, and the strength necessary will vary from ten to fifty milliampères, according to the condition and chronicity of the case. Cases of chronic hypertrophy are likewise treated by negative galvanism. Chronic metritis and endometritis are usually treated with positive galvanism, but there are conditions which call for treatment by the opposite pole. Menorrhagia and metrorrhagia may be treated by positive galvanism with currents varying from fifty to one hundred milliampères used intrauterine. Chronic pelvic cellulitis, exudations and adhesions of long standing, after all inflammatory action has subsided, yield readily to treatment by negative galvanism by the vagina, and it is in these conditions that I maintain strong currents are required. I frequently reach two hundred milliampères in the treatment of these conditions and find that exudations and adhesions melt away like ice under the rays of the sun. Of course, it would not do to begin the treatment of a case by using such high intensities. Beginning with fifty milliampères, treating the case every second or third day, and gradually increasing the dose, the tolerance of the current may be increased, and the high intensities, when reached, will produce no more discomfort or inconvenience to the patient than the small dose did at the beginning. As the menstrual period approaches if there is a tendency to over-menstruation the intensity must be lowered, and in beginning the treatment again after menstruation a smaller dose must be applied and again gradually increased. Fixation of the pelvic contents is to be treated in the same manner. A good rule to follow is to use positive galvanism in the vagina for its inter-polar action as long as there is any active inflammation, or as long as the vaginal roof is

sensitive to ordinary pressure. When the condition is chronic, or when the roof is sensitive only to deep and sudden pressure, negative galvanism is indicated.

Hæmatoma and hæmatocele afford a striking illustration of the prompt remedial influence of electricity. Hemorrhage, in a case seen early, may be controlled to a certainty by positive galvanism applied through the vagina. When the case is seen after hemorrhage has ceased, positive galvanism is indicated to control further hemorrhage, to contract the clot which has formed, and to hasten the separation of the serum. If the separated serum is of considerable quantity and produces pain from pressure, it may be withdrawn by trocar and canula in the same way that I described the withdrawal of the hydrosalpinx, but positive galvanism must be used immediately afterward to contract the capillaries and prevent the recurrence of hemorrhage and to favor the closure of the sac which contains the fluid. Positive galvanism must be used, however, for some time subsequently to produce a still further contraction of the clot, and as soon as all sensitiveness has subsided, and all inflammatory action surrounding the effusion has been subdued, negative galvanism may be applied through the vagina to hasten absorption, or, if the case is an obstinate one, absorption may be hastened by negative galvano-puncture of fifty to one hundred milliampères.

Small cysts and fibro-cysts of the ovary and in the broad ligament frequently yield readily to negative galvano-puncture through the vagina, some of them requiring only one puncture for their complete removal.

Fibroid tumors of the uterus are reduced in size by applications of strong currents by galvano-puncture. The growth of the tumor is arrested, it is lessened very materially in size, and frequently is reduced so much as to give no further inconvenience to the patient. I have been thoroughly satisfied so far with my experiments with electricity in the treatment of fibroid tumors. Very large and hard tumors of long standing yield slowly and demand strong currents, frequently from two hundred and fifty to five hundred milliampères, and, of course, necessitating the use of an anæsthetic. In many of the cases I have been able to puncture at my office and send the patient home in the carriage. I should not care to advise it in all cases. I prefer to put the patient to bed immediately after the operation and keep her there until all unpleasant symptoms have subsided. Where hemorrhage occurs from the uterine cavity in connection with these fibroids, we treat them by positive galvanism to the endometrium, as advised by Apostoli, administering one hundred to one hundred and fifty milliampères, cauterizing the whole uterine cavity.

THE SURGICAL TREATMENT OF THE TONSILS AND ALLIED BODIES WHEN A CAUSE OF PHARYNGEAL IRRITATION.

BY HARRISON ALLEN, M.D.,
OF PHILADELPHIA.

ON a former occasion[1] I invited attention to the subject of pharyngeal irritation which appeared to be excited and maintained by small tonsils, and by the glands below the tonsils on the side of the pharynx. My studies in this direction, since the date of the paper named, have tended to confirm the importance of the conclusions therein stated, and I venture to submit the following detailed account of the manipulations which, in my hands, have proved to be of value.

THE TONSILS.—When the symptoms of pharyngeal inflammation do not subside by the use of gargles and sprays, or after internal medication, it is probable that a local cause exists which will yield to surgical means only. In order to determine the exact condition of the tonsil, the following method of examination is recommended. A tongue depressor is placed upon the tongue and given to the patient to hold. The mouth is opened to its widest extent, and an aneurism needle (the adjustable end of which has been firmly soldered on to the shank or handle) inserted behind the palato-glossal fold, and gentle traction made forward and slightly outward. To a patient who is untrained it is quite likely that gagging will ensue upon this manipulation. With the exercise of a little care, however, the irritability may be so far overcome as to enable the tonsil to be freely seen. Very often no trace of a tonsil is discerned until such a manipulation is resorted to. Tonsils which are concealed between the palato-glossal and the palato-pharyngeal folds of the pharynx are very apt to give rise to irritation. Their condition can be determined in no other way known to the writer, than the one indicated. It is an interesting fact that the act of gagging itself rather assists than otherwise in the examination, since a disposition exists for the tonsil to be turned slightly upon itself. If the patient remains composed and does not move the shoulders backward, both he and the physician can remain indifferent to the gagging as long as it does not excite vomiting.

The tonsil is ordinarily composed of two masses, an upper and a lower. They might be compared to two beans lying within a pod ; the two portions lying in such wise that the lower is in advance of the upper. The spaces between them are often found occupied by pellets of solid secretion, which, owing to the unfavorable position of the folds, have been unable to escape into the throat. Such masses are persistent causes of irritation, and may themselves be the main cause of pharyngitis and laryngitis. They are, in most instances, easily removed by a scoop held in the left hand, while the right is engaged in drawing forward, with the retractor, the anterior fold. The pellets lying between the tonsil-masses may be embedded in their substance or be lodged in pockets. Such is especially the case with the upper tonsil-mass, which may lie far up in the tonsillar space and be adherent by all its surfaces, except the median, to the surrounding membranes.

[1] The Tonsils and Pharyngeal Irritation, THE MEDICAL NEWS, July 8, 1882, p. 31.

Secretion so retained is best removed by the galvanic cautery, an electrode being used which retains a very small platinum loop projecting from the end of the insulated shaft.

I have notes of three cases in which the upper tonsil-mass was the seat of a small abscess which gave rise to extreme distress of the pharnyx, and induced laryngitis which persisted for some months after the tonsillar condition was entirely corrected.

The lower tonsil-mass may be adherent by synechial bands to the palatal folds. The union to the anterior fold is not, as a rule, accompanied by distress, but that with the posterior fold it is invariably the source of great irritation, which in my judgment remains unrelieved until complete division of the united surfaces is effected. The same remark is true when the posterior surface of the lower mass is adherent to the outer wall of the pharynx.

Not infrequently, the lower mass is retroverted; that is to say, it is turned back on itself in such a manner that the surface which should point toward the lumen of the pharynx is directed outward, and is in contact either with the posterior fold or the lateral wall of the pharynx. In these conditions it is inevitable that each movement of the palato-pharyngeal muscles teases the entire pharynx. To correct the evils of the false union, above named, all bands and surfaces of adhesions must be freely divided, and the cut surfaces seared so as to prevent the reëstablishment of their union. When the pharynx is excessively irritable a species of trismus appears to be excited, which often makes it difficult to open the mouth for a distance sufficient for the easy manipulation of instruments. In many individuals, this disposition is almost impossible to overcome. Another difficulty is recognized in the gagging which ensues in the use of the knife or electrode. Especially is this the case when the tonsil is to any degree retroverted.

The instruments which are needed for the separation of the bands of false union are few and simple. The manipulation attending their use is much the same as in the removal of retained tonsil secretion. The tongue being depressed by the patient, and the mouth held open as wide as possible, the retractor is made to expose the lower tonsil-mass with the right hand, while the left hand carries a pair of Tieman's bullet forceps to the tonsil, and a portion of the gland is firmly seized. The right hand now relinquishes the retractor, and the tonsil being drawn out into the throat as far as is practicable, a bistoury is taken by the disengaged right hand and employed to separate the surfaces in any desired direction. In some cases a tenaculum can be substituted for the bullet forceps, but in order for it to prove effective the shank, which bears the hook, must be turned at a right angle for a distance equalling the length of the hook itself. This enables the operator to insert the tenaculum within the tonsil-mass by simply rotating the instrument within his hand. The instrument is precisely similar in plan to the perforated needle used by J. Marion Sims. The employment of the galvano-cautery is often made compulsory when the irritability of the parts or the intractableness of the patient is very great. The electrodes should be of small size and inserted in the recesses or pockets of the tonsils, small portions only being destroyed at a time.

THE INFRA-TONSILLAR GLANDS.—These bodies, which are glandular in character and which lie on the sides of the pharynx below the tonsil, are often enlarged and serve as sources of irritation when the tonsil itself is healthy. From the proximity of the more inferiorally placed bodies to the epiglottis, the infra-tonsillar glands may be an exciting cause to laryngeal cough. These bodies are conveniently named the infra-tonsillar glands. Resisting as they do all attempts to reduce their size by medication, it often becomes necessary to destroy them. This is best done by the galvano-cautery. Surfaces ranging in size from one to four millimetres may lie in clusters or groups between the lower margin of the tonsil and the epiglottico-pharyngeal fold. One or two of the bodies can be safely destroyed at a sitting. As a rule, the parts can be exposed by depressing the tongue, but, if in exceptional cases this is not practicable, the tongue may be held by the patient in a position for laryngoscopy, and the electrode applied to the gland.

A CASE OF CHOLELITHOTOMY, WITH REMARKS UPON THE SURGICAL TREATMENT OF CHOLELITHIASIS.[1]

BY MILES F. PORTER, M.D.,
OF FORT WAYNE, IND.

MRS. J. L. P., æt. fifty-two years, mother of four children, of English birth, but a resident of this country for more than forty years, and of Arkansas for the past three years, consulted me the latter part of January last. She passed the menopause normally four years ago. In the past two years she has lost sixty pounds in weight, though, aside from a few chills of ague and a very tired feeling in the morning, she has not been sick.

She suffered at times from "wind in the stomach," but not to give rise to more than discomfort. About three weeks prior to her visit to me she had one of these attacks, and to relieve it she was rubbing her stomach, as was her custom, when she discovered a tumor, for which she consulted me.

A careful inquiry failed to elicit from her any further history than that given, and nothing of importance in her family history; but her sister stated to me that she (the patient) had frequently suffered, in years gone by, with very severe pain in the belly, and that she was often jaundiced, while I remember,

[1] Read before the Indiana State Medical Society, May 2, 1889.

myself, having given her, two years ago, a hypodermatic of morphia for a pain in the belly, but, as there was another case in the house at the time interesting me very greatly, I accepted her diagnosis of "wind colic." Whether or not she was jaundiced after that attack, I do not know.

The following notes are taken from my record book: Complexion rather muddy, bowels constipated, flesh flabby, abdominal walls lax but rather fat. There is in the right hypochondriac region an apparently solid tumor, about size of fist, which moves with the liver in respiration, which can be moved latterly and upward to the right, but cannot be made to cross to the left of the *linea alba*, neither can it be moved downward much. The lower border of the growth can be grasped with the hand, but am not able to separate it from the liver. The percussion note over the tumor is dull. Handling gives distress in the left hypochondriac region and epigastrium, but no pain. The ascending colon is to the outer side of the tumor. She has an anal fistula, which has existed for seven years, at times closing, only to open again, and piles which date back two years.

My diagnosis is a solid tumor connected with the liver, and probably the gall-bladder filled with calculi. I explained to the patient my diagnosis, together with the uncertainties connected with the diagnosis of such cases without opening the abdomen. She was very loath to return to Arkansas, where she would be miles away from a competent surgeon, without at least knowing the exact nature of her trouble, and, on being told by me that the mortality-rate of exploratory operations was not over two per cent., she decided to have it done, and said that "she knew there was something in there which had no business there," and that she wanted it removed if I concluded, after opening the belly, that the chances of life and death would be even.

The operation was accordingly made on the 10th of February, in a private house, in a room especially prepared, and with the assistance of Dr. H. McCullough, Dr. T. J. Dills giving the ether. The incision, three inches long, was made over the most prominent part of the tumor and parallel with the *linea alba*. The tumor being exposed, a small trocar and canula was inserted into it, and, on removing the trocar, a small quantity of muco-pus escaped, but no stones were felt, and the canula was therefore withdrawn and the trocar alone inserted, which immediately came in contact with the stones. Two strong silk threads were now inserted in the most prominent part of the tumor, parallel with each other and about half an inch apart, by which it was drawn well up to the abdominal walls and held there by Dr. McCullough while the incision was made between the threads and the stones removed—ten in number and about the size of chestnuts. The peritoneum was protected by sponges. The gall-bladder was much thickened, measuring about $\frac{3}{16}$ of an inch. The stones were extracted with a pair of uterine dressing forceps, aided by the finger and a blunt aneurism needle. The latter was found to serve an excellent purpose in dislodging the last stone, which was firmly impacted in the neck of the bladder, and I should not want to commence another like operation without this or a similar instrument at hand.

Not being positive that the peritoneum had entirely escaped contamination, two glass drain tubes were placed, one at the side of the gall-bladder from which some adhesions had been torn, and one which reached lower in the general peritoneal cavity. A small rubber tube was placed in the gall-bladder, the latter stitched to the abdominal walls, and the rest of the incision closed with interrupted sutures of iron-dyed silk. She was under ether about two hours. Shock was slight. The glass tubes were cleansed every two hours by suction, and removed at the end of twenty-four hours, as they were doing no good. There was considerable nausea and vomiting from the ether, but this stopped within the first twenty-four hours.

The recovery was uninterrupted save by vomiting, which occurred once on the twelfth day, and was due to eating heartily of farina pudding with raisins in it. No pain of consequence was complained of. With the exception of two seidlitz powders, no medicine was given. Uneasiness from gas was relieved by the daily use of enemas and the use of the rectum tube. After the first twenty-four hours the bile flowed through the tube abundantly, though there was at no time any leakage of bile of consequence around the tube, notwithstanding the rather long incision it was necessary to make in order to remove the calculi. The patient slept well from the first. A superficial stitch was removed on the fourth day, one of the deep parietal ones on the fifth, and, as supposed, all of them on the seventh day, though two more were found and removed on the tenth day.

The dressings were of carbolized gauze and absorbent cotton, and were changed three or four times daily with a view to keeping the wound dry should leakage of bile occur.[1] There was no pus formation, and all of the wound, except that represented by the gall-bladder, healed by first intention. By the end of seventeen days the wound was healed up to the tube, and it was removed. The discharge of bile gradually grew less, and the fistula closed on the thirty-seventh day and remained closed for ten days, when it opened during an attack of vomiting from acute indigestion, and remained open for two days, since which time it has remained closed.

The highest temperature was 101⅘° F., and the highest pulse-rate 90, both of which occurred on the twentieth day, and were due to temporary closure of the anal fistula, which opened the next morning, when both pulse and temperature dropped to normal.

On April 4, I operated for the anal fistula, from which operation she has now (April 9) practically recovered.[2]

Were I to operate again for gall-stones I should use the continuous suture by Tait's method for se-

[1] The tube draining the gall-bladder was left long and emptied the bile outside the dressings.

[2] It is well to add that I was consulted yesterday, May 27th, by the patient when I found that a hernia had developed at site of operation. It causes slight inconvenience and is easily reduced and retained.

curing the gall-bladder to the abdomen, inasmuch as the interrupted sutures are quite difficult to remove, especially if the patient is fleshy.

In THE MEDICAL NEWS of February 9, 1889, is copied an abstract of an article by Dr. A. De Page upon "Surgical Intervention in Biliary Lithiasis" (*Journ. de Med. Bruxelles*, 1888, No. 24), from which we learn that up to date there had been 78 cholecystotomies made:

"Of these operations, 6 were done according to the method of Spencer Wells, 72 with suture of the gall-bladder to the abdominal wall. Of the first-named series 3 died of acute peritonitis, 1 cured case was followed by recurrence, and 2 cases were completely cured. Of the second series there were 11 deaths—5 from hemorrhage and collapse, 2 from biliary retention, 2 from effusion of bile into the peritoneum, and 2 from undetermined cause; there were also 4 deaths from secondary complications. Amongst the 'cures' are 24 cases of biliary fistula, some permanent. The number of cholecystectomies has been 22, with 2 deaths from obstruction of the bile-duct, and 1 after recovery from the operation from a cause independent of biliary lithiasis. Thus, in cholecystotomy with suture of the gall-bladder and its return free into the abdominal cavity, a mortality of 50 per cent. resulted; in cholecystotomy with suture of the bladder to the parietes, 15.27 per cent.; and in cholecystectomy, 9.99 per cent.; and as the last-named figure comprises the two cases of permanent occlusion of the common duct, the result, if they be excluded, is to enhance greatly the position of cholecystectomy as an operation to be preferred to cholecystotomy."

Notwithstanding the lower death-rate in cholecystectomy, it seems to me that cholecystotomy, with suture of the gall-bladder to the parietes, is the operation to be preferred in these cases, for we can never be absolutely certain that the bile-duct is patent;[1] and should calculi reform after this operation, or should it for any reason become necessary to reopen the gall-bladder, the operation (with this viscus attached to the parietes) becomes a trivial one.

While the danger of permanent fistula after this operation is used as an argument against it, yet it seems to me that it should weigh in the other direction; for a fistula remaining, in spite of efforts to close it, is proof of partial or complete closure of the duct, and, where this condition obtains, the patient's life depends upon this outlet for the bile remaining open.

Aside from other objections, it seems that the mortality attending cholecystotomy by Wells's method is sufficient reason for its abandonment.

No. 100 FAIRFIELD AVENUE.

MEDICAL PROGRESS.

Dry Antisepsis.—Since the early days of its introduction, antisepsis has undergone great changes. The principles are the same, but the methods of procedure have been greatly simplified, and their adoption rendered more general. Some recent investigations in connection with irrigation have afforded important results. In many cases, flushing of the abdomen in laparotomy has been found to lower the temperature and increase the risks of shock. To obviate these risks, DR. LANDERER, of Leipzig (*Wiener med. Presse*, No. 19, 1889), has conceived the "dry method" of operating, which he claims has been attended with most successful results, and it is warmly advocated by a number of German surgeons. His aim is to obtain antiseptic results without resorting to the use of antiseptic solutions, and his method of conducting operations, briefly stated, is as follows: The instruments, having previously been boiled, should be kept in a solution of carbolic acid during the operation. The hands of the operator must be antiseptically cleansed. During the operation the blood should be sponged away by means of dry bichloride gauze, and those parts of the wound where the operator's knife is not at work should be kept packed with tampons of sublimate gauze. At the close of the operation, after the larger vessels have been ligatured, the wound should be thoroughly dried with the sublimate gauze, and then closed. No drainage is necessary, for, according to Landerer's experiences, when this dry method has been used, no secretions are formed in the wound. The wound should then be dressed with dry antiseptic or sterilized dressings, and a bandage with moderate pressure applied. In ninety operations performed by Landerer, in which his method was employed, all the wounds healed by first intention.

The principal points gained by dry antisepsis are as follows: First, the avoidance of the frequently fatal chilling and wetting of the patients; secondly, decided decrease in the amount of blood lost, which, thirdly, greatly facilitates rapid operating; fourthly, sure and speedy healing. Also, as the quantity of antiseptics used is reduced to a minimum, dangers from poisoning due to the absorption of the drugs employed are almost entirely avoided.

The simplicity of dry antisepsis renders it equally adaptable to the practice of the country or army surgeon as well as to that of the city or hospital practitioner.

The Treatment of Leucorrhœa.—The following prescription has been found most efficacious, by DR. MONIN, in stubborn cases of leucorrhœa:

℞.—Infusion of chamomile . . ℥xvij.
Alum . . . . . ℥ijss.
Iodide of potassium . . . ℥j.
Tincture of iodine . . . ♏xxxij.—M.

Three injections should be made daily, and, in addition, general tonics and sulphur baths are advisable.—*Gazette de Gyn.*, May 1, 1889.

The Surgical Treatment of Tubercular Peritonitis.—In a noteworthy article by DR. F. SPÄTH, of Hamburg, in the *Deutsche medicinische Wochenschrift* of May 16, 1889, on the surgical treatment of tubercular peritonitis, the following conclusions are reached:

1. In cases of primary tubercular peritonitis in which no other organs are involved, laparotomy can be looked upon as a curative measure, and recommended.

2. In cases of tubercular peritonitis in which the tuberculous process has involved the female genitals, no defi-

[1] Vide Abdominal Surgery, by Greig Smith, 2d ed., p. 593.

nite results have been obtained, whether the diseased portions of the genital organs were extirpated or not.

3. In cases of tubercular peritonitis orginating from tubercular growths of the bowels, the operative treatment is only valuable as a palliative.

4. In cases of tuberculosis of the genital organs, unaccompanied by peritoneal tuberculosis, speedy and early operative interference is of value. The indications for such a procedure are very obscure, owing to the difficulty of obtaining a bacteriological diagnosis.

5. Primary tubercular peritonitis is a much rarer disease than has been heretofore considered; therefore, a positive diagnosis should only be accepted when based upon careful bacteriological investigations.

Constipation in Females.—DR. LUTAUD gives the following formula, which he has found most efficacious in stubborn constipation in females:

℞.—Citrate of iron and ammonium .	31 grains.
Fluid extract of cascara sagrada .	32 ♏.
Saccharine	8 grains.
Distilled water	f ℥ijss.—M.

Half teaspoonful before each meal.—*Revue de Thér. méd.-chir.*, May 1, 1889.

Abortion Produced by Tampons of Iodoform.—In two cases of necessary abortion during the third month of pregnancy, DR. SSOLOWJEN resorted to the following method of treatment. Small balls or tampons of iodoform cotton were pushed into the cervix and held in place by a vaginal tampon. As soon as a tampon was expelled into the vagina it was replaced by another. The third ball of iodoform cotton was pushed into the uterus and after its expulsion fourteen tampons were inserted, whereupon the fœtus was expelled. The first patient had a high temperature during the abortion but was well immediately after. The second patient, in whom the manipulation had to be continued for three and one-half days, also had fever for one day. Ssolowjen considers the use of iodoform tampons a most valuable agent for producing abortion.—*Centralblatt für Gynäkologie*, May 4, 1889.

The Antiseptic Treatment of Diphtheria with Quinoline.—DR. DORNAT, in the *Gazette hebdomadaire Méd. et de Chir.*, April 19, 1889, recommends the use of quinoline as a local remedy in diphtheria on account of its antiseptic properties, and says that he has found it most efficacious.

As a gargle, he prescribes it in the following formula:

Quinoline	grs. 9.
Alcohol (at 194°)	f ℥j.
Boiling distilled water . . .	f ℥xvj.
Essence of menthol	gtt. j.

For local application:

Quinoline.	grs. 15.
Alcohol (194°))	
Distilled water)	āā f ℥vij.

Creolin in Flatulency.—DR. HILLER, in the *Deutsche med. Wochenschrift*, April 25, 1889, recommends the use of creolin in cases of flatulency. He has found that doses of five to fifteen grains, given in gelatine capsules, three times a day, are most effectual. No unpleasant symptoms were observed to follow its use even when given in two-drachm doses. Dr. Hiller advises, however, that the treatment should begin with doses not greater than from two to five grains.

Treatment of Suppurating Buboes with Iodoform.—Although the treatment of suppurating buboes with iodoform is not new, the manner of applying it, as told by DR. FONTAN, in the *Lyon Medical*, April 26, 1889, is certainly novel. After the bubo has been well opened by means of a curved bistoury, and thoroughly washed out with an antiseptic solution, a mixture of iodoform and vaseline (one-sixth iodoform), having been liquefied by heat, is injected in the cavity; then cold applications of wet bichloride cotton are made in order that the vaseline may solidify around the opening of the wound. A speedy and complete cure is said to have resulted in every case, suppuration being completely arrested. In chancroidal buboes the same treatment was found to be most effectual.

Treatment of Tabes by Suspension.—At the last meeting of the Neurological Society of Berlin, PROF. BERNHARDT reported the results of 220 suspensions in 19 cases of tabes. He concludes that suspension by means of Sayre's apparatus is a most valuable therapeutic agent in this disease. In almost every case he observed a decrease, if not disappearance, of the lancinating pains, improved walk, a diminution of ataxic symptoms, strengthening of the functions of the bladder, and improved mental and general physical condition.—*Deutsche med. Woch.*, May 16, 1889.

An Application for Boils.—DR. HALLE, in *L'Union méd.* of May 14, 1889, gives the following prescription, which he claims, when used according to the directions given below, never fails to abort boils:

℞.—Tincture of arnica flowers . .	f ℥ijss.
Powdered tannic acid)	
Powdered gum arabic) .	āā ℥jss.—M.

Paint the boil and the surrounding skin with this mixture every five minutes until the coating becomes thick and hard; the pain will immediately disappear.

Sweating Feet.—The fetid sweat of the feet, so frequently met with, may be quickly cured by the following simple procedure: Soak the soles of the stockings to be worn on the following day in a three per cent. solution of boric acid, and allow them to dry during the night. The stockings should be changed at least every other day, and the feet kept clean. The most stubborn cases will yield to this treatment.—*Monatsheft für Prakt. Derm.*, May 1889.

Chloroform Inhalations in the Treatment of Severe Forms of Pneumonia.—DR. CLEMENS, in the *Allg. med. Centr. Ztg.*, No. 21, reports forty-two cases of severe forms of pneumonia, which were treated exclusively with inhalations of chloroform. According to the author, these inhalations not only immediately alleviate all pain, but also cut short the duration of the disease itself. Indeed, in most cases after a continuous use of this remedy for twelve hours a considerable and rapid fall of temperature was noted.

Unfavorable symptoms resulting from its use the author claims never to have observed, provided the chloroform had not undergone decomposition. For these inhalations the chloroform is diluted with alcohol. The severer the case the greater the quantity of alcohol, as longer use of the remedy is necessary. Clemens' method of administering the drug is as follows: a small ball of lightly wound cotton is allowed to absorb about two or three drachms of the alcoholic solution of chloroform. This is then wrapped in loose cotton and held within about an inch of the face. The inhalations should be interrupted from time to time.

In substantiation of the value of his method of treatment, Clemens claims not to have lost a single case of inflammation of the lungs during a practice of forty-two years.

Snuff for Coryza.—SIR MORELL MACKENZIE recommends the following snuff in cases of coryza:

℞.—Sulphate of morphia . . . gr. ij.
Subnitrate of bismuth . . . ʒj.—M.

Small quantities of the powder should be snuffed up into the nose during the first forty-eight hours of the affection.—*L'Union méd.*, May 18, 1889.

Hemorrhoids Treated by Dilatation of Anus and Rectum.—PROF. SCABBOTIN, says the *Prager med. Wochenschrift*, April 17, 1889, recently claims to have radically cured sixty-one cases of hemorrhoids by forcible dilatation of the anus or rectum. A "Trélat dilator" was used for the purpose. No unpleasant symptoms were ever observed to follow the operation.

Hypodermatic Injections of Blood in Anæmia.—DR. H. WESTPHALEN, in the *Centralbl. für Therapie*, No. 5, 1889, reports a case of extreme anæmia which was cured by subcutaneous injections of blood, according to Ziemssen's method. The case was that of a man, aged thirty-six, whose blood was extremely poor; the number of red corpuscles being only 840,000 to the cubic millimetre. Tonic treatment had been pursued for some time previous but to no avail.

About five ounces of blood were taken from the median vein of a healthy subject, caught in a vessel and defibrinated by stirring with a glass rod, then strained through gauze to remove the larger particles of fibrine, and then injected under the skin of the thighs; about six or seven drachms being injected at each puncture. Then the limbs were vigorously rubbed and manipulated in the direction of the lymphatic stream. The absorption of the blood was complete. No unpleasant symptoms followed the operation. The next day the pulse, which had been 100, dropped to 80. Eight days later the patient's blood was examined and found to contain 1,240,000 red blood-corpuscles in a cubic millimetre. In one month he was pronounced cured.

Unpleasant Symptoms Following the Use of Sulphonal.—DR. PAUL REHM reports to the *Berliner klin. Woch.*, No. 16, several cases in which most unpleasant symptoms were observed to follow the use of sulphonal. In one case, in which the drug was given in eighteen-grain doses for muscular rheumatism, it acted well for the first three doses, after which symptoms of fatigue and depression manifested themselves. The drug still being continued, these symptoms were followed by constipation, loss of appetite, intense physical and mental restlessness, excitement, fear, a feeling of dizziness when the eyes were closed; later, painful hallucinations and depression. Dr. Rehm, when he called, found the patient in an almost collapsed condition, face pale, pupils contracted, speech scarcely audible; pulse weak, over 100; ischuria, hyperæsthesia of the senses, sight double, muscular contractions, etc. The patient was wholly unable to move, and two weeks later was only able to walk with a staggering gait. Dr. Rehm also reports several other cases in which similar, although not so intense, symptoms were observed to follow the use of moderate doses of sulphonal.

A New Soap for Scabies.—At the last meeting of the Therapeutic Society of Paris, DR. CONSTANTIN PAUL gave the following formula for a "scabies soap":

℞.—Soap . . . . . 100 parts.
Petroleum } . . . āā 50 "
Alcohol }
White wax . . . . 40 " —M.

If the body is well washed with this soap two or three times a day, the scabies will disappear in two or three days.—*Wiener med. Presse*, May 12, 1889.

Perfumed Chloroform.—In cases in which the administration of chloroform produces vomiting, or is otherwise badly tolerated, DR. NUSSBAUM, in the *Revue de Thérap. méd.-chir.*, of May 15, 1889, advises the use of chloroform perfumed with oil of cloves. He claims to have repeatedly used the anæsthetic thus perfumed in the most sensitive cases, without its ever causing vomiting. The possibilities of casualties resulting from the use of chloroform are said to be greatly lessened by perfuming it.

The Treatment of Metrorrhagia.—DR. ROKITANSKY has found the following most efficient in cases of metrorrhagia:

℞.—Extract of ergot . . . . ʒjss.
Cinnamon water . . . . fʒvj.
Syrup of bitter orange rind } āā fʒss.
Rum (good quality) }
Salicylic acid . . . . . gr. viij.—M.

Dose, a teaspoonful three times a day.—*Revue de Thérap. méd.-chir.*, May 15, 1889.

Fœtal Infection by Typhoid Bacilli.—The question as to whether or not the typhoid bacilli can infect the fœtus has been actively discussed of late. A case which was lately reported by DR. T. C. EBERTH, and referred to in the *Centralblatt für Bakter. und Parasit.*, May 3, 1889, apparently settles the question. A woman, aged thirty, in the fifth month of pregnancy, was taken with typhoid fever and miscarried. The fœtus was at once subjected to a most careful examination, and in the cardiac blood, as well as in the secretions of the lungs and spleen, the bacilli were found. Strange to say none were discovered in the liver. The bacilli thus procured were transferred to cultures (potatoes, gelatine, etc.), and developed further bacilli. That these microörganisms were true typhoid bacilli Eberth does not alone state upon his own

responsibility, but also upon the unanimous opinions of eminent bacteriologists.

Formulæ for Creasote.—On account of the disagreeable taste of creasote, its internal administration is advised in the form of capsules. Still there are other forms of prescribing it which are useful. The following are given by DR. KEFERSTEN, in the *Gaz. hebd. de Méd. et de Chir.*, May 10, 1889, and although not new, may be found valuable:

I. The usual formula for creasote capsules is:

℞.—Creasote . . . . . ¾ gr.
Balsam of tolu . . . . ⅓ gr.—M.

The above is for one capsule. Average dose, three capsules a day.

II. The following emulsion of creasote well replaces cod-liver oil and creasote:

℞.—Oil of sweet almonds . . f℥v.
Creasote (beech-tree) . . f℥ij.

Dissolve and add

Gum arabic . . . . ℥jv.
Dist. menthol water . . . f℥xvij.—M.

About a tablespoonful may be given from two to five times a day.

III. Under the title of "creasote drops" Kefersten gives the following:

℞.—Creasote . . . . . ℥j.
Tincture of cinnamon . . f℥jss.

The average dose is fifty drops daily in port wine.

IV. In cases in which there is cough and diarrhœa the following pills will be found most valuable:

℞.—Creasote . . . . . 31 grains.
Acetate of lead . . . 4 "
Extract of opium . . . 3 "
Syrup of sugar . . } āā q. s.—M.
Gum arabic . . . }

Make into one hundred pills. Dose, five to six pills three times a day.

V. Lastly, Kefersten recommends "creasote potion," as given below:

℞.—Creasote . . . . . 15 grains.
Alcohol . . . . . f℥vj.
Syrup of cinnamon . . . f℥ivss.—M.

Dose, about two dessertspoonfuls a day; this may be gradually increased as deemed advisable.

Carbolic Acid Spray in Whooping-cough.—DR. E. MAURICE reports to the *Journal de Méd. de Bordeaux*, No. 36, several cases of whooping-cough which he has treated most successfully with carbolic acid spray. A five per cent. solution is used, and about a quart sprayed at three different intervals during the day. The paroxysms of coughing are immediately relieved and the duration of the disease materially lessened.

Plastic Operation in Open Cancer.—To change an open cancer into a covered cancer, DR. P. KRASKE, in the *Centr. für die med. Wissensch.*, May 18, 1889, advises the following method of procedure, which he has used successfully in three cases. After the surface of the cancer has been freshened by means of a sharp scoop or knife, a flap of healthy neighboring skin is brought over the surface of the cancer and fixed in place by a few stitches. If the surface of the cancer has been well freshened, and if the operation is conducted according to strict antiseptic principles, healing by first intention may be expected. Skin grafts should be made upon the exposed flesh from which the flap was taken.

Application for Warts.—The following is quoted from the *Gaz. med. Lomb.*, May, 1889, and is claimed to be very effectual:

℞.—Acid salicylic . . . . grains 15.
Alcohol . . . . . ♏xvj.
Ether . . . . . ♏xxxx.
Collodion . . . . . f℥jss.—M.

Apply daily to the warts.

Treatment of In-growing Nails with Tinfoil.—DR. THEODORE CLEMENS, in the *Thérap. Monatscheft* for May, 1889, highly recommends the treatment of in-growing toe-nails with tinfoil packing. The process is merely to pack under the sharp edge of the in-growing nail one or two thicknesses of common tinfoil with the aid of a small pincette. The treatment, which after the first time the patient can readily undertake himself, is painless, and need be continued for a few weeks only; in which time it will only be necessary to renew the packing about four or five times. Clemens claims that the tinfoil acts chemically as well as mechanically—its composition being iron, copper, arsenic, molybden, wolfram, and bismuth. In cases of in-growing nails occurring in patients suffering with hereditary syphilis, the remedy acts with special efficacy.

Toothache Drops.—

℞.—Morphine acetate . . . . grain 1.
Oil of peppermint . . . gtts. v.
Phenol . . . . . gtts. xx.
Collodion . . . . . f℥j.—M.

Apply with cotton.—*Journ. de Méd.*

The Etiology of Scarlet Fever.—An interesting series of experiments, relating to the etiology of scarlet fever, has recently been carried out by DR. MARIE RASKIN, of St. Petersburg. The results of her researches, which appear in the report of Third Congress of Russian Physicians in St. Petersburg (*Central. für Bakt. und Paras.*, May 10, 1889), are as follows:

The micrococcus scarlatinæ, as described by Klein, she has found to be a streptococcus, and identical with the streptococcus pyogenes. The scarlet fever bacillus, described by Edington, was only found in four cases out of one hundred. However, in every case, Dr. Raskin found a new and as yet undescribed micrococcus. It is of an irregular form and varies in size. It grew well in cultures of agar or gelatine. When found in pairs, the one was invariably larger than the other. The coccus was found in the blood, parenchymatous organs, and also in the skin flakes of the patient. In the blood it was only observed during the first four days of the disease, and then always enclosed in the white blood-corpuscles. Moderate warmth was necessary for its growth in cultures.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE . . . . . $5.00.

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JUNE 22, 1889.

THE MORTALITY AMONG NURSES.

THE advocates of the non-bacillary origin of tuberculosis have sought support for their position in the immunity often enjoyed by nurses and attendants on the phthisical. That this immunity is the exception and not the rule seems indicated by recent studies by CORNET, whose rules for the prevention of tubercular infection have been adopted by the German Government, and were published in THE MEDICAL NEWS of May 25th (page 572).

In the *Zeitschrift für Hygiene*, Sechster Band, 1889, Cornet publishes the tabulated results of his comparison of the mortality rates in the population of towns and cities and in nurses. A large proportion of German nurses are members of religious orders who by reason of their secluded, regular lives are removed from many causes of acute disease. Such nurses are in the best mental and moral condition to insure health, for which and other reasons the infective diseases ought not to be especially prevalent among them. Care was taken to select orders whose members serve for life and remain celibate.

The material collected was from 38 cloisters, embracing an average yearly service of 4028 women, whose aggregate service in years was 87,450. An examination of this material during 25 years revealed 2099 deaths, 62.88 per cent. of which were from tuberculosis, or nearly two thirds; the usual proportion of deaths from tuberculosis is from one-seventh to one-fifth. Next to tuberculosis comes typhoid, while cancer shows a slightly increased rate of mortality. Death occurred among these nurses at an average age of 36.27 years, an average shorter life than that of workmen exposed to the inhalation of injurious dust, by eight or ten years.

The death-rate from tuberculosis among nurses attains its maximum between the thirtieth and fortieth years, and then steadily declines. When a comparison of the death-rate of nurses and the population of a town is made, it is found that between the ages of 15 and 20 the mortality among nurses is four times that of other population; from 20 to 30, three times; from 30 to 40, twice as great, afterward becoming about equal. The explanation of these facts is found in the prevalence of tuberculosis among nurses, it being nine times more frequent than among other classes. All infectious diseases are more frequent among nurses until the fortieth year of life, after which their death-rate is lower than that of other classes.

It is further shown that during the first six months of service the nurse enjoys comparative immunity from infection; after that the mortality and morbidity rate steadily rises for three years, during which the greatest number of deaths occur. The life chances of nurses do not compare favorably with others; a nurse beginning her profession at seventeen has twenty-one and a half years of life less than a woman of the same age not exposed to infective diseases; so far as relative age is concerned, a nurse at twenty-five has the chance for life commonly enjoyed at fifty-eight; at thirty-three years the outlook of a person aged sixty-two.

This sombre picture, however, is not drawn equally of all hospitals. There are those in which the nurse enjoys a far better sanitary environment, but that these are comparatively few may be realized from the fact that, out of twenty-one hospitals, in fifteen tubercle bacilli in a virulent condition were found upon the walls and beds and bedding.

The practical importance of these studies is self-evident. It is well known that tubercular infection is most frequently conveyed by the inspiration of dried sputa. If the patient expectorates into a vessel containing water, and the sputa fall into the water and do not dry upon the sides of the vessel, upon the bed, wall, or floor, the first source of infection is largely avoided. Especial care should be taken to avoid the retention of sputa in towels, handkerchiefs, and bedding; it is a common practice among

the phthisical to expectorate upon a handkerchief, which is often placed beneath the pillow. Those who handle such infected articles after the sputa have dried are especially liable to infection.

Until those who deny the infectious nature and bacillary infection of tuberculosis offer demonstrative proof of greater scientific weight than that advanced by Koch and others, it is the duty of the practical physician to act upon the belief that tuberculosis is infectious, and to guard against its infection; fortunately the measures necessary for the protection of nurses are possible in all well-regulated hospitals and among intelligent families, and these measures should be strictly enforced.

RESECTION OF THE RECTUM.

THE operation of resection of the rectum, for the removal of high-seated growths, has been performed of late years more frequently and attended with greater success than formerly. Still, the methods principally employed are by no means all that could be desired. One of their chief drawbacks is the fact that the coccyx is always sacrificed, and through this procedure the pelvis robbed of a most important support. The result frequently is incontinence of feces and prolapse of the rectum. HEINECKE (*Münchener med. Wochenschr.*, No. 37, 1888) advises a temporary resection of the coccyx and of the lower end of the sacrum. His method is very complicated and necessitates two operations. Kocher, who has had large experience in rectal surgery, has always found it necessary to resect the coccyx, and Kraske (*Langenbeck's Archiv*, 1886, vol. xxxiii., No. 3) is of the same opinion. A most practicable method has, however, been brought forward by DR. WILLIAM LEVY, of Berlin. He holds (*Centralblatt für Chirurgie*, No. 13, 1887) that the floor of the pelvis and the sphincter should not be incised if possible. The question naturally arises, Is it possible to reach high portions of the rectum without cutting through the floor of the pelvis or dividing the sphincter? To solve this satisfactorily, Levy began a series of experiments upon the cadaver, and finally struck upon an entirely new method of conducting the operation.

The first incision is made horizontally across the sacrum, about one-half inch above the cornua coccygea. This incision should be about four to four and one-half inches in length and should reach to the bone. From the two extremities of this incision two cuts are extended downward, about four inches, through the entire thickness of the gluteus maximus. In one of these perpendicular incisions a wide blunt hook is inserted and the muscle pulled well outward, the lateral portion of the posterior sacro-sciatic ligament is laid bare, and both the posterior and anterior sacro-sciatic ligaments are divided close to the edge of the bone in the direction of the horizontal incision. The same procedure is then carried out on the other side. Now, by means of an elevator, the connective tissue on the anterior wall of the sacrum is freed, and between the elevator and the bone the blunt end of a pair of bone scissors is introduced and the sacrum cut through. The skin flap, with the piece of bone attached, is then pulled down, by means of a strong hook, and a large portion of the rectum will be brought into view. Through this opening, after the connective tissue has been loosened, one is able to reach downward to within three-quarters of an inch above the sphincter and upward to the sigmoid flexure. If, on account of the magnitude of the growth, it is still necessary to cut away more of the sacrum, it may easily be done without interfering with the base of the pelvis.

Of the conclusion of the operation little need be said. The resected bowel should be closed with a double row of sutures, the flap is then brought back into its original position, the excised portion of the sacrum fastened in place by bone suturing, and the horizontal incision closed. The perpendicular incisions may either be packed with iodoform gauze or else closed, except at the lower extremities, which should be left open for drainage. Irrigation may be used for a few days or an antiseptic dressing at once applied.

The great advantage claimed for this operation is that it will leave the patient in full possession of the normal function of the lower bowel. Since the sphincter has not been touched, nor the base of the pelvis robbed of bony support, incontinence of feces and prolapse cannot occur, and the probabilities of an ultimate recovery are greatly enhanced.

THE American Medical Association meets at Newport on Tuesday, Wednesday, Thursday, and Friday of next week, and there is every indication of a large, interesting, and unusually instructive meeting. Several amendments to the constitution, which are printed in another column, will come up for action, and on account of their importance should receive careful consideration. The one providing for a General Committee, proposed by Dr. N. S.

Davis, has very important bearings upon the future mode of conducting the business of the Association.

THE American Neurological Association meets at the West End Hotel, Long Branch, on June 26th, 27th, and 28th.

OUR excellent contemporary, *The Weekly Medical Review*, of St. Louis, evinces its enterprise by announcing that on the first of July it will be enlarged to the size of the *New York Medical Journal*. It also states that another weekly medical journal is about to enter the field in that city.

The Medical Press of Western New York, which has been published for nearly four years under the able editorial management of Dr. Roswell Park, states. in its June issue, that the circumstances which called it into existence no longer exist, and that it has been merged into its older contemporary, *The Buffalo Medical and Surgical Journal.*

M. LOUIS PASTEUR accepted the invitation of the Council of the Royal Society of England to deliver the Croonian Lecture on June 3d, but on account of his ill-health, M. Roux was obliged to read it for him. His subject was "Preventive Inoculation." He stated his belief that the best explanation of the problem of immunity consisted in considering it as the result of the habituation of the white blood-corpuscles to the poisons secreted by the microbes. "When the virus begins to develop in the body of an animal subject to the malady it forms its poisons, and when the white corpuscles begin to struggle against them their activity is arrested by this toxic production. The microbe continues to develop, and the malady progresses. But in the case of an animal rendered refractory by previous injection of the soluble substances, or by inoculation of attenuated virus, the corpuscles have already got accustomed to the microbic poison, and since the small doses given at the beginning of the cultivation of the virus do not impede their activity, they commence the struggle and devour the parasites."

WE greatly regret to learn that Dr. T. G. Richardson has felt obliged on account of ill-health to resign the professorship of Surgery in the Tulane University, New Orleans, which he has so ably filled for an unusually long period. Two years ago, while travelling in Southern Europe, Dr. Richardson contracted an alvine flux from which he has never since been entirely free, although at present he is much better and has encouraging prospects of recovery.

Upon the acceptance of his resignation his colleagues of the Medical Faculty adopted the following complimentary resolutions:

Whereas, Prof. T. G. Richardson, who has served the medical department thirty-one years—fourteen as professor of anatomy and seventeen as professor of surgery, including twenty years as dean—has urged the acceptance of his own resignation because of ill-health; therefore, be it

Resolved, That Prof. Richardson's resignation is accepted with the utmost regret, this faculty being thereby deprived of its most valued member and its wisest counsellor.

Resolved, That the members of this faculty can never forget that his inflexible devotion to truth, honor, and duty furnished for their guidance the highest and noblest standard of true manhood; that his ability and experience as a teacher placed him in the foremost rank of medical instructors; that his wisdom as dean successfully guided the destiny of the medical department through many years of its severest trial, and that to him more than to any other is due its present prosperity.

Resolved, That while deeply deploring the necessity that withdraws from active service our senior professor, yet our hearts are revived by the hope that time and rest will restore him to health and give to him many happy and useful years wherewith to bless his family and his friends and to benefit all of his fellow-citizens.

Resolved, That Dr. T. G. Richardson is hereby chosen emeritus professor of surgery.

Prof. Samuel Logan, Emeritus Professor of Anatomy, has been selected to fill the chair of Surgery rendered vacant by Dr. Richardson's resignation.

THE Medical Society of New Jersey held its one hundred and twenty-third annual meeting at Asbury Park, on June 18th and 19th, under the presidency of Dr. H. Genet Taylor, of Camden.

THE College of Physicians and Surgeons of New York, at its commencement last week, conferred the degree of M.D. on 166 graduates, the largest class in the history of the College. The total number of matriculates is said to have been 800. Dr. James W. McLane has been elected to succeed the late Prof. John C. Dalton as President of the College.

AT the meeting of the New York Academy of Medicine held on Thursday evening, the plans for the new building were presented and described by the architect, Mr. R. H. Robertson; and, as this was the last meeting before the summer adjournment, after the meeting there was an informal reception and collation.

LADY KORTRIGHT, formerly of Philadelphia, but now living in England, has presented $100,000 to the Presbyterian Hospital at Philadelphia, to found a Convalescents' Retreat. She has also given to the same hospital $40,000 to build a male surgical ward, and $10,000 to endow two perpetual free beds.

THE attention of the Iowa State Board of Health has been called to the important question of river pollution alleged to be due to sewage containing sulphuric acid. The question bears upon the present condition of the Iowa River in the vicinity of Tama City and Marshalltown, due to the poisoning of myriads of fish by the refuse flowing from certain glucose works located at the latter town. The fish thus destroyed have, by accumulating and putrefying, become a nuisance injurious to so large a river-side population as to demand the interposition of the State authorities. The people living along the stream have made efforts to clear it of the dead fish, in the hope of procuring relief, but the masses of them were too great to be removed in this manner. There is rapidly becoming a necessity for general legislation in this country to prevent the pollution of our rivers.

THE Astley-Cooper prize, amounting to $1500, will be awarded in 1892. The question proposed is, "The Influence of Microörganisms upon Inflammation." The papers of those contesting for the prize should be written in English, or accompanied by an English translation, and should be addressed, before January 1, 1892, to Guy's Hospital, London. The prize will not be awarded to two or three working together.

PROF. AUGUST BREISKY, the well-known Viennese gynecologist, died on the twenty-fifth of May, after a protracted illness. His loss will not only be felt in Vienna, but by the medical profession in general. He was a man of rare capabilities, an excellent writer, a lucid lecturer, and a most enthusiastic student. His manner was quiet, unassuming, and gentle, admirably suited for his chosen specialty. Breisky was born in Bohemia in 1832, was graduated in medicine at Prague in 1855; after serving as assistant to Treitz, and later to Seyfert for several years, he began practising, but in 1866 was called to a professorship in the Salzburg school and in the following year he was transferred to Berne where he remained seven years. In 1874 he was elected Professor at the University of Prague, where he remained until 1886, at which time he came to Vienna to take the Gynecological chair at that University rendered vacant by the retirement of Späth.

SOCIETY PROCEEDINGS.

PHILADELPHIA ACADEMY OF SURGERY.

Stated Meeting, May 6, 1889.

THOMAS G. MORTON, M.D., IN THE CHAIR.

DR. CHARLES B. NANCREDE presented the specimen from a case of

EXCISION OF THE OS CALCIS,

which had two points of interest. The first is, that it is somewhat unusual to remove the os calcis in its entirety, and the second is the difficulty that was experienced in its removal. The patient was a child, ten years of age, with the ordinary history of strumous bone trouble. Examination showed that the probe entered the substance of the os calcis. He made the Ollier incision for the removal of the entire bone, and was able to get around it to a certain point. When he attempted to separate its connections with the astragalus, he found bony ankylosis between the two bones, requiring the use of bone forceps. The removal of the bone in its entirety has certain advantages over the removal piecemeal. No fragments are left behind, and if there is any advantage in leaving the periosteum, it can be done better than by the other method. The specimen shows a distinct epiphysial abscess of the os calcis near the attachment of the tendo Achillis. This is the second time that he had performed this operation. The first was done nearly thirteen years ago, and the man is able to walk with perfect ease. All that he needs to do is to fill up the heel of his shoe with a wad of newspaper.

DR. SAMUEL ASHHURST asked if all the caries could not have been removed without the removal of the entire bone? He had in mind several cases in which, under the use of Vilette's fluid, patients have entirely recovered without operative interference. He recalled one case treated in this way twenty years ago who is still perfectly well.

DR. NANCREDE thought that, if modern views are correct in regard to these bone affections—viz., that they are of a strumous nature—that struma and tubercle are the same so far as can be distinguished clinically, it is desirable that we should, if possible, get rid of the entire disease. It is well known that rough attempts to remove tubercular bone may favor an outbreak of acute tuberculosis. If this operation was followed by bad results and subjected the patient to great risks, that would be more in favor of the use of solvents, but such is not the case. The space left is filled with dense fibrous tissue, and the result, both from a cosmetic and useful point of view, is admirable. He had tried solvents, but with very poor results, in other bone cases.

A few days ago, Dr. Simes assisted him with an operation on a femur, where he is sure that the disease is tubercular, and which admirably illustrates the necessity of free removal of bone in tubercular disease. He trephined opposite the opening of an old bone abscess, and cleared out the medulla until firm and solid bone was

reached. The bone was so thickened for two inches above this point that it was agreed that the trephine should be applied there. This was done, and the whole medulla found diseased here also. From this he broke through into still a third caseous space. Attention has been recently called, by Dr. Senn, to the fact that in tubercle of the long bones there may be disease an inch or two above the point indicated by external appearances. Probably one-half of the cases said to be relapses are really insufficient original operations which failed to reach all diseased foci.

DR. WILLIAM HUNT said that ten years or more ago, he made an incision over a sinus in almost the same position as in the specimen shown. He removed a marble-shaped piece of necrosed bone, cleaned out the cavity, and restored the flaps, making provision for drainage. The operation was performed in a boy of sixteen, in good condition, although there was a tubercular history in the family. The wound healed perfectly, and the individual is now in perfect health. He, however, in the main, agrees with what Dr. Nancrede has said. He had seen admirable results from the entire removal of the bone.

DR. SAMUEL ASHHURST then exhibited

A CURVED DIRECTOR TO BE USED IN THE PERFORMANCE OF TRACHEOTOMY.

He said it was a suggestion looking toward a new instrument rather than a perfected instrument. Most surgeons have probably found difficulty in uncovering the trachea with the ordinary director in performing tracheotomy, especially in children where the space between the chin and the sternum is very limited. If we are going to open below the thyroid isthmus, the space which we have is not more than one-half inch, no matter how free the superficial incisions may be. Operating under such circumstances curved directors have been used, and in this way the tissue covering the trachea was lifted. It occurred to him that a director made of a shape similar to the ordinary aneurism needle, and with a groove on its concavity, would facilitate the operation, and he had devised such an instrument. He had used it but once, and that was in one of the deepest tracheotomies that he had performed, the trachea when uncovered being fully one and one-half or one and three-fourths inches below the surface. In this case it worked very well.

DR. NANCREDE asked why it was that the high operation is not more frequently performed in this country. This operation is very simple, and it is impossible to injure any vessels of size. The only thing likely to be cut is the transverse communication between the thyroid veins. The incision is made from about the middle of the thyroid cartilage down to the point where it is proposed to insert the tube, probably about the second or third ring of the trachea. The superficial fascia is then divided, and we reach the superficial layer of the deep fascia. An ordinary eye speculum is now inserted. Then a transverse incision is made over the cricoid cartilage, cutting through the coalesced layers of the deep fascia. We can then work downward, having everything perfectly and safely enclosed in the two layers of the deep fascia, and can insert the tube as low as in the other operation. The low operation may be indicated where we are looking for a foreign body, but in ordinary cases of croup or stenosis from other causes, he thought that the high operation answers every purpose. He believed that the risk of anterior mediastinitis is less after the high operation than after the low.

THE MONTREAL MEDICO-CHIRURGICAL SOCIETY.

Stated Meeting, May 17, 1889.

THE PRESIDENT, DR. WILLIAM GARDNER, IN THE CHAIR.

DR. FINLEY showed the organs of a patient, the subject of

MALIGNANT DISEASE OF THE STOMACH.

There was a growth on either side of the pylorus and the gastric walls were uniformly infiltrated. The mucosa was not ulcerated, and although the opening at the pylorus was only half an inch in diameter, there was no dilatation of the stomach. The pyloric growth was continuous with a nodule projecting into the hepatic flexure of the colon, causing puckering and moderate contraction of the lumen of the bowel. Microscopically there was inflammatory infiltration of the mucosa with much hyperplasia of the submucous and muscular layers. No cancerous elements had been found after examining a large number of specimens from different parts of the growth. The liver and heart were considerably atrophied, but no metastases were present. The absence of hemorrhage was explained by vomiting always during or after meals. The growth was doubtless of a malignant nature, as the cancerous elements are at times occluded by the fibrous elements of the growth.

DR. STEWART stated that the patient, a woman aged forty-six, had been subject to severe and frequent vomiting since June last, also had pain, but no hemorrhage. Moderate and progressive emaciation had accompanied the affection. A tumor was felt in the epigastrium, but there was no dilatation of the stomach. A diagnosis of pyloric cancer had been made.

DR. BELL exhibited a specimen showing

RUPTURE OF THE BOWEL FROM VIOLENCE.

The specimen was removed from a grown man, aged thirty-five, who was discharged from his employment on Friday, May 3d, with a considerable amount of money in his possession. He was taken up by the police on Saturday for drunkenness. Being unable to pay his fine, he was put in jail, where he was found dead in bed at five o'clock Sunday morning. He was a perfectly healthy man. A coroner's inquest was held and the verdict of "*Death from congestion of the lungs*" found. No post-mortem was held. He having no relatives, was sent up to the Anatomical Department of McGill's University, and there a post-mortem was held by Dr. Finley. A rupture of the ileum was found three feet from the ileo-cæcal valve. There was no ulceration. The eversion of the mucous membrane was well marked. There was also general plastic peritonitis. There were no marks of violence on the abdominal wall. Dr. Bell stated that when the man was taken to jail he complained of severe pain in the belly and could not walk, and he was prescribed for by the jail physician. Dr. Bell also said that he had no doubt that the man had been kicked to death.

DR. SHEPHERD said that this was another example of

the uselessness of coroners' inquests when held by an incompetent individual. In the museum of the medical faculty of McGill University was a specimen obtained a year or two ago from the dissecting-room. The man had been found in an unconscious state in the streets and was brought to the General Hospital where he died in a few hours. A coroner's jury brought in a verdict of death from apoplexy. The coroner refused a post-mortem examination. When examined in the college every rib was found broken, the whole twenty-four, and the specimen is now in the college museum. He considered this state of affairs most disgraceful and dangerous to the welfare of the community.

RIGHT SUBCLAVIAN ARTERY ARISING FROM THE DESCENDING AORTIC ARCH. RIGHT PULMONARY VEIN EMPTYING INTO THE SUPERIOR VENA CAVA.

DR. SHEPHERD exhibited a specimen obtained from the dissecting-room in which the right subclavian artery arose from the descending aortic arch opposite the third dorsal vertebra, passed up and to the right behind the trachea and œsophagus to its normal position in the neck. The recurrent laryngeal nerve did not hook round the right subclavian, but went directly to its place of supply. The right vertebral arose from the right carotid, about the point the subclavian arises. The left vertebral arose from the aortic arch between the left carotid and left subclavian. Dr. Shepherd said that this was a very rare anomaly, but its occurrence was easily explained by referring to the development of the vascular arches. It was an example of a persistence of the right aortic root; the fourth arch, from which the subclavian of the right side is usually derived, having atrophied and disappeared, unless we regard the right vertebral as the inner remnant of that arch. Both fourth and fifth arches having disappeared, the inferior laryngeal nerve would, of course, go directly to its destination without hooking round the subclavian, which, in this instance, is formed by the persistent right aortic root. There was a slight attempt at recurrence at the point the vertebral arose; this inspires the supposition that this vessel was the remains of the fourth arch.

Dr. Shepherd stated that he had reported many years ago in Vol. I. of the *Montreal General Hospital Reports*, a case of double subclavian, that is, a persistence of both the fourth arch and the right aortic root. The vessel representing the right aortic root was of small size and joined the true subclavian in its second portion.

In this same subject on the right side there was only one pulmonary vein of large size which emptied into the vena azygos major instead of into the left auricle. The continued vein was of large size, and hooking round the root of the right lung soon emptied itself into the superior vena cava. Dr. Shepherd said this was a very rare anomaly and he could find only one reference to it, viz., in Henle's *Anatomy*. In the same subject the renal arteries were multiple and there were many muscular anomalies, none of them of any great rarity. The composition of the teeth was peculiar in the upper jaw; the intermaxillary bones appeared to have been poorly developed, and the teeth of the upper jaw proper overlapped the incisors on each side, as if the growth of the superior maxilla had been greater than that of the intermaxillary bones. The patient was a woman, aged thirty, who died in the General Hospital of chronic phthisis.

DR. BULLER reported a successful case of

MULE'S OPERATION OF INSERTING AN ARTIFICIAL VITREOUS.

The patient, a boy aged eight years, was exhibited to the Society. The following is the history of the case: On the 11th of April last the boy was injured by a piece of wood thrown at him in play. Dr. Buller saw him for the first time on the 18th of the month. The eye was said to have been swollen for a few days, but had not caused him much discomfort, and he had been without treatment. The eye was found soft and shrunken, and there was a recently healed wound about half an inch long on both upper and lower lids. The wound of the eyeball had divided the cornea vertically in two parts and extended a short distance into the sclerotic at either end. There was no perception of light. All swelling of the lids had disappeared, and the conjunctiva was healthy; some tenderness and retraction of the scleral portion of the wound seemed to indicate danger to the other eye, and to avert this danger immediate operation was advised. Considering the youth of the patient, Dr. Buller preferred not to enucleate the eye, as he had found that the enucleation of the eyeball in childhood tended to a faulty development of the conjunctival sac and difficulty in ultimately wearing an artificial eye.

The boy being perfectly healthy, and evidently not predisposed to unhealthy inflammatory action, the case was considered one favorable for the performance of Mr. Mule's operation of inserting an artificial vitreous. This operation was done on the following day. The strictest antiseptic precautions were observed. The only difficulty experienced was that of arresting completely the hemorrhage from the under surface of the sclerotic; about fifteen minutes elapsed before the bleeding entirely ceased. The glass globe was then inserted. The smallest size of globe was used, so as to avoid tension of the parts where the sutures, three in number, were introduced. The scleral edges were brought into apposition in a vertical direction, the conjunctiva was united transversely over this, also by three sutures, and the eye again carefully cleansed with bichloride of mercury solution, 1 : 5000. The parts were then washed with iodoform and a pad of absorbent cotton applied over the closed lids; the dressing was kept in place by a firmly applied bandage covering both eyes. The dressing was allowed to remain undisturbed for forty-eight hours, and when removed the lids and orbital tissues were found considerably swollen and tender. This subsided in a few days under the constant application of cold-water compresses, and the case did remarkably well.

Two days ago an artificial eye was inserted, and the appearance of the patient was excellent; there was no sinking-in of the upper lid, and the movements of the eye are almost normal. As yet, the patient is only allowed to wear the eye for a short time each day. The appearance of the eye, the author remarked, was much more natural than could be attained by enucleation or optico-ciliary neurectomy, and it seemed probable that in his case all danger of sympathetic ophthalmia had been removed.

DR. MAJOR read a paper on

ADENOID GROWTHS OF THE NASO-PHARYNX.

He referred to the position advocated by Mr. George Stoker in operating. The patient's head should be on a

much lower level than the shoulders, so that the blood gravitates into and escapes by the nose. The reader of the paper also expressed his continued belief in the relations existing between nocturnal enuresis and mouth breathing. This opinion, first expressed in August, 1884, had since been confirmed by Dr. Ziem, of Danzic, and others. Dr. Magin stated that he had operated on 186 subjects for the removal of adenoid vegetations.

DR. BLACKADER said that since Dr. Major had drawn attention to the fact that enuresis and mouth breathing went together in children, he had closely observed many cases, and his experience did not go to confirm the observations of the reader of the paper. He had occasionally seen the two conditions associated, but the great majority of cases of enuresis observed were not in mouth-breathers.

DR. BULLER remarked that in the majority of cases operated on by him, he had found the fingers sufficient to remove adenoid growths from the naso-pharynx. The anæsthetic he found most convenient and least troublesome, was nitrous oxide gas.

DR. SHEPHERD reported a case of

SUBLINGUAL SEBACEOUS CYST,

in which he had recently operated. The patient was a girl aged nineteen years, who had first observed the growth some three years previously; latterly it had grown very rapidly, and projected considerably into the submaxillary space, causing an unsightly appearance. The girl had been several times insane, and once after the administration of ether, so no ether was given, but cocaine was injected into the skin beneath the maxilla. The cyst was opened in the mouth beneath the tongue, and it was the intention to pass a drain through the cyst and bring it out below the jaw. In pushing the dressing forceps through, it was found that the cyst wall was of considerable thickness, so it was seized through the opening made in the submaxillary region, and with occasional touches of the knife completely removed. The wound healed rapidly, and patient was well within a week. Dr. Shepherd remarked that this form of cyst was of considerable rarity and probably congenital. Being of slow growth, it was not noticed until sufficiently large to push up the tongue or to project externally. The cyst, as in the case narrated, usually contained inspissated sebaceous matter, which had much the appearance of putty. They were frequently mistaken for ranula.

DR. STEWART exhibited a case of

HODGKIN'S DISEASE.

The patient, a powerfully-built man, aged twenty-two years, first noticed enlargement of the glands on the left side of the neck ten months previously; the glands continued steadily to increase in size until the present time, when there was a very extensive infiltration on both sides of the neck and both axillæ. No other groups of glands were appreciably enlarged. Both liver and spleen normal in size. The patient was slightly anæmic, but there was no change in the absolute number of either the white or red blood cells, neither could any change in the size and shape of the red cells be determined. The patient had been taking for the past six months Fowler's solution of arsenic in considerable doses, but without any benefit.

CONGRESS OF THE GERMAN SOCIETY OF SURGERY.

Eighteenth Annual Session.
Held at Berlin April 24th to 27th, 1889.

(Specially reported for THE MEDICAL NEWS.)

(Continued from page 671.)

DR. ANGERER, of Munich, read a paper on

DIAGNOSIS AND OPERATION FOR PYLORIC STRICTURE.

He had made sixteen operations for pyloric stricture due to carcinoma or other diseases, which enabled him to make a few observations that may be useful in a diagnostic point of view. The first step is to find out if the tumor which is felt is united to the stomach or not; for this purpose he has produced an artificial inflation of the stomach by introducing bicarbonate of soda and tartaric acid, according to Ziemssen's method, or again, in filling up the stomach with air by means of a pump. By this process the contents of the distended stomach can be easily made out, and it becomes an easy matter to determine the seat and the relation existing between the tumor and the stomach. In the second place, we must determine whether the tumor is movable or if it is adherent to the neighboring organs. In palpating the tumor we do not find the exact location of the tumor. It is again the artificial inflation which gives us, in this respect, the needed knowledge on the subject; but we must be careful to mark with a colored pencil the contour of the tumor before and after the inflation; we must also not forget that normally the retracted pylorus is always displaced downward and to the right during insufflation of the stomach.

The adhesions of the tumor with the anterior wall of the stomach can be easily diagnosticated. The adhesions with the diaphragm and liver are recognized by the fact that the tumor takes part in the movements of these organs; these are a contra-indication to the operation. It is most difficult to determine an adhesion of the tumor to the pancreas. On a cadaver he has ligated the pylorus, fixing it at the same time to the head of the pancreas, and then produced an inflation of the stomach, and he had found that in those conditions the displacement of the pylorus was hardly apparent, but he observed a special inflexion of the stomach at the left of the pylorus. From a practical point of view he concluded that, after inflation of the stomach, if the tumor disappears, this indicates that its seat is on the posterior wall of the stomach; if the stomach remains immovable, we might admit that the stomach adheres to the pancreas, which is situated behind it. In such cases we must give up resection, but in performing gastro-enterostomy we may still be able to help our patients very much. He has made six times a typical resection of the pylorus; one of his patients, who was suffering from cicatricial retraction, is now in excellent health, and has been so for two years. Two of his operated patients died at the end of three weeks; three died within the first days after the operation; two died from collapse; one from peritonitis. In six cases he performed gastro-enterostomy; one of these patients, who was operated on several months ago, is now very much relieved. In another patient, a loop of the intestine was taken up by mistake in one of the sutures, and the patient died at the end of three weeks.

The other patients died a few days after the operation. Surgical interference in such cases would be more favorable if the operation were done earlier. Ether is preferable to chloroform in these operations.

DR. LAUENSTEIN, of Hamburg, said that we are quite unable to decide, in the majority of cases, what operation is to be performed, before laparotomy is done; whether we are to resect the pylorus, to perform gastrostomy, or gastro-enterostomy; for we do not know in advance whether we shall have to deal with a benign or malignant tumor. He has found that the preliminary washing out of the stomach diminishes the danger of collapse. In one case he observed the evacuation of fifty-four ounces of urine after the washing out of the stomach and the operation. Perhaps a part of the water thrown into the stomach is absorbed by the vascular system and fills it, so that we have an action which resembles the transfusion of a solution of common salt into the blood. If we do not admit that, in such conditions, the stomach can absorb water, we must admit, as an explanation for the abundant diuresis, that it is the result of a nervous excitation. As to the suture, he has given up silk, which has yielded him nothing but bad results. Out of nine patients on whom he performed gastro-enterostomy, two died immediately after the operation, seven lived for five to six months. In nine cases he excised the pylorus, five patients dying immediately after the operation. The results would certainly be much better, should we not allow the diseased condition to advance so far.

DR. SCHLANGE, of Berlin, then read a paper on

INTESTINAL OBSTRUCTION.

Two sets of patients who suffer from intestinal obstruction must be treated medically. They are: First, cases of obstruction due to peritonitis; secondly, cases of intestinal paralysis consecutive to an internal obstruction. For these two groups the medical treatment is preferable to the surgical treatment. The surgical intervention must be kept for any mechanical obstruction of the intestine, but in such cases the diagnosis must be established as soon as possible. Whenever we are able to distinctly palpate the intestinal loops, the abdomen being already swollen, the more right we have to suppose that the intestine is not yet paralyzed. The paralyzed intestine loses its rounded form, and then only do we observe the "barrel-shaped" abdomen. As long as paralysis does not reveal itself by this symptom, laparotomy can be performed without fear. But it is impossible to lay down general rules, for we must direct our steps according to the symptoms of each case. In a grave case of peritonitis, one operation only could be performed, and that is enterostomy, which could save the life of the patient. If we believe that the wretched state of patients is produced by the toxic ptomaines formed in the intestines, we must be sure to get them away, and, if necessary, to make several fistulæ instead of one, to obtain a complete elimination of the intestinal poisons.

DR. FISCHER, of Breslau, then read a paper on

TREPHINING FOR CEREBRAL TUMOR.

He related the case of a patient who, in 1880, suddenly developed epileptiform attacks, with paresis of the two arms. In 1887 he had aphasia and severe headache. The patient was trephined, but no tumor found. After the operation the patient's state was ameliorated, and the paresis of the arms disappeared. But, two months later, new epileptiform attacks set in, followed by paralysis of the upper extremities and the right foot, with violent headache. He then trephined again, and came across a tumor, which he immediately extirpated with his fingers; the wound was then packed. But, some time afterward, the patient again began to suffer from headache, and a tumor appeared at the point of trephining; the patient died comatose three months after the last operation. The tumor was a round-cell sarcoma.

PROF. HORSLEY recommended always the removal of a large piece of bone, so as to be more sure to fall upon the tumor. The tumor must be removed with the lancet, never with the curette or thermo-cautery. The essential part is to diagnose the seat of the tumor and its kind as early as possible. He did not admit the cure of cerebral syphilis by iodide of potassium. This is why he always resorts to trephining in cases of cerebral syphilis when, after a month's treatment by iodide of potassium, he obtains no result.

In Jacksonian epilepsy we often find cerebral lesions, and in such cases we must not use the internal treatment for a long time; it is better to resort to an explorating trepanning. In idiopathic epilepsy, with localized convulsions in certain regions, the cranium must be opened, the motor centre of the affected region found. The faradic current will help us to determine whether or no we are on the affected centre; if so, we should resort to incision immediately.

PROF. TRENDELENBURG, of Bonn, described the following method for the

CORRECTION OF NASAL OBLIQUITY

due to a fault in the osseous vault of the organ, and not in the septum: He first makes a bilateral incision, starting from the wing of the nose to the eyelid; secondly, an incision of the nasal bones, so as to immobilize them. The operation is a simple one, and gives satisfactory results.

DR. LAUENSTEIN read a paper on

TOTAL EXTIRPATION OF THE DISEASED CAPSULE OF THE ARTICULATION OF THE KNEE, WITH A PRESERVATION OF THE CROSSED LIGAMENTS.

He had operated by this method on a case of arthritis deformans of the knee, accompanied by fever and pains, a month ago; in the articulation he found rhiziform grains. Another patient, who was operated upon two years ago, has preserved good movement of the leg. The preservation of the crossed ligaments is for the purpose of saving the mobility of the joint.

PROF. KOENIG did not believe with Prof. Lauenstein, that the crossed ligaments of the knee play the important part he attributed to them, but we must feel ourselves fortunate to be able to cure a tuberculous arthritis of the knee, even if we must sacrifice the crossed ligaments.

DR. PETERSEN said that in a case in which, two years previously, he had extirpated the crossed ligaments, he found them in part reformed.

PROF. RYDYGIER presented two patients suffering from

RHINOSCLEROMA,

which is rare in Germany, but more common in Poland. This affection is constituted by a chronic inflammation,

cicatricial alterations, and nodular vegetation. This disease is due to a bacillus, cultures of which he presented. No curative treatment seems to exist for this trouble.

PROF. CREDÉ, of Leipzig, then read a paper on

THE SURGERY OF THE GALL-BLADDER.

He had made five operations on the gall-bladder during the past two years, every one terminating favorably. His first operation was made in two divisions, the others in one. If by detatching the gall-bladder from the inferior surface of the liver, a serious hemorrhage is produced, he does not hesitate to cauterize the liver with the thermo-cautery. He had observed that during convalescence his patient had a very surprising appetite and yet diminished in weight. A physiologist has observed the same phenomenon in dogs whose gall-bladder he had extirpated.

This great increase in the appetite is explained by the fact, that after the extirpation of the bladder, the bile flows continuously into the intestine, because there is no longer a reservoir which in the normal state throws an increased quantity of bile into the intestine during digestion. At this time there is, after the extirpation of the gall-bladder, not enough bile thrown into the intestine to produce an emulsion of the fats and render them absorbable, so that the greatest part of them passes out in the feces. After a time nature will replace the extirpated bladder by dilating the ductus choledochus, to form a sort of diverticulum, and then nutrition becomes normal again, for the fats can then be emulsified, and, consequently, absorbed.

The operations of the future, according to his experiments will be: The extirpation of the bladder if it is diseased. Ideal cholecystotomy, to take away the calculi which are in the way of the function of the bladder, while it is itself not diseased; the bladder is opened and the foreign bodies removed, the organ is then carefully sutured and returned into the abdominal cavity.

DR. THIEM had performed laparotomy on a patient to remove a tumor; when the extirpation was completed, he found in his way a second tumor, which on close examination proved to be the gall-bladder filled with calculi. He removed the organ, and the patient recovered rapidly and is well.

PROF. LANGENBUCH, of Berlin, thought it very difficult to lay down rules in regard to such operations, although he had made about twenty such operations. He insisted on the fact that we must not rely too much upon palpation as being a certain method to diagnosticate a dilated gall-bladder filled with calculi; the exploratory incision only will determine exactly with what kind of tumor we have to deal. In palpating this region, the external border of the large rectus muscle is apt to lead us into error in diagnosis. He operated on patients only in whom a disease of the gall-bladder is absolutely chronic, and who suffered for a long time from severe hepatic colics. In other subjects he prefers the internal treatment, which in many cases gives very good results. The statistics of such operations is not a very remarkable one or satisfactory as regards final results, but we still are unable to give a definite opinion on the subject.

The total number of cholecystotomies reported amount to 73 in number, with 11 cases of death, 46 complete cures, 16 incomplete cures, with a persistent biliary fistula. Out of 24 personal operations, 2 died from intercurrent disease—that is, 1 from disease of the brain, and the other as a result of the biliary calculi; of the 22 remaining cases, 2 have died as a result of peritonitis, the others were cured.

PROF. KUESTER said that whenever these patients have not been too stout, he had been able to make a correct diagnosis by palpation alone, without an exploratory incision. The ideal cystotomy, followed by buried sutures, deserves to be recommended.

PROF. LANGENBUCH said that an ideal cystotomy presents a very serious danger. The ductus choledochus reacts to any excitation in a very remarkable manner; this is the reason why this canal becomes swollen after the excitation caused by the operation, the tumefaction preventing the free flow of bile, there is a regurgitation of it, and the bladder fills up; finally, the sutures give way, and the bile is thrown into the peritoneum and the patient dies.

PROF. CREDÉ said that this danger is greatly reduced if for several days we have recourse to drainage, and only close the gall-bladder later, when the irritative phase has passed.

PROF. MIKULICZ, of Kœnigsberg, then read a paper on

THE SURGICAL TREATMENT OF PERITONITIS FROM PERFORATION.

To ameliorate the results of the operative treatment of purulent peritonitis from perforation, cases only must be operated upon in which the diagnosis has been correctly and clearly established, and those in which the physical condition is good. In regard to the certainty of diagnosis, the different cases must be distinguished according to the point of departure of the peritonitis; secondly, according to the clinical course of the disease. Two forms of peritonitis by perforation are observed, according to the clinical course of the disease. One of these is diffused from the first, and runs a very rapid course, is very acute, and could be called diffused septic peritonitis. In this case collapse occurs very early, and laparotomy performed on such dying patients is useless. In a second form of peritonitis by perforation, which he has named progressive fibrino-purulent peritonitis, chances of cure after laparotomy are very much greater. This form is recognizable by the fact that it involves only a very limited portion of the peritoneum, from from which it extends to the rest of the serous membrane. Physicians often reproach surgeons for destroying, in performing laparotomy, the barrier which nature has opposed to the extension of the inflammation, and for transforming in this manner a localized or partial peritonitis into a general or total peritonitis. This reproach is sometimes correct, and to prevent it we must be careful not to destroy the fibrinous adherences which form between the visceral and parietal layers of the peritoneum and the serous membrane of the loops of intestines. This is the reason why we ought to make as many isolated incisions as we have foci of inflammation separated from each other by adherences; the pus must be drawn separately out of each one.

He had made eleven laparotomies for peritonitis by perforation: the seat of the operation was five times in the ileo-cæcal appendix, with two cures; in the small intestine five times; in the stomach once. The two

cases of perforation of the cæcal appendix cured were typical cases of progressive fibrino-purulent peritonitis. In one of these patients he evacuated the pus from six isolated pockets by making three incisions; the intestinal loops adhering one to the other were left untouched. For several days the patients must be carefully watched, so as to immediately discover any new formation which might have been overlooked during the first operation. We can be assured of the good results of intervention only when there is no elevation of temperature.

In the first of his two cases there existed between the first and last incision an interval of two weeks. The first incision was made in the neighborhood of the seat of the perforation. After the evacuation of the pus he washed the cavity out with 75 per cent. of sodium chloride instead of using antiseptics. When we find the perforation immediately it must be sutured, but if it cannot be rapidly found we must not spend too much time in hunting for it. The washed cavities are filled with iodoform gauze, and without inserting any drainage-tube, the wound is closed with flying sutures, the object of which is to prevent a prolapse of the intestine during cough, vomiting, etc. The patients are then treated by opium, with the addition of a severe régime.

PROF. KŒNIG, of Gottingen, said that the most important of intestinal perforations are those produced by fire-arms. Up to date, American surgeons, especially, have had more often the opportunity to study such cases. They admit that eighteen hours after the wound has been inflicted death is certain, and that the treatment becomes useless. The prognosis is more favorable when the intervention is early. For his part he had had to treat six cases of perforations due to stab-wounds. In one case a workman received a stab-wound of the abdomen with intestinal perforation. He operated fourteen hours after the traumatism, and his patient was saved.

PROF. ROSENBERG said that in a case of peritonitis by perforation, which remained circumscribed, he had opened the abdomen, as directed by Mikulicz, and one purulent pocket after the other, without even washing them, and the patient was cured.

DR. WAGNER, of Kœnigshütte, said that in a typhoid fever patient who presented all the symptoms of perforation he performed laparotomy eight hours later, and the patient was cured. On the other hand, he had lost a patient who had had several traumatic perforations, but he was only able to interfere eighteen hours after the accident; he sutured three intestinal wounds. The patient died fourteen hours later from collapse.

DR. MANTEUFFEL, of Dorpat, said in regard to intestinal obstruction, when a loop of intestine a certain length becomes strangulated, the phenomena are somewhat different. It is not that part of the intestine situated immediately above the strangulated loop which distends itself; it is the loop itself, and its distention alone produces meteorism. There is another particularity which allows the diagnosis of strangulation of a large loop. In ordinary cases the intestine presents very pronounced peristaltic movements in the parts situated before the obstacle and which are in a distended condition; this, however, does not take place in the case to which he referred. The strangulated and distended loops present no peristaltic motion. In such cases laparotomy is preferable to enterotomy, which is practicable only if the occlusion is not too high up.

DR. STENZEL, of Dresden, had seen two patients who suffered from gastric ulcer, in whom the ulcer terminated in perforation. He operated; the ulcer was excised and sutured. Although these two cases terminated fatally, he thought that laparotomy is necessary in such cases, and that our incision must be made as large as possible.

PROF. MIKULICZ said that simple intestinal obstruction can be diagnosticated from intestinal strangulation by the fact that in occlusion the urine contains much indican; in strangulation only do we find albuminuria.

DR. LESER, of Halle, in a paper on

PRIMITIVE ACTINOMYCOSIS OF THE SKIN.

The usual seat for the development of actinomycosis is in some part of the respiratory or intestinal tract, yet he had observed three patients in whom the parasite of actinomycosis developed in the skin, without there being any other localization of the disease. In the first patient a great number of cutaneous ulcerations could be seen which resembled tuberculous lesions; yet from the depth of the ulceration one could find a thick cord which penetrated through the muscles to the bones; and, on the other hand, there was no adenitis. He had on several occasions curetted the ulcerations by penetrating as deeply as possible, and he cauterized freely; the disease recurred several times, but the patient was finally cured. The second patient appeared to have had acute septicæmia. The third resembled very much the first case. On microscopical examination of the matter from the ulcer one could find very easily the radiated fungi of actinomycosis, yet the balls were not quite round, but oval. The absence of ganglionic involvement and the presence of a cord extending down into the deep parts are of very great diagnostic importance.

DR. ROSTER, of Munich, did not think that such a form of actinomycosis is very rare; there are numerous examples of it in the scientific reports. In nearly all such cases the actinomycosis had developed on operative or traumatic wounds.

DR. KITASATO, of Tokio, Japan, read a paper on

PURE CULTURES OF NICOLAÏER'S TETANIC BACILLUS.

The first description of the bacillus of tetanus is due to Nicolaïer; it has been found in the ground, in the tetanic man, and pure cultures of this bacillus have never been obtained until now. A young soldier died from tetanus; in the pus obtained from his wound the bacillus of Nicolaïer was found. The inoculation of this pus in mice determined the appearance of true tetanus, and in those animals the characteristic bacillus has been discovered; but the cultures always failed, and only mixed cultures could be obtained. Studying these more closely, he found, beside Nicolaïer's bacillus, three species of facultative anaërobic microbes and seven species of facultative aërobic microbes, but none of them could produce tetanus. The tetanic bacillus is a true anaërobic bacillus. After having seen that the mixed culture obtained with the tetanic bacillus contains the greatest number of Nicolaïer's bacilli when it is maintained at a temperature of 97° F., he subjected it for some time to this temperature, and the culture being then in full development, he placed it in a water bath at 176° F. This temperature

kills all adventitious microbes, but allows the tetanic bacillus spore to live. After this partial sterilization, the plate culture is maintained at a temperature of 64° to 70° F., in an atmosphere of hydrogen. In this manner he succeeded in obtaining a pure culture of Nicolaïer's bacillus, with which he was enabled to produce tetanus in rats, guinea-pigs, and mice. The tetanus always propagates itself from the point of inoculation; the regions surrounding this point are always first affected. Nicolaïer's bacillus resists heat very well, and must be exposed for five minutes to a temperature of 212° F. to be killed. A five per cent. solution of carbolic acid does not destroy this bacillus in ten minutes. The most curious fact, however, is, that the bacilli disappear very rapidly in the blood; they apparently produce ptomaines, but this remains to be demonstrated.

DR. HOFFA, of Wurzburg, read a paper on

A NEW PTOMAINE.

Septic infection must be separated from septic intoxication. When we find numerous microörganisms in the blood, we may speak of septic infection, but in other microbian diseases the contrary is the rule; we do not find many microbes, these are very rare, and it is an exception if they are found. In those cases in which bacteria rapidly disappear from the organism, we naturally ask how is this accomplished? They kill by the ptomaines which they produce. He had poisoned a rabbit with bacilli from mice septicæmia, renewing Briéger's experiments, and after having killed it, and ligatured and extirpated the whole urogenital canal, as well as the digestive canal, so as not to extract septic products from these organs, he cut up the remaining rabbit into very small pieces, and worked the resulting mass according to Briéger's method. He isolated in that manner a base, methylguanidine ($C_2H_7N_3$), which is the same poison obtained by Briéger and Bochlisch with bacilli from Finckler-Prior. As methylguanidine is produced by oxidation of the creatine, he submitted to the same chemical analysis a healthy rabbit, who was sacrificed in the same manner as the rabbit killed by the bacilli. He found no trace of methylguanidine. This base is a very violent poison, and one-thirty-second of a grain is sufficient to kill a rabbit. It is this methylguanidine which is produced by the bacilli of the septicæmia of mice, and which kills those animals. Of the bacillus obtained from the spleen he had also isolated a toxic base, the formula of which is $C_3H_6N_2$, which is a different body from methylguanidine.

DR. CORNET, of Reichenhall, then spoke on

INOCULATION OF TUBERCULOSIS ON HEALTHY MUCOUS MEMBRANES.

He had inoculated in dogs Koch's bacillus, so as to be able to study the mechanism of infection which produces tubercular or scrofulous adenitis in man. His experiments had shown that the ganglia of the region through which the virus had penetrated are always involved first; this explains the frequency of tubercular cervical adenitis in man. The parts which surround the neck, the nasal and buccal mucous membranes, the ocular conjunctiva, and the ear, are favorable places for the penetration of the pathogenic germs into the tissues. The ganglia of the side corresponding to the infection are involved first, after which the glands of the opposite side are infected. His inoculations have given him positive results, not only when he had to deal with a spontaneously or artificially ulcerated mucous membrane, but even when he inoculated by simple friction on an intact mucous membrane.

(To to continued.)

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, June 6, 1889.

THE PRESIDENT, ALFRED L. LOOMIS, M. D., IN THE CHAIR.

DR. PRINCE A. MORROW read a paper on

PERSONAL OBSERVATIONS OF LEPROSY IN MEXICO AND THE SANDWICH ISLANDS, WITH MAGIC LANTERN ILLUSTRATIONS OF TYPICAL CASES.

He said that leprosy was too often looked upon as possessing only a historic interest, like the plague and other diseases of former times. Unfortunately, however, it could not with reason be so regarded. It was a living reality, and a map representing its geographical distribution showed that it extended over fully one-third the surface of the globe. This general distribution of the disease had, he believed, a very important bearing upon its etiology. It was impossible to give the exact number of lepers at present in the world, but in India alone there was fully 150,000. In Africa and South America it also prevailed extensively, and in Brazil there were said to be from 5000 to 10,000 cases.

The importation of leprosy from a country where the disease was endemic to one where it had previously been unknown, could always be traced to the agency of personal contact. In Central and South America it had been introduced by Portuguese traders, in Mexico by the Spaniards, in Canada by the French; and in Canada there were at the present day three distinct centres of the disease. In our own country, the leprosy met with could be traced to three or four separate sources. In Louisiana it had been introduced by the Acadians after their settlement there in 1758. In Iowa, Wisconsin, Minnesota, and Illinois, it had been introduced by Scandinavian immigrants; and in California and Oregon, by the Chinese. Quite a number of cases had also been met with in Charleston, S. C., and at Key West. Dr. Geddings had personally seen about 20 in Charleston. Dr. Morrow said that he had recently become acquainted with the hitherto unknown existence of the disease in Utah. He saw cases at Great Salt Lake City, and ascertained that it was introduced by natives of the Sandwich Islands who had been brought there by the Mormons.

His own personal observations began in New Orleans, where Dr. Blanc reported the existence of 42 cases last year, these being entirely independent of the lepers of the Teche River district of Louisiana. At various points along the line of the Southern Pacific Railway he also found the disease. In Mexico leprosy has existed ever since the time of Cortez, who established a lazaretto for the subjects of it. This continued in use until about thirty years ago, when it was abandoned; and since that time the cases have been cared for in the general hospitals, no attempt whatever to isolate them being made. Numbers of these people may be met

with in the streets of Mexico at any time. At San Francisco he saw quite a number of cases, six of them being in the pest-house there.

The Sandwich Islands probably offered the best field in the world for the study of leprosy, on account of the comparatively recent origin and the great prevalence of the disease there. We can trace there the influence of certain factors, such as race, climate, environment, etc. Segregation has been secured by the establishment of an isolated leper settlement, and there are now more than 11,000 cases at Morlachi.

It has been regarded as a reproach upon medical science, that so little should really be known of a disease which has existed for so long a time and extended so widely; but it is only within the last twenty-five years that the true character of leprosy has been ascertained. We now know that it is a parasitic disease, and the lepræ bacillus, discovered about the year 1870, by Hansen, presents certain analogies to the tubercle bacillus. This is particularly true as regards its remarkable vital tenacity. Like all specific microbes, it has an elective affinity for certain fluids and tissues of the body. It is met with especially in the mucous membranes, the lymph glands, the liver, the spleen, the testicles, and the connective tissue of the peripheral nerves. It is absent from the blood, the urine, and the physiological secretions, though it is well known that when the lesions of the mucous membrane of the nose break down it is abundant in the nasal secretion. It has been questioned whether it is found in the pathological secretions, but there can be no doubt that it abounds in the vaccinal fluid.

As regards the origin of leprosy, it can be stated positively that the disease never originates spontaneously. It does not attach to the soil, water, or food, but is always communicated from one individual to another, and can always be traced to personal contact. Its period of incubation is a long one. This is variously stated as from three to five years, but in certain instances seems to be from ten to fifteen years. It is a very difficult matter to arrive at the exact period of incubation, because there is no initial lesion and the prodromal symptoms are very indefinite. The progress of the disease is slow, but it almost invariably terminates fatally.

There are certain moot points in regard to the disease, and the first one is as to its contagiousness. This has never been at all questioned until comparatively recent times; but about thirty years ago it began to be doubted. In 1867 the Royal College of Physicians of London made the public declaration that leprosy is not contagious. Ten years ago it is probable that the majority of the medical profession did not accept contagiousness, and so recently as 1885, when the subject was under discussion, there were only three men in the French Academy of Medicine who upheld the doctrine of its contagiousness. When the matter was brought up again in 1888, however, it was proved that quite a number of the leading authorities had accepted this. It is worthy of note that the leading dermatologists of New York have never given assent to the heresy of the non-contagiousness of leprosy.

The history of the disease in the Sandwich Islands affords the most conclusive proof of its contagiousness. In no other way can the rapid spread of the disease throughout the race be accounted for; and at the present day from 5 to 10 per cent. of the native population may be considered lepers. In investigating the disease there one can get at a history of personal exposure in almost every instance. At the leper settlement many of the patients are incapacitated from taking care of themselves, and have to have relatives or friends to look after them who are personally free from the disease when they go there. It has been observed that a very large number of these attendants after a time contract the disease; and the official reports show that out of sixty-six such individuals who were free from leprosy in 1888 twenty-three were found to have it when the next visit was made to the settlement later. Again, it is a well-known fact that a considerable number of foreigners who have lived in the Sandwich Islands have contracted leprosy.

As to the modes of infection, our knowledge is not positive, but in a large number of cases this is probably by sexual intercourse. It seems probable that the disease may be contracted through abrasions of the mucous membrane or skin, and also by means of animal parasites or the bites of mosquitoes and other insects. In the Samoan Islands elephantiasis Arabum has attained a more marked development than in any other part of the world, while elephantiasis Græcorum is unknown; and in the Sandwich Islands, where the latter is so prevalent, elephantiasis Arabum is unknown. In Mexico, however, both forms of the disease are found. In the Sandwich Islands vaccination has undoubtedly been one of the causes of the spread of leprosy, humanized virus being used, and no distinction being made between healthy and unhealthy subjects in procuring the virus. Inoculation of leprosy has been successfully practised in one instance, the subject being a condemned criminal. Dr. Morrow said he had seen one case in which the patient claimed to have contracted the disease from the bite of a leper, and another in which the patient stated that it came from the prick of a pin with which a leprous boy had amused himself by sticking it into his body.

Another moot question is that of heredity. Formerly this was regarded as positively established, and in all ages it has been regarded as the principal cause of the disease. In his personal observations, however, Dr. Morrow said that he found no proof whatever to support the view of heredity. A predisposition to leprosy might be transmitted, as in the case of tuberculosis; but he did not believe that the actual germs of the disease are ever so transmitted. There is not a single case of congenital leprosy on record. In instances of suspected heredity, the child never shows evidences of the disease under the age of three years, and usually not until puberty. In general, the disease develops only in those from thirty to fifty years old. Leprosy, then, is either analogous to late syphilis, or else it is not transmitted at all to offspring. Observation shows that the children of lepers do not become infected unless they are kept in close contact with their parents. Very few living children are born in the lepers' settlement. For some years there were only two; and of twenty-six infants that lived, the report of 1866 shows that nine presented evidences of the disease between the ages of three and fourteen years, while the remainder had continued absolutely exempt from it. It is altogether probable, therefore, that in all cases of suspected heredity the disease is really due to post-natal contagion.

Dr. Morrow then gave an exhibition upon the screen

of a large number of photographs which he had collected in the Sandwich Islands, and in connection with these referred to the different forms of leprosy, and gave a sketch of its clinical history. Among the photographs was one of the late Father Damien, taken only six weeks before his death, and one of the convicts upon whom inoculation was successfully practised—the only case on record. This man, who had been condemned to death, was given his choice between execution and imprisonment for life with inoculation with leprosy. With the criminal's written permission, Dr. Arning inoculated him in September, 1884. Bacilli were found in numbers about the inoculated spot until March, 1885, after which they gradually diminished in number. For several years the result was regarded as negative; but more recently, evidences of infection have developed, and at the present day there can be no question of his having well-marked leprosy.

As to the practical danger of the spread of leprosy in this country he believed that such a danger undoubtedly exists. He said that the disease in its present state here might be compared to a conflagration which could easily be extinguished at first, but which, left to itself until it had gained a certain headway, could not be subdued until after all the material it had to feed upon had become exhausted. In the Sandwich Islands, in 1848, there were but few cases of leprosy, and for twenty years the Government paid no attention to the disease. By that time there were about 250 cases, and the authorities, becoming alarmed, took stringent measures for its repression. A system of segregation was adopted, but, unfortunately, the danger was appreciated too late. Dr. Morrow said he did not believe that a calamity such as had overtaken the Hawaiians was in store for this country; but, at the same time, he thought there was a sufficiency of leprous seed here to stock this or any other country. The only question was whether the soil was favorable for the development of the disease. Any one who believes in the contagiousness of leprosy must assume either that a great danger menaces us, or else that the conditions of our civilization are not favorable for the spread of leprosy.

Dr. Morrow said that in his opinion the danger was not such as seriously menaced the public health, as the disease would spread very slowly, if at all. At the same time it should be borne in mind that leprosy is a disease in which the resources of medical science prove altogether futile, and measures should, therefore, be taken to stamp it out. It is probable that there are more cases in this country now than ever before. The report of 42 cases in New Orleans last year was a surprise to every one, and the propriety of legislative enactment for the suppression of the disease is unquestionable.

DISCUSSION ON THE DANGERS TO BE FEARED FROM THE SPREAD OF LEPROSY IN THE UNITED STATES.

DR. C. W. ALLEN said that his convictions on this question were very decided. Two years ago, in a paper read before the Medical Society of the County of New York, he had contended that lepers should not be admitted into this country, and that those already here should be segregated. There were at the present time, as has been stated by Dr. Morrow, many more lepers in the United States than ever before. Two years ago he had placed the number at 250. This number, he had reason to believe, was too small at that time, and he thought there could be no doubt that there had been a considerable increase since then. When we considered the large number of cases all about us, and the increased likelihood of the spread of the disease from the increasing facilities of modern travel, etc., this question became one that we could no longer shut our eyes to. It was true that thus far very few cases had developed here (almost all being imported from other countries), yet some instances had been reported by Dr. Bulkley and others. Of the 42 cases reported in New Orleans, where no leprosy was supposed to exist, 29 were natives of Louisiana, and 22 of the city of New Orleans. One of these had been a nurse in a hospital where a leper was under treatment for some time. The evidences of the contagiousness of the disease were positive, and as long as a single leper existed anywhere he would constitute a source of danger to those about him.

DR. L. DUNCAN BULKLEY said he regarded this as one of the most important questions ever brought before the Academy. He thought no one could fail to see that whenever leprosy has been allowed free scope it has spread; while, on the other hand, whenever proper measures have been taken in time against its spread, it has been exterminated. There seemed to him a propriety in having the matter agitated, and he thought the least the health authorities could do would be to ascertain the number and condition of the lepers now in this country. He also thought it would be well for the Academy to further discuss the question of the possible spread of the disease and the best means of preventing this. About twenty years ago he saw in the New York Hospital a very bad case of leprosy. There was no cause for it, so far as he knew, and the patient was a man of cleanly habits. Since then he had seen two or three cases every year in New York. He had met with one case in a patient who had never been many miles from Poughkeepsie, where he lived, and another in one who had never been far away from New York. Precisely how they contracted the disease he did not know, but there could be no question that they had derived it from antecedent cases. Leprosy always comes from leprosy. He differed from Dr. Morrow, however, in the opinion that the bacillus lepræ does not exist in soil, water, etc., and believed that it may be left there, like other disease germs. In conclusion, he said he thought it well to appoint a committee to report on the question under discussion at some future time.

DR. GEORGE H. FOX said that the exciting of alarm seemed to him objectionable on account of the false assumption that there has been a spread of leprosy in this country. The cases met with here were nearly all imported, and in spite of the fact that there was no law prohibiting the entrance of lepers, and that no segregation was practised, he believed that the number was at present undoubtedly smaller than at other periods. Some of the cases formerly here had died, and others had left the country. He also knew of one case at least in which the patient considered himself cured; no signs of the disease having appeared for six years. He admitted that there was a slight danger from the lepers still remaining here; but so there was, he said, from hydrophobia. As a rule, the whites of the Sandwich Islands were free from leprosy, and he had yet to learn of an instance of

the spread of the disease in a white civilized country. Its prevalence among the Hawaiians, he believed, was in great part attributable to their uncleanly habits and mode of living. The danger was, of course, greater, the greater the number of lepers; but it was very rare for nurses, sisters of charity, and others in constant attendance upon leprous patients, to contract the disease. All lepers, he thought, should be prevented from landing here, as the paupers were, not so much from the likelihood of their spreading the disease, as because, like paupers, they would be a burden on the community. The popular dread of this disease was unfounded and absurd, and even physicians shuddered at the name of leprosy, while they looked with complacency upon syphilis and tuberculosis.

Dr. H. G. Piffard said that ten years ago he had read a paper before the Academy in which he discussed the question raised to-night. The points for which he contended at that time were, *first*, the contagiousness of the disease; *second*, the segregation of lepers; *third*, that it was the function of the National Government to attend to the matter. Since then his views had not altered. At that meeting a committee was appointed from the Academy to investigate the subject of leprosy in this country, and the committee so appointed performed the work required of it so far as it was possible to do so. It did not succeed, however, in tracing out more than forty or fifty cases in the United States. Many cases unquestionably escaped observation, and there was no doubt in his mind that at the present time there are at least five times as many lepers in the country as there were then. That segregation was necessary was shown by the fact that wherever this has not been practised the disease has increased, not in arithmetical, but geometrical progression. To the question, Whose charge is it to attend to this segregation? he would answer, The National Government. The Government should, in the first place, prevent the entrance of all lepers into the country; and, secondly, induce, as far as possible, all lepers now here to go to properly-appointed lazarettos. It should be the duty of each State to place its own lepers in these lazarettos.

Whether this discussion could have any practical effect he doubted very much. Not until the necessity of taking active measures to prevent the spread of leprosy forced itself upon public attention would anything be done, but that time, he believed, would surely come sooner or later.

Dr. F. R. Sturgis said that he believed that Dr. Morrow was right in stating that there was no immediate danger to the public health from this source, but that it was undoubtedly the duty of the medical profession to call attention to the matter. Up to the present time the evidence of direct inoculation with leprosy had been lacking; but the case of the criminal referred to by Dr. Morrow really seemed to show the possibility of inoculation and further confirm the contagiousness of the disease. It was probable that leprosy followed a course similar to that of syphilis; being more contagious in its earlier than its later stages. As to the bacillus mentioned, he did not think it had been as yet proved to be the cause of the disease, any more than was the case in regard to the so-called bacillus of syphilis. Dr. Fox depended on negative evidence for the position which he assumed; but one positive case was of greater value than all such negative evidence. In our crowded and filthy lodging-houses he believed that there existed all the conditions favorable to the development of leprosy if the contagion was once introduced. As to the comparative risk from leprosy over syphilis, he said he would rather run his chances with the latter, as there was, so far as he knew, no cure for leprosy. Syphilis might be ten times more contagious than leprosy, but leprosy was ten times as dangerous.

Dr. Robert W. Taylor said that every year he saw from one to three cases of leprosy, principally at Charity Hospital. He believed the danger of serious trouble from the disease was remote, and he was therefore inclined to take a more hopeful view of the future than some of the speakers.

Dr. Morrow, in closing the discussion, said there seemed to him but little doubt that the leprosy in the case of the criminal mentioned was positively caused by the inoculation. This was made in 1884, and the four years that elapsed before leprosy made its appearance corresponded entirely with the ordinary incubation period of the disease. It was an important fact, he thought, that the spread of leprosy in the Sandwich Islands had occurred under conditions of high civilization, the state of the population being greatly superior to what it was fifty years before. Dr. Fox labored under a misapprehension in regard to the people there, who are in reality infinitely better off than the great majority of the poorer classes in this country. For one thing, they are very cleanly in their habits and are accustomed to bathe four or five times a day. Yet, notwithstanding their improved condition, the scourge of leprosy had attained the most fearful proportions among them.

In regard to the contagiousness of leprosy, there was one point which offered a possible explanation of the difference of opinion which had existed concerning it. He thought it extremely doubtful if the anæsthetic type of leprosy was capable of transmitting the disease. It was this form, rather than the tubercular, which predominated in India and in Mexico to-day, and in this the bacilli are not found in the external lesions. To his mind the evidences of contagiousness abounded and superabounded. He did not wish to be considered an alarmist, but in regard to this disease he believed that a wholesome dread was better than a false security. By the adoption of active measures he thought it could be stamped out absolutely.

At the conclusion of his remarks Dr. Morrow exhibited under the microscope specimens of the bacillus lepræ which had retained their vitality for a very long period.

NEW INVENTIONS.

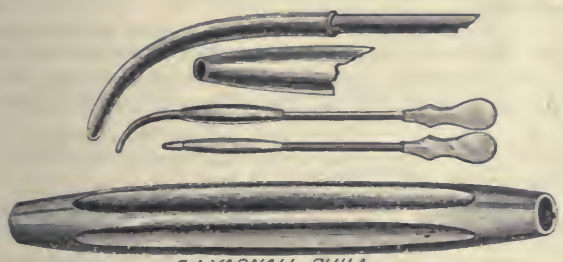
GROOVED BOUGIES FOR APPLYING OINTMENT TO THE URETHRA AND INTERIOR OF THE UTERUS.

By J. NEELY RHOADS, M.D.,
CHIEF OF CHILDREN'S CLINIC, JEFFERSON MEDICAL COLLEGE HOSPITAL, PHILADELPHIA.

For the past two or three years I have been using different ointments on bougies in the treatment of gonorrhœa of long standing and chronic urethritis. The results obtained were generally negative, owing, I think, to inadequate instruments, for the contraction of the

meatus renders it next to impossible to reach the desired parts with the salve on the ordinary bougie or sound, the salve remaining in a large ring around the bougie at the handle upon withdrawal. And the cupped sound contains such a small number of cavities and are arranged so that the urethra is only touched with the ointment in spots in a haphazard way, and being made larger at the handle than at the cupped portion, gives so much pain, due to stretching of the meatus, that it must be withdrawn before the parts are properly reached or the salve dissolved. The ribbed bougie and catheter are subject to the same meatus-stretching objection. The syringe in use for carrying ointment is very inaccurate in its application, and is not, precisely speaking, an ointment-carrier, as ointments must be semiliquid or they cannot be used.

Last fall I had several three-inch bulbs made, such as are used in my pocket-set,[1] deeply grooved on four sides, as shown full size in accompanying cut, and have used



them since with gratifying results. I gave several sets of these to my friends, who speak of them very highly, reporting cases of urethritis cured or benefited, both acute and chronic, specific and non-specific, occurring in both sexes. Several cases of cervical endometritis are also being treated by this method.

I have cured several cases of chronic gonorrhœa of long standing in the male by applying the following ointment to the grooved bulbs:

℞.—Argenti nitratis	gr. x.	
Tr. benzoin comp. . . .	gtt. xv.	
Unguenti petrolii . . .	℥j.	—M.

Making two or three applications per week. After applying the salve I insert the bougie in the ordinary manner, using either the straight or the curved point—preferably the straight. After the bulb passes the meatus I watch the patient's face, ascertaining by the facial expressions which are the most sensitive parts, and then allowing the instrument to remain in such a position that they shall be perfectly anointed.

Now the advantage claimed for this instrument over other ointment-carriers is the operator's ability to locate by it the exact sensitive or diseased spot of the urethra, for, be it remembered, after the bulb of this instrument passes the meatus (the most sensitive part of the normal urethra) the passage is painless if the urethra be not inflamed; hence, the moment the patient flinches we know beyond a doubt that we have reached the diseased part. I have frequently allowed a bulbous bougie of large size to remain in position for ten and even fifteen minutes, the patient walking around my office perfectly unconcerned. We do not expect this instrument to cure every urethritic or endometritic disease, but do hope it will find a useful place as a salve-carrier.

NEWS ITEMS.

Proposed Amendments to the Constitution of the American Medical Association.—The following proposed amendments will come up for action at the Newport meeting of the Association.

Amendment proposed by Dr. N. S. Davis, of Chicago:

"The General Committee shall be composed of two members from each State and Territorial Medical Society entitled to representation by delegates in the Association, and from the Medical Departments of the U. S. Army, Navy, and Marine-Hospital Service. They shall be chosen by the members registered and present at each annual meeting from each State and Territory, and from the Medical Corps of the U. S. Army, Navy, and Marine-Hospital Service, acting separately, on the third day of each annual meeting; each delegation reporting the names of the members chosen to the Permanent Secretary of the Association on the same day, that they may be announced by him at the opening of the morning session of the fourth day. At the first election each delegation shall choose two members of the General Committee, one of whom shall serve one year, and the other two years, and at each annual election thereafter one member shall be chosen to serve for two years, thus making the term of office of members of the General Committee two years. It shall be the duty of the General Committee thus constituted, to organize by choosing annually a Chairman and Secretary, and such sub-committees as may be found necessary to facilitate the work that may be assigned to it; to meet annually at the place and on the day preceding each annual meeting of the Association, and as often during that week as may be necessary; to nominate, on the third day of each annual meeting, all the general officers of the Assocation (none of whom shall be members of its own body), the members of the Committee of Arrangements, the Committee on Necrology, seven members of the Judicial Council, and three members of the Board of Trustees for Publication, for election by the Association; to recommend the place and time of holding the next annual meeting; and to consider and report upon all subjects that may be referred to it by vote of the Association. The presence of one-third of the whole number of members elected to the General Committee shall constitute a quorum for the transaction of business. If, at any annual meeting of the Association, it shall be found at the close of the general meeting of the first day that a quorum of the General Committee is not present, it shall be the duty of the President and Permanent Secretary to fill the vacancies in the Committee temporarily, by selections from the lists of delegates registered as present from the States to which the vacancies belong."

Should this provision be adopted by the Association, the Permanent Secretary should be authorized to substitute the name "General Committee," "for Nominating Committee," wherever the latter occurs in other parts of the Constitution and By-Laws.

Amendment offered by Dr. J. M. Keller, of Arkansas:

"To change the By-Law whereby the officers of the Sections are elected by the Sections."

Amendment offered by Dr. N. S. Davis:

"Strike out the last clause of paragraph VII., relating to individually affixing names to the Constitution and Regulations of this Association."

Amendments offered by Dr. H. N. Moyer, of Illinois:

"There shall be created a Section of Pharmacy and Materia Medica, which shall have its own autonomy, in like manner as the Section in Dental and Oral Surgery. Reputable members of the State Pharmaceutical Associations shall be eligible as members of the same on presentation of credentials from their State Secretary, but shall have no voice in the general sessions of the Association.

"The Section of Surgery shall hereafter be denominated the Section of Surgery and Gynecology.

"There shall be created a Section of Anatomy and Physiology.

"The Section of Obstetrics and Diseases of Women shall be abolished.

"The Section of Diseases of Children shall hereafter be denominated the Section of Obstetrics and Pædiatrics.

"The Section of Dermatology and Syphilography shall hereafter be denominated the Section of Dermatology and Genito-urinary Diseases.

"The Section of Medical Jurisprudence shall hereafter be denominated the Section of Mental and Nervous Diseases.

"The Section of State Medicine shall hereafter be denominated the Section of State Medicine and Medical Jurisprudence.

"The Section of Practice of Medicine, Materia Medica, and Physiology shall hereafter be denominated the Section of Internal Medicine."

Cigarette Selling in New York.—The smoking of cigarettes by boys is likely to undergo a wholesome restriction in the State of New York. The *New York Medical Journal* of June 8, 1889, tells of a law having been enacted by the last Legislature, making it a misdemeanor for dealers to sell cigarettes or any form of tobacco to persons under sixteen years of age. A police order was promulgated on May 31st, giving effect to this enactment.

Leprosy in Russia.—Leprosy, says the *Provincial Med. Journal*, June 1, 1889, is on the increase in Russia. During the last ten years forty-nine patients were treated in the St. Petersburg hospitals, half of whom were natives of the city. The Baltic provinces suffer most from the disease.

Corrigendum.

In foot-note, page 630, *for* "alcoholic tincture of benzine," *read* "tincture of benzoin."

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY, FOR THE WEEK ENDING JUNE 15, 1889.

NORTON, O. D., *Assistant Surgeon.*—Ordered to the Naval Hospital, Chelsea, Massachusetts.

HALL, J. H., *Passed Assistant Surgeon.*—Detached from the Naval Hospital, Washington, D. C., and granted six months' leave to go abroad.

LEWIS, D. O., *Passed Assistant Surgeon.*—Detached from the Naval Academy, and ordered to the Hospital, Washington, D. C.

BRIGHT, GEORGE A., *Surgeon.*—Detached from the Navy Yard, Norfolk, Va., and wait orders.

MARMION, R. A., *Surgeon.*—Detached from the Receiving-ship "Franklin," and ordered to the Navy Yard, Norfolk.

BERTOLETTE, D. N., *Surgeon.*—Ordered to the Receiving-ship "Franklin."

KIDDER, B. H., *Medical Inspector.*—Ordered to the Naval Academy, Annapolis, Maryland.

WALTON, T. C., *Medical Inspector.*—Detached from the Naval Academy, and ordered to the U. S. S. "Chicago."

BEVER, H. G., *Passed Assistant Surgeon.*—Ordered to the Training-ship "Portsmouth."

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 11 TO JUNE 18, 1889.

By directions of the Acting Secretary of War, the following changes in the stations of officers of the Medical Department are ordered:

HARTSUFF, ALBERT, *Major and Surgeon.*—Is relieved from duty at Fort Hamilton, New York, and ordered to Fort Omaha, Nebraska.

BROWN, J. M., *Major and Surgeon.*—Relieved from duty at Fort Omaha, Nebraska, and ordered to Fort Meade, Dakota.

SHANNON, W. C., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Meade, Dakota, and ordered to Fort Yates, Dakota.

IVES, FRANCIS J., *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Fort D. A. Russell, Wyoming, and ordered to Fort Lyon, Colorado.

PHILIPS, J. L., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Lyon, Colorado, and ordered to Fort Crawford, Colorado.

MCCAW, WALTER D., *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Fort Crawford, Colorado, and ordered to Fort McPherson, Atlanta, Georgia.—Par. 9, *S. O. 136, A. G. O., Washington, D. C.*, June 13, 1889.

GANDY, CHARLES M., *Captain and Assistant Surgeon.*—Upon the abandonment of the post of Fort Concho, Texas, will report in person to the commanding officer at Fort Clark, Texas, for duty at that station, to relieve Ogden Rafferty, First Lieutenant and Assistant Surgeon, reporting also by letter to the commanding general Department of Texas. Lieutenant Rafferty, on being relieved by Captain Gandy, will report for duty to the commanding officer San Antonio, Texas, reporting also by letter to the commanding general Department of Texas.—Par. 7, *S. O. 133, A. G. O., Washington*, June 10, 1889.

GIBSON, ROBERT J., *Captain and Assistant Surgeon* (Fort Trumbull, Conn.).—Is designated as Medical Officer for the encampment at Fisher's Island, New York, and he will proceed to Fisher's Island, New York, August 1, 1889, and will report to the commanding officer for duty at that post.—Par. 5, *S. O. 133, Headquarters Division of the Atlantic*, June 13, 1889.

By direction of the Acting Secretary of War, PHILIP G. WALES, *First Lieutenant and Assistant Surgeon* (recently appointed), will proceed from this city to the Presidio of San Francisco, California, and report for duty to the commanding officer of that post, reporting also by letter to the commanding general Division of the Pacific and Department of California.—Par. 3, *S. O. 132, A. G. O.*, June 8, 1889.

TEN EYCK, BENJAMIN L., *First Lieutenant and Assistant Surgeon* (recently appointed).—Will proceed from New York City to Fort Leavenworth, Kansas, and report for duty to the commanding officer of that post.—Par. 2, *S. O. 138, A. G. O., Washington, D. C.*, June 15, 1889.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

VOL. LIV. SATURDAY, JUNE 29, 1889. NO. 26.

AMERICAN MEDICAL ASSOCIATION.

FORTIETH ANNUAL MEETING, NEWPORT, 1889.

THE PRESIDENT'S ADDRESS.

Delivered June 25th.

BY W. W. DAWSON, M.D.,
OF CINCINNATI.

THE Premier, Mr. Gladstone, after quoting the statistician who estimates the English-speaking people at the close of the next century at one thousand millions, says, "What a prospect is that of many millions of people, certainly among the most manful and energetic in the world, occupying one great continent." This destiny in numbers is startling, but the assertion of Dr. Döllinger, a German scholar, portrays the culture of the future almost as strikingly when he says that "the intellectual primacy of the whole world is certain to fall to the Anglo-Saxon race." Most of that race will be in America.

Looking to such a future the position of the learned professions is certainly conspicuous—their obligations imperious. Medical men should be loyal to this grand destiny.

An eminent modern critic, in discussing civilization in America, while admitting that we have well solved the political and social problems, asks what have we done to solve the human problem, "the humanization of man in society." The struggle in his own country, he asserts, has resulted in "an upper class materialized, a middle class vulgarized, and a lower class brutalized."

We trust that our efforts have yielded better fruit; and since medical science and medical men are prominent factors in society among every people, we may well ask what they have accomplished, what part they have here taken in the solution of the vital problem. In the *Century of American Medicine*, Prof. E. H. Clarke, in his essay, says:

"It is not an extravagant assertion to say, that in all this turmoil, change, and progress (referring to the revolutions and changes in society, religion, and governments for the past century), medicine has kept abreast of the other natural sciences, of politics, and of theology, and has made equal conquest over authority, error, and tradition," and it may be added, has contributed largely to man's comfort, happiness, and advancement. To intensify this, reference need only be made to some of our triumphs—to vaccination, to anæsthesia, to sanitation, the prevention of pestilence, the lengthening of human life. It is, however, more especially the contributions of the profession in America to which attention is desired at this time. What are we doing in the humanization of man, in the work of civilization?

Are our medical practitioners and our medical teachers what they should be? We shall see. Criticisms abound concerning the defects of medical education. Those who do not condemn, often ridicule; these criticisms and strictures are made for the most part, it must be said, by gentlemen unacquainted with teaching, without any practical knowledge of the constitution of medical colleges, or of the toil, devotion, and sacrifice made necessary by those engaged in didactic and clinical instruction.

These censorious addresses are delivered before and to a body of professional gentlemen, the peers of any, some of whom have grown gray in the hard service, others are still in the prime of life, with reputations coextensive with civilization. The rest are young, full of life and enthusiasm, fired with ambition to render loyal service to that profession which they have chosen. Can our system be so defective? The pessimistic orator seems to forget that he is the product of the system of medical education which he is so severely condemning. Some one has said, "By retrospection and introspection an individual, like a profession, may be benefited." In this self-examination we should have but one motive—the elimination of error, the development and support of truth.

Education cannot make all great or equal. It tends, however, to make all safe. In the crucible of private, practical life, evolution asserts itself, and the fittest survive.

In making a retrospect of our profession it may be well to look for a moment at medical teaching in this country.

The way is long between Aristotle and Bichat, and Buckle says that he found no middle-man in this long period; it is darker than it is long. During all this time medicine was not taught legitimately. The renaissance, if it may be so called, began with Hunter and Bichat. No real progress, however, could be made while oxygen remained locked in the silent embrace of all organic and inorganic nature. Priestley, escaping from the religious and political contests, and it may be persecutions, of the old world, came to this country to demonstrate his great phlogiston, oxygen.

Bichat and Hunter restored the proper study of medicine. They represent the turning-point from idealism, speculation, and theory to accurate and close observation. The latter, John Hunter, in 1767 was lecturing and taking students into his own house, and it is curious to know that here, in far-off America, Shippen and his contemporaries in Philadelphia and New York, about the same time or very soon after, began teaching medicine and surgery upon essentially the same plan. Of these men, one who so recently passed away that you can almost hear the sound of his voice and feel his magnetic presence, when speaking of the men who lived at the close of the last and during the early part of this century, said, and justly said, "Not a few of them were the worthy peers of Roux, Abernethy, Crampton, Bell, de Graaf, and Scarpa."

To quote again:

"During the past century, medicine has been enfranchised from superstition, *quasi*-charlatanism, bold empiricism, and speculation, and has developed into a symmetrical science, affiliated with the other natural sciences, studied by the same methods and by the same appliances as they are, and, like them, has been planted upon the solid basis of fact and demonstration."

It may be profitable for us to inquire and determine what part the profession in America has taken in placing medicine upon the high ground which it occupies. What have we done, what are we doing, and what forecast can we make of the future?

At the close of the eighteenth century, Boerhaave declared that all that had been learned up to that time was comprised in three propositions: "Keep the head cool, the feet warm, the bowels open." All other pages in the volume which he left were blanks. Many pages, however, it will not be denied, have been filled during the present century. What have been our contributions? Have they been such as to rank us with the acknowledged conservators of mankind?

In giving attention to this subject, let us for a moment reflect upon the peculiar position of the profession and of medical teaching in this country. For many years (and even now), with few exceptions, medical colleges were the creation of the members of the profession, most often of the faculties composing the schools, without endowment,—indeed, it may be said that almost everything on this continent is endowed, except medical colleges,—without governmental aid, depending for their support upon the sacrifice and money on the part of the gentlemen occupying the chairs. Yes, not only without patronage from the government, but society, from some unknown cause, has ever been against legitimate medicine, depending upon the scientific physician in time of trouble, yet, in the interim, openly supporting all sorts of shams, frauds, and impostors.

Elsewhere, college work is provided for by the State; especially laboratory investigations into the nature and the genesis of disease. Hence, it is not strange that in such departments we may not be so far advanced as our European brethren; but, while they have been engaged in experimental studies, we have developed the practical. But everywhere is seen among us an earnest, a burning desire for higher culture, for more exact and accurate knowledge. Especially is this true of our younger members, and of those about entering the profession.

A movement is being made to concentrate those who have had preliminary advantages—those who enter the profession as college-bred. No objection can be urged to this if it be not too exclusive. All efforts, in fact, to refine our profession without emasculating it, should meet with judicious approval.

THE PHYSICIAN OF THE FUTURE.

Whence are medical students to come? What facilities are now afforded, and what does the future promise for the education of our young men, the class from which the medical student, the "coming doctor," is to be selected? The answer to this question will give some comfort, we trust, to the pessimist, and soothe the restless and at times unreasonable critic. And now as to our resources for this work.

By the last census it was shown that nearly four thousand institutions—schools for higher learning—existed in the United States, and that nearly four hundred of them ranked as colleges and universities. In these are massed, yearly, sixty thousand pupils. They, together with two hundred thousand common or primary schools, in the higher grades of which the curriculum nears that of many colleges at home and abroad a third of a century ago, may be looked upon to supply, year after year, a better material from which medical students will be drafted.

Prof. Charles W. Eliot, in his beautiful and forcible Centennial response, enumerated our educational facilities more generously. He painted our future more hopefully when he spoke of the 8,000,000 children in elementary schools, 250,000 in secondary schools, 60,000 in colleges, with 360,000 teachers to train and develop them.

Every one travelling through the States—especially of the West and South, and those situated in the far-away mountains and on the Pacific—must be impressed with the onward march of public instruction, the gradually increasing general intelligence, and the vast sums that are annually expended for the education of the people.

Public school buildings, by their size, adaptation, and attractive surroundings, give an impression which the most sceptical must feel, a promise of the future which cannot be misread. From such as these scientific medicine must reap a share. Every teacher, every one connected with the examination of candidates for the medical degree, knows—and the knowledge is reassuring—that, year after year, the grade of the medical student is advancing, that the material out of which the practitioner is made is constantly growing better, becoming stronger; in other words, that the preliminary education of our students is steadily becoming more broad and comprehensive. I gave utterance to this view a few years ago, in an address which I had the honor of delivering to the State Medical Society of Ohio. Time, I believe, has confirmed what I then said. This confirmation is seen in our graduates as they go forth to take up the line and battle of life. Are they not the equals of the graduates in other professions, in law and theology? As life advances, are they not the peers of any in all the useful elements of true manhood? Are they not the citizens of best rounded characters, citizens most relied upon by their neighbors in foul as well as fair weather?

Again, in addition to facilities already referred to, the most generous provisions are being made, all over our land, for institutions which will be worthy to be called universities. From these graduates will emerge worthy to rank by the side of those bearing the prized degrees from Oxford, Cambridge, Paris, Heidelberg, or Leipsic.

During the summer of 1888, I witnessed the beginning of a university in California, which in scope and equipment will surpass, probably, any school upon the continent. Should Governor Stanford live to develop his conceptions, that far-off State will have an institution of which not only the Pacific Coast, but our entire country, yes, all civilization, will feel justly proud. It may be so liberally endowed that it will command the best abilities of the world.

Of course, upon such an occasion as this, it would hardly be expected that I should, in detail, refer to the many liberal donations and bequests which have been made by generous citizens for developing higher culture—a more comprehensive education. I will, however, be

pardoned for referring to a few, and I may say, without being too enthusiastic, that the future is aglow with promise. The high-hearted examples which have been set will be followed by other favorites of fortune, until this country may surpass the world, not only in common schools, but in her institutions for broader and deeper education.

In looking at this promising future, may we not hope that before another half century closes students from the old world will flock to this, to sit at the feet of the wisdom here installed? Is it too much to hope that, in the not far-off future, the preliminary education of our students will be equal to that required in the best schools of the world?

Defective as has been much of the material, yet have we not produced some marked results? Our best are equal to the best anywhere; mediocrity always and everywhere finds its own. The poor in medicine, the weak brother, however much we may deplore him, however much we may train him, we have, like the poor, always with us. This is the lot of humanity in all lands, among all people, new or old.

A word as to the physical qualities of "The Coming Doctor." Recently a distinguished foreign traveller, in speaking of our educational facilities and national peculiarities, said: "Students are much calmer than their colleagues in Europe. They don't at all trouble themselves about politics or affairs outside their line of duty, and with the practical sense which animates the nation they try to make the best use of their time. They fight no duels, and it is only for health and recreation that they take part in various sports and games." These remarks apply with equal, in fact, with greater force, to medical students.

It is to the country schools, not the city-bred, that medicine must look for many of her strong recruits. Cities too often emasculate—young men are vitiated by indulgence and vice before they become possessed of serious thoughts, before they realize the elements of a healthy, vigorous life. It is this country-bred, this excellent material which is, as we have seen, yearly growing better and better qualified to enter upon the duties of the profession. From these we must look for the men of distinction, the leaders of the future.

Is this picture overdrawn? One word more. In many of the States of the Union, in addition to the liberally supported free schools and schools for higher education, already colleges have been established through the munificence of the General Government, in which the degrees of A.B. and A.M. may be obtained. They are absolutely free colleges, at which the poorest boy in the commonwealth may receive a classical education. And here you will allow me to say, we cannot insist too strongly upon the necessity of classical education; without it the medical man must ever be at a disadvantage. Without a knowledge of Latin and Greek, sure and distinguished success is uncertain. The student may neglect algebra and the higher mathematics, but let him, by all means, have a liberal knowledge of languages.

At the last commencement of one of our Western schools, "forty per cent. of the graduating class had been admitted on diplomas from literary or scientific colleges. The balance of the class had received from one to five years of academic or collegiate instruction." This college is without endowment—depending entirely upon the learning, devotion, and sacrifice of the faculty.

But to return. Prominent among the States in providing institutions for advanced culture, the great frontier State, Texas, claims a high position. The University of Texas will be one of the most liberally endowed; millions of acres of land have been donated for University purposes. There, in that Empire State, may yet be seen one of the greatest schools of literature, science, and philosophy on the Western Continent. The University of Virginia, projected in the early days of the century, by her great commoner, Thomas Jefferson, has yearly sent forth graduates equal in all the elements of advanced scholarship to those from any school. This may seem high praise, but the records of her alumni justify me. The same may be said of Harvard, Yale, Princeton, Columbia, Cornell, and most of our older institutions. The University of California has already an annual revenue of about $200,000. The Michigan University, with a yearly income of almost a quarter of a million of dollars, has well nigh two thousand students, taught by more than one hundred teachers.

Let us not, gentlemen, be impatient; the influences are already projected which will give us students equal to—up to—the highest standard of preliminary preparation. If we have accomplished so much in our primitive stage, what may we not expect when all our great preparatory works come fully into action?

From this view of the resources from which medical students are to be drawn, and of the liberal preparations and facilities for their culture, we may well ask, what is the profession doing to profit from such advantages?

Some of the classical schools at Oxford and Cambridge were organized as early as the thirteenth century, but the systematic, scientific study of medicine and surgery came long subsequently—not for four hundred years later—about the middle of the eighteenth century. It was first projected in Great Britain, and soon after in our Atlantic cities. Unlike the Old World, our fathers had a wilderness to conquer before progress could be made. When the Pilgrim Fathers left England, reading and writing were rare accomplishments; chimneys in that country had just been invented, and flock beds were luxuries. The adventurers—the emigrants to these shores from that ancient and imperfect civilization—had much to learn, but in the midst of their pitiable ignorance, facing great hardships and pressing wants, they were quick to provide educational opportunities for all. The result of their efforts are apparent—they are before us. Could more have been accomplished in one century?

MEDICAL SCHOOLS.

Our medical colleges now number a few more than one hundred. They may be classed as: (1) Metropolitan, those in large cities. (2) Medical colleges in less pretentious cities. (3) Medical colleges in small cities. (4) State medical colleges. For convenience, however, we may speak of them as Metropolitan and Provincial.

Before speaking more definitely of our medical institutions, allow me to refer for a moment to the proposition, that medical schools in our country have been developed by the labors, by the self-sacrifice of the profession. As previously stated, it may be said that in this country everything is endowed except medical colleges,

schools for teaching medicine. Yes, all financial responsibilities have been and are assumed by the faculties, by men who give every hour not devoted to "earning the guinea" to college work, and in most instances, without pecuniary reward. It is only recently that the wise, the generous, the favorites of fortune, and a few of the States, have conceived the idea of endowing medical schools, institutions where medicine and surgery can be cultivated without the embarrassments of financial responsibility. In the presence of such facts, the work of the grumbler seems indeed ungracious.

In our metropolitan colleges, every physician may feel a just pride; their graduates, most of them, will compare favorably with those educated anywhere on this earth.

The accomplished Dr. Senn, after a liberal experience with foreign schools, said: "There is no question in my mind, that the average American student learns more in one month than the average German student in three. He learns more, not because he has better teachers or better facilities, but he makes better use of his time. I am satisfied that in our last graduating class I had at least a dozen students, who, after studying three years, would pass a brilliant examination in any English or German university. They would have felt at home, even in a dress coat in Volkmann's klinik passing their final examination."

Provincial schools do praiseworthy, yes, thorough work in training young men, not only in rudimentary branches, but in practical clinical studies. Many supplement these by hospital attendance in the great cities, and by post-graduate courses. It is gratifying to know that these organizations are being established in all of the great medical centres.

The advance in medical education is again most distinctly pronounced by a remark recently made by one of our distinguished fellows, an American-bred physician, of whose fame we are all justly proud. In a conversation, Dr. Battey said: "When I began practice thirty years ago, there was scarcely a graduate within fifty miles of my residence; now, however, there is hardly a practitioner in the same territory who is not a graduate, and, year after year, a portion of our young men leave home to avail themselves of clinical advantages, to attend post-graduate instruction."

Could anything show more forcibly the conservative and steady growth of medical culture?

HAVE MEDICAL COLLEGES INCREASED TOO RAPIDLY?

Should they be established in small cities, where clinical material is limited, where it must be comparatively scarce? Before answering this, it may be well to reflect upon the proposition, that in our own country, as well as elsewhere, great achievements have often been made in the provinces, and not always under the shadow of the universities. One of the great operations waited for years for a metropolitan disciple—one to take it up—and that, too, long after the provinces, at home and abroad, had demonstrated its vital utility, its claim upon the scientific and skilful surgeon.

As our population increased from three to sixty-five millions, the demands for medical men were great—colleges increased necessarily. Have they multiplied in undue proportion?

In answering this question, I beg again to quote from my beloved master, Samuel D. Gross, to whom this question had been put. After mature deliberation, he said: "Our colleges are not annually graduating one physician for each county in the States and Territories. This is certainly not exceeding the demand." A considerable proportion of those who graduate never enter the ranks—death and desertion claim a large share. It would simply be impossible for the metropolitan schools to graduate all required.

For the introduction of young gentlemen into the profession, there is a mutual responsibility between teachers and preceptors. In very truth it may be said that colleges do their duty, their very best, with the students furnished by the preceptors. Give us liberally educated young gentlemen, and we will furnish graduates worthy of the degree. Medical colleges, however, do not make the physician. They merely furnish the foundation work; the individual must do the rest. In no place is evolution so marked—the fittest will and should survive.

LABORATORY WORK.

Huxley says: "The microscope extends the realm of pathological anatomy to the limits of the invisible world."

"The intimate alliance between morphology and medicine has made the natural history of disease attain a remarkable degree of perfection."

Dr. George M. Sternberg, the distinguished pathologist, recently connected with the Smithsonian Institution, in referring to some of the laboratories established in this country for the study of pathogenic microörganisms, says: "It is no longer necessary to go abroad for instruction in this department of science, since the laboratory of Prof. Welch, in Baltimore, and the Hoagland Laboratory, in Brooklyn, afford facilities which are unsurpassed by any of the laboratories of the old world."

Indeed, it may be said that provisions for the study of pathogenic microörganisms are established in most of the leading schools of this country—in New York, Philadelphia, Boston, Baltimore, and the cities of the West and South.

You will pardon me for mentioning some of the investigators.

Johns Hopkins University has for its director Professor William H. Welch. The Hoagland Laboratory, of Brooklyn, New York, established through the generosity of Dr. C. N. Hoagland, has been built and equipped in the most complete manner for research work in bacteriology and experimental pathology. Professor George M. Sternberg is to be the director of this advanced institution.

At the University of South Carolina, Dr. Meade Bolton, who has had the best of training at Berlin and Göttingen, is at the head of a laboratory. Dr. H. C. Ernst has the direction of a Bacteriological Laboratory in connection with the Harvard School of Medicine.

Prof. James T. Whittaker, who had the honor of being the first American student of Robert Koch, demonstrated, at Cincinnati, in 1882, the tubercle bacillus, after a lecture upon the subject before the College of Physicians of Philadelphia. In 1887 the Medical College of Ohio imported a complete outfit for bacteriological study. The conductors of the laboratory, Drs. Rachford, Cameron, and Freeman, during the first course, had the oppor-

tunity of doing some good work in the discovery of the typhoid bacilli in the reservoir supplied from the Ohio River, then at a very low stage. This discovery led to the general adoption in the city, as advised by leading physicians, of boiling all drinking water, a plan which undoubtedly limited the spread of the disease.

Among others may be mentioned Dr. Prudden, of the College of Physicians and Surgeons, New York; Dr. George A. Kemp, of Brooklyn; Dr. Mall, of Baltimore; Dr. Booker, of the same city; and Dr. Frank S. Billings, of Lincoln, Nebraska.

One of the earliest, most accomplished and accurate cultivators of microörganisms is Dr. James E. Reeves, of Chattanooga. His technique is singularly beautiful. Many of his preparations are to be found in the National Museum.

Dr. Victor C. Vaughan and Dr. Heneage Gibbes conduct laboratory work at Ann Arbor.

The University of Pennsylvania has at the head of its laboratory Dr. John Guitéras, a pathologist who has distinguished himself in the study of the origin and spread of yellow fever.

Thus it will be seen that in all parts of our country—East, West, North, and South—laboratories are being established for original work.

HISTORY OF MEDICAL TEACHING IN THIS COUNTRY.

A brief review of medical teaching in this country will be pardoned—it may be profitable—it will certainly illume the present, and may be somewhat of interest to the future.

The first medical lectures were delivered by Dr. John Morgan and William Shippen, in 1767, in Philadelphia. Dr. Rush and Dr. Physick soon after participated, and in 1768 the medical department of the University of Pennsylvania was organized; that great school which is steadily advancing to the highest station. Philadelphia was a small, a provincial city at that time; now she is only second to the great metropolis in numerical strength, but second to none in the thorough equipment of her medical schools.

Contemporaneous with Philadelphia, an organization was projected for medical instruction in New York. In 1767, the first steps were taken which resulted in the school, ever since known as the "College of Physicians and Surgeons," one which challenges the confidence of all. The medical colleges of New York, endowed, not by government, but by her public-spirited citizens, have won the honors which they wear so well.

In 1785, the first school was organized in Boston. The chairs were four, and the session four months. Harvard is the outgrowth of this humble beginning of that provincial faculty.

In 1800, the first medical instruction was given in Baltimore; since then, the schools of Maryland have occupied a deservedly high position. Recently one of her citizens made an endowment by which the "Johns Hopkins University" will be equipped for the most thorough work, experimental work, laboratory studies, a range and grade of investigations *en rapport* with the spirit of the times.

This great benefactor has also given to Baltimore one of the most completely equipped hospitals to be found on this earth.

The great Mississippi valley was yet unknown, but soon after the close of the Revolution emigration began, and, as early as 1799, Dr. Samuel Brown organized the medical department of Transylvania University. Dr. Benjamin Dudley effected a reorganization in 1819. This school, after many prosperous years, having graduated men who acquired distinction at home and abroad, was transferred, or, rather, most of the faculty removed to Louisville, when and where the University of Louisville was founded.

During the early part of the century, medical schools were organized in several of the Eastern States, usually under State or church patronage. Most of them exist to-day. Some of the most distinguished men in our profession have been associated with these institutions.

As the West and South were peopled, medical schools were established in cities and promising towns. As early as 1819, Dr. Daniel Drake secured the charter of the Medical College of Ohio, and had it legally connected with the City Hospital. The faculty constituted the hospital staff, the members of which were required to give clinical lectures—the first forward step on the continent in blending didactic with clinical instruction.

The physicians in South Carolina began medical teaching in 1823, and those of Louisiana in 1835. In both of these States schools of high character have been maintained.

In closing this very brief review of our colleges, metropolitan and provincial, I think it may be said that year after year the standard of the doctorate is being elevated, preliminary examinations and graded courses are being adopted; the smaller schools, to which most blame is attached, whether justly or not, with a disregard of self-interest seldom seen, are yearly reducing the size of their classes by insisting upon higher preliminary education, by extending the curriculum and by graded instruction.

MEDICAL JOURNALS.

Medical journals, metropolitan and provincial, are the heralds, the vanguards of medical progress, the exponents of professional culture. They are closely associated with the colleges in education and in post-graduate instruction. In them appear the best thoughts of the best men; they constitute the great forum of intellectual combat; upon their pages pretension is analyzed and estimated, and worth recognized; that which is new or original is endorsed, or rather encouraged; it is only the plan, the original investigation which is endorsed; the results, the conclusion must be subject to the crucible of test and trial.

The London *Lancet* and *The American Journal of the Medical Sciences* were almost contemporaries—who can overestimate their value—their influence in medical progress. While our journals, both metropolitan and provincial, are freighted with the best thoughts of the best men, yet, it must be confessed that trash and light material—very light material—may be found in all, but the reader, nevertheless, will find much that is not worthless.

The Journal of this Association has won its way to its present high position by its dignified course and its essentially scientific character; but has it reached its full usefulness? A learned and distinguished author, and a highly prized fellow of our Association, at my suggestion, gives his views upon this question.

Dr. Comegys says: The undertaking, seven years ago,

to establish a weekly journal, was a happy conception and has been carried on as successfully as the resources of the Association would admit. To Dr. N. S. Davis unstinted praise is due; proportionate praise is also due the Board of Trustees with whom he has been associated.

"A large number of members believe that it is entirely feasible to enlarge the Journal and give to it increased capacity for usefulness; indeed, that it should be made more fully capable, as the organ of the Association, to assert and maintain the dignity and power of the medical profession as one of the greatest factors in civil life; that to it society must ultimately turn to find not only the resources to assuage the distress arising from the diseases and accidents of life, but for its protection from all those evils that fill the land with apprehension of desolation and ruin.

"We know to what an immense extent we can estop the approach of the pestilences that desolate lands, and which menace, through the paths of commerce, the whole area of civilization. We know what we can do to improve the homes and places of labor of the lower and toiling classes of cities and other crowded centres of population. There is nothing, indeed, connected with our own social state, which the medical profession should not supervise and which it should not have the power to control. A great organ is necessary to enlighten, strengthen, and lead the profession in all directions, to bring to bear its beneficent agency for the correction of the terrible evils of society.

"Such a journal must be made encyclopædic in character, in which can be found the proceedings of distinguished societies of this country and of Europe, the work of the chief actors of medical progress in all parts of the world. Twelve thousand subscribers would give $60,000, this would insure $40,000 from advertisements, making an income of $100,000, which would sustain one of the grandest journals in the world.

"The *British Medical Journal* in fifteen years has fourteen thousand subscribers and an income of $125,000. May we not hope to reach this? and when we do, who can compass the good which the American Medical Association will accomplish?"

THE MEDICAL AND SURGICAL LIBRARY AND MUSEUM AT WASHINGTON.

Another important factor in professional culture is the great Library and Museum at Washington, evoked by the efforts of an American-bred physician, John S. Billings. The Library of the Surgeon General's Office of the Army now contains 92,000 volumes and 137,000 pamphlets, being the largest collection of medical literature in the world, and it is not only the largest, but the most useful. This is because it has an Index Catalogue, which not only shows what the Library has of the works of any author, but, for any given subject, indicates all the original articles in journals and transactions, as well as the books and pamphlets which relate to it, and thus forms a medical bibliography which saves an enormous amount of time and labor to those engaged in medical literary research. This catalogue is being published at the rate of one volume a year; nine volumes have been issued and six more will complete the work. The Army Medical Museum is a great pathological school, and now contains over 15,000 specimens, being one of the largest museums in the world, and richer than any other in illustrations of military medicine and surgery. This Library and Museum are national in scope and character They have at last been securely placed in a fire-proof building well adapted to their needs, thanks to the efforts of the medical profession, and we should see to it that they are maintained and increased to the highest degree of completeness and efficiency.

The medical profession asks very little of the general Government, but it does ask that these two institutions shall be made as useful as possible. The number of copies of the Index Catalogue which Congress authorizes to be published is hardly sufficient to meet the demand, and the repeated requests for authority to publish an illustrated catalogue of the Museum for distribution to the profession, have not yet received any attention from Congress, and it is time we took the matter in hand. When we, who are the family physicians of our senators and members, say to them, that this is the thing that ought to be done and must be done, it is pretty certain that it will be done. There is nothing that will do more to promote higher medical education, to stimulate research, and to crown American medicine with honor, than to give ample means to this great Library and Museum to obtain materials and to publish widely the results.

MEDICAL AND SURGICAL HISTORY OF THE WAR.

This matchless record of military medicine and surgery is a marked testimony to the profession of our land. Let us for a moment compare it with similar work elsewhere. After the great Crimean war was over, its experiences were collected, weighed, and analyzed; how strange, in the light of present surgery, and in what contrast with the lessons taught in our great conflict, is the record of McLeod upon one vital operation—trephining for fractures of the skull. In his *Notes on the Surgery of the Crimean War*, that distinguished gentleman says:

"If any patients were lost from not having been operated upon, I never saw any of them, but I do know of some patients who died because they were subjected to operation."

And what a fearful commentary upon the military surgery of that campaign McLeod makes when he writes:

"Thus it would seem as if severe fatigue, irregular, and it might be intemperate diet, are less injurious to men with fracture of the skull than the probings, pickings, and trephinings which form the more orthodox and approved practice."

It may be truly said that the judicious use of the trephine during the conflict between the States, supplemented after the war by American surgeons, especially by one of our fellows, Prof. W. T. Briggs, led up, led surely, safely, and steadily to the achievements of Victor Horsley, the master of us all in brain surgery.

MEDICAL SOCIETIES.

Our medical societies, local and national, are great factors in professional progress. Not alone are they valuable for their social opportunities, but in and through them a vast amount of valuable matter is presented.

MEDICAL LITERATURE.

Had Sydney Smith been a physician and given to reading, he would not, even in 1820, have asked the

questions, "Who reads an American book?" "What does the world owe to American physicians or surgeons?"

This reverend gentleman, this famous critic, could not have heard of Ephraim McDowell, whose brief paper, detailing his first three cases of ovariotomy, published in the Philadelphia *Eclectic Repertory* in 1817, was of more value, did more for the conservation of human life, than a score of ordinary publications. Our first half century may be poor in books, but it abounded in strong, brave, conscientious and devoted men, who, with the most limited resources, accomplished the grandest results. They compelled success because they deserved it.

The ink was hardly dry upon that cynical pen when anæsthesia was presented by the profession, so poor, as he supposed, in valuable works.

But what country or age can match, in great contributions to the relief of the suffering, McDowell, Sims, Bigelow, Sayre, Battey, and Emmet, and that trinity of men —Wells, Morton, and Jackson—who gave anæsthesia to the world. Think of anæsthesia and of its influence upon the progress of medicine and surgery. But yesterday a writer in the London *Lancet* gave a graphic history of its reception in London; how the great Liston, having a patient who could not nerve himself up to the point of consenting to have a limb amputated for strumous disease of the knee-joint, decided that "if the insensibility could be insured and maintained for one minute, he would amputate." Reflect for a moment on the hesitancy of the great surgeon of University College Hospital, as he stood by the side of that patient; he could hardly believe the novel report as it came from over the sea. Willing and anxious as he was to operate, he hesitated to urge the poor patient to make the experiment—experiment it then was. In a week, however, it was legitimate practice all over the world.

The heart of every American physician is filled with thankfulness when he remembers that in the providence of God this great boon to humanity was vouchsafed to his country. The very ground upon which stands the Massachusetts Hospital is sacred to us all. Associated with the discoverers must ever be the name of Dr. Hayward, who performed the first operation under the strange Letheon. Previous to this, operative surgery was slow, tedious, and almost cruel. Contrast it to-day with what it was previous to 1847. What grand strides it has made under the direct support of anæsthesia and its almost equal co-laborer, antisepsis; the great cavities are invaded, and invaded safely; the abdomen has become a familiar field, and who can forecast the surgery of the brain?

Since Emmet's operation we hear no more, neither in this country nor abroad—neither in London nor Berlin, neither in Paris nor Vienna—of that culmination, that *ultima thule* of ignorance, "ulceration of the os." What a disgrace that term was to the surgery of the world?

The ignorance of diagnosis was only surpassed by the cruel treatment which it evoked, the application of caustics to the tender everted membrane of the cervical canal.

Has the operation, Bigelow's litholapaxy, the crushing and evacuation of a stone at one sitting, been truly estimated? Its adoption in one celebrated case might have changed the destinies of Europe. Previous to Bigelow lithotrity was an uncertain and, in most hands, a cruel operation: "Crush all possible at a short sitting, and allow the fragments to pass *via naturales*." Bigelow realized that if anæsthesia is safe for two minutes, it is safe for two hours or more; hence, he said, "Crush it at once, and evacuate the bladder by an aspirator." The operation, in proper cases, is as practical as the description is brief and efficient.

The accomplished Edmund Owen, M.B., F.R.C.S., upon calculus says: "With rare exceptions only two operations are now practised—suprapubic lithotomy and crushing with evacuation at a single sitting." A high compliment from an eminent authority.

The story of Ephraim McDowell, though so often repeated, humanity never tires of hearing. To us he belongs, and to us only; we cannot share his fame with another; we would not if we could. Who can measure the relief which his operation has bestowed upon suffering woman?—not only woman, for his was the genius which opened the way for laparotomy in both sexes.

CLOUDS.

What has been accomplished by the profession in this country, self-reliant and, as we have heretofore said, without governmental or social support, is certainly worthy of congratulation, and gives ground for hopes of a rosy-hued future; but alas! there are some dark clouds to be seen—some spots on our sun of promise! Have we inherent defects in our organic law—our *esprit de corps?*

Upon the face of our promising future some omens of evil appear, indications which look not up but down, not forward but backward, not to the elevation but rather toward the degradation of our profession. Heretofore we were an organization into which no species of fraud could enter, pretension, ignorant pretension, stopped at the door. No *ism* or *pathy* was admitted; something more than a diploma, "a legal diploma," was required—a clean bill of conduct, free from false assumption, assumption of universal knowledge, of specific remedies, of imaginary potencies; in fact, of all shams and false claims, a guild in which there was the greatest freedom for the truth, the largest liberty for the right. No vendor of secret remedies was admitted, because of the ignorant presumption in which they were conceived and propagated; but, alas, that we should have fallen upon the evil times when "patented processes" are attempted, when "processes" of valuable remedies are kept secret. These remedies with "patent processes" are in daily use. This is one of the dark spots in the picture. It came in with the "legally qualified practitioner." What is antipyrin, antifebrin, salol, sulphonal? The reliant patient may well propound such questions. Who can answer them? Are we relegated at one fell move back into outer darkness, the associates of vendors of "secret remedies," of "patented processes?" What higher is a "patented process" than a "patented nostrum?" The profession was never so low as to countenance the latter; but have we not in these later days become propagandists of patented, and, therefore, secret processes?

LAWS FOR THE REGULATION OF THE PRACTICE OF MEDICINE.

It may be asked, Has the standard of professional excellence been raised by laws enacted in many of the States for the regulation of the practice of Medicine?

These laws banish the poor creatures without diplomas, but make respectable, *quasi*-respectable, all who have so-

called diplomas from whatever source. Shams and pretenders are in this way made "legal," and claim whatever protection and recognition that term may give or imply. A chartered institution, in most of the States, represents a formal application for incorporation to a Secretary of State, the signature of that officer, and nothing more. The process of graduating from such—the faculty often consisting of but a single person, or a man and his wife—would hardly be called a farce; the subject is too serious. "Legally qualified!" think of it; and yet this legally qualified creature will claim and expect to meet the highest and the purest. Is this an advance upon the requirements of the Code, the morals and *esprit de corps* of which have never been questioned?

What has been the effect of these diplomas? Have they not tended to make vice and presumptuous ignorance respectable?

Let us be true to ourselves; pitch cannot be touched without defilement. Our Profession must be kept pure, or else it will degenerate and sink to the level of a trade.

In State Boards of Health, by the side of physicians, we find these "legally qualified" practitioners. Where lies the responsibility? Is it with us? Our self-examination on this subject should be searching. If we have failed in our duties to humanity, let us be swift to acknowledge it, and be still more eager to correct our error.

The presence of this body of professional gentlemen, representing our entire country, furnishes sufficient argument for the existence of a National organization; one embracing the virtue and strength of the profession, one to which all questions should be referred for just and final decision. Questions will arise, differences of opinion will occur between honest men. We must have some tribunal, some body, to which these questions, these differences of opinion, can be relegated for solution. The golden rule is a principle, not a law; it cannot interpret itself. Its application to life in detail must be defined. In this respect we are like other men and other organizations. Our morale, however, is higher; it has a zeal, a spirit, a hope and confidence peculiarly our own. If we would have our organization pure, we should make it strong—strong enough to eliminate all that is not true or truthful. We are mortals; not transcendentalists. We cannot live as the commune. We must have laws; remembering always that they are not made for the righteous, but for the sinner. "They that be whole need not a physician, but they that are sick." I will not attempt to defend the ethics of our profession. It would be a poor compliment to your intelligence, to your manhood; for there is not a clause in our Code which a gentleman could not cheerfully obey. Organize whatever we may please: Associations of Specialists, of Physicians, of Surgeons; Academies of Physicians; Congresses of Physicians and Surgeons; but let us not lose our loyalty to this parent Association. Projected almost a half century ago, when medical societies were few, it has annually convened—in the North, in the South, in the East, in the West, and in the far West, on the Pacific shore; if you will examine its yearly roster, you will find that it embraced the best and the wisest. Almost all who were present at the beginning are at rest; their places have been filled by worthy men. Thus, yearly new life—new men being added—this Association cannot grow old.

"When a people hold their lives and property as nothing, the enemy has already suffered defeat." So, too, when virtue will not compromise with vice, the victory, although it may be long delayed, will surely come.

Of the American Medical Association, let us unite in saying, *esto perpetua*.

THE ADDRESS IN SURGERY.

BY P. S. CONNER, M.D., LL.D.,
PROFESSOR OF SURGERY IN THE MEDICAL COLLEGE OF OHIO.

Delivered June 27, 1889.

THE surgery of the century has been of three periods, the preanæsthetic, the anæsthetic, and the modern one. Operative brilliancy characterized the first. The suffering inseparably connected with the use of the knife and the nervous depression resulting therefrom was to be limited chiefly by celerity of execution; hence the swift-moving hand was an essential part of the equipment of the fittest surgeon.

When in the amphitheatre of the Massachusetts General Hospital, "the problem of surgical anæsthesia was definitively solved," a new period began. Pain was no more, and it was permitted to examine earlier and more thoroughly, to remove more extensively, and to operate successfully in regions previously altogether, or in great measure, beyond the reach of art. For twenty years or more, progress was in the line of diagnosis, of development of new and better methods of operating, of extension of the range of surgical interference. Time was no longer an element of prime importance, and the work was regarded as quickly enough done when well and thoroughly done—too much so, in fact, for not seldom the best interests of the patient have been jeopardized by unnecessary delay in execution, that would not have occurred but for the existing profound insensibility. But though operations in this anæsthetic period were without much of the terrors of the olden time, they yet fell far short of producing the wished-for result in preservation of life and early restoration of health. Wound complications were still as ever the bane of surgery, and too often the wisest planned and best executed operation resulted in failure because of the supervention of one form or other of septic infection.

It is scarcely twenty years since patient investigation, careful experimentation, and practical testing began to throw strong, clear light upon that most obscure of the subjects of medical study, the causes of disease. As never before in the history of medicine, truly scientific methods of research have been adopted and pursued by a multitude of trained observers in all civilized countries, and surgery has entered upon its scientific period, in which operator and patient are profiting by the labors of the chemist, the botanist, the physiologist, the physician, equally with those of the practical and experimental surgeon. It seems but yesterday when Lister's early papers startled the world. It is but twenty-two years since the first one was published, yet what enormous advances since then in knowledge, in treatment, and in the field of operative interference! A new department of science, surgical bacteriology, has been created (for what was done prior to 1867 may, for practical purposes, be left out of consideration), and in its development has been worked out the mycotic origin of all those pathological processes

looked upon as inseparable from traumatisms, or almost necessarily associated with them if severe. Suppurations, gangrene, septic infection, erysipelas, tetanus, we know to depend upon the presence or the action of one or other of definite organisms that may be isolated, cultivated, and inoculated. Recognizing the cause it has been comparatively easy to devise methods, more or less perfect in action, to prevent the development or neutralize the influence of it, and there has been worked out an antiseptic and aseptic wound treatment, the results of which are simply marvellous. But just here I must protest against the wisdom or the justice of the sweeping declarations of a few enthusiasts, who see in other than speedy recovery after injury or operation evidences of what they are pleased to consider criminal ignorance or neglect.

The existing strong probability that in any given case septic infection might be prevented, has given warrant for the performance of operations that in preaseptic days were not to be thought of.

Abdominal surgery, that so short a time ago meant scarcely more than the removal of an ovarian tumor too often carried until death was evidently fast approaching, now includes operations upon almost every part of each hollow and solid viscus, and laparotomy has taken its place as a safe, proper, and often indispensable prerequisite to the determination of obscure disease. Penetrating and perforating gunshot wounds, so generally fatal when treated by rest and opium, have in at least forty cases been recovered from after section and suture, and there are now but few surgeons still unconvinced of the wisdom of early active interference. At our last meeting Senn's carefully elaborated and beautiful demonstrations set forth a means of determining the existence and location of intestinal wounds that, if safe, as it has thus far seemed to be, will remove the greatest objection to laparotomy in these cases—the uncertainty in the earlier hours of bowel perforation—and prevent what otherwise will occur, the overlooking of one or more lesions. It is not to be expected that all or any close approximation to all of these very dangerous wounds will be saved by early operation, for great injury will ordinarily be produced by the bullet, be it large or small; but every case that recovers after section and suture may fairly be considered as rescued from an otherwise almost inevitable death. Unquestionably the laying open of the peritoneum and operating upon an abdominal organ has at times been carried too far. Useless work has been performed, and life has been sacrificed, for it is not true (so far certainly as operators in general are concerned) that abdominal section is in itself without danger, doing no harm if it accomplishes no good. But not a day goes by that somewhere or other life is not prolonged and comfort secured by an intraperitoneal ligation, suture, anastomosis, or excision, rendered proper, may we not say possible, only by the aseptic results of scientific discovery and experimentation.

So, too, the diseases and injuries of the other great cavities are being attacked by the surgeon's knife guided by the diagnostic knowledge, the localizing exactness and the technical skill of the physician, the physiologist, and the vivisector.

There has been but a beginning of intrathoracic surgery, though for years empyemas have been treated by free incisions, supplemented not seldom by extensive excisions of portions of the chest wall, and even in preaseptic days deeply lodged foreign bodies were removed. Only very recently has the lung been cut into for the evacuation of abscesses and the treatment of gangrenous areas, such pneumotomies resulting favorably in one-half of the reported cases; and as yet but few subpleural tumors have been attacked. There is every reason for believing that in the near future surgery will be able to render great service to the subjects of not a few forms of thoracic disease now regarded as beyond the reach of art.

The most recent and the most brilliant triumphs have been in the treatment of diseases and injuries of the brain and cord. Nowhere else have our art and science so joined hands in affording relief as here. Tumors removed, foreign bodies taken away and their tracks drained, convulsion-centres excised, serous effusions tapped, life preserved and comfort secured; so reads the record. Much remains to be done in the determination of the trouble, the exact localization of the mischief, the perfection of technique. Not seldom mistakes will be made, errors committed, but it will be more and more demonstrated that the trained mind and the skilful hand working together can recognize and successfully treat otherwise irremediable affections within the skull and spinal column. As the operative procedures necessary for the exposure and removal of the spinous processes and laminæ of the vertebræ are but little dangerous, and as septic meningitis can almost certainly be prevented, a change may reasonably be looked for in the treatment of vertebral fractures, especially those in the lower half of the column. Up to this time the cases in which active interference has been made have almost always been those of long duration, in which existing inflammatory changes in the cord, if nothing worse, could not but prevent any favorable result; but even in these, of late, the patient has been none the worse for an operation. Without doubt, early removal of pressure, whether made by bone or blood it matters not, would save many a one from all those deplorable conditions consequent upon myelitis with which we are unfortunately too familiar.

Is there any good reason why spine fractures should not be treated as skull fractures are? and who would now for a moment think of rest and position as the routine treatment of the latter injuries?

But in this scientific period there has been much more accomplished than extension of the range of operative interference, great and important as this has been. As never before it has been possible to preserve damaged parts and to retain important functions, to replace completely detached pieces of bone and secure adhesion as perfect as of the fragments in a simple fracture, to transfer large areas of integument and engraft pieces of bone, to supply deficiencies in soft or hard parts by skin or bone from dog, rabbit, chicken, or frog. Every department of conservative surgery has been and will yet more be benefited by the preventing of the evils consequent upon the action of minute organisms.

The two diseases that produce the widest destruction to part and to life are tuberculosis and cancer. The former that until the discovery of its causative bacillus was regarded as of rare occurrence in parts belonging to the domain of surgery, is now known to be the producer of the vast proportion of the diseases of bones and joints, and of many of those attacking the skin and more ex-

ternal organs. Primarily, and often for a long time local, if allowed to go on unchecked it affects other and remote regions, perhaps rapidly becoming generalized. What has been learned respecting it—that it may attack any part the blood circulation of which is disturbed by general enfeeblement or local injury of ordinarily not severe character; that the bacilli may be destroyed or become encapsulated; that the softened tissues may, in like manner, be taken up and carried off or shut in temporarily or permanently; that if the diseased focus be completely removed, as it often may, the part and the whole are as if it had never existed, except so far as function is disturbed by the loss of what has been taken away and by the scar tissue resulting.

How has treatment been affected by this knowledge? It is of prime importance that early diagnosis be made. Located in bone or joint, and detected while yet limited, prolonged rest, as absolute as possible, will in the majority of cases, certainly in young subjects, secure destruction, absorption, or encapsulation of organisms or affected cells with resulting restoration to health. Advanced to the stage of caseation and liquefaction, rest may yet be followed by recovery, though ordinarily free drainage, with or without associated removal of the infected tissue, will be of great advantage. Injection of agents, such as iodoform, or the acid phosphate of lime, that will destroy the bacilli and the tuberculous masses, may produce the wished-for cure. But ordinarily it will be better, indeed generally necessary, to remove the affected area either by formal or informal excision or by amputation. Whether diseased joints are best treated by arthrectomies or by typical excisions is one of the questions still *sub judice*, though in the last three years, as never before, it has been shown that formal removals of the larger articulations can in a large proportion of cases be followed by early repair and solidification without suppuration or constitutional disturbance—even at times with recovery of original function. Although it is not likely that it can ever be said with truth that the days of the lame and the hunchbacked have gone by, because of neglect, delay, or generalization of the pathological process, yet we have good reason to believe that further advances in the knowledge of the development and extension of the tuberculous disease will enable the surgeons of the future so to limit, ameliorate, and cure the surgical tuberculous affections as that they will no longer constitute one of the most, if not the most, important and destructive of the external diseases.

Of cancer it may with truth be said we know very little; yet of nothing do we more need knowledge. Much less often met with than tuberculous disease, it is yet of not infrequent occurrence. In our eight largest cities (Boston, New York, Brooklyn, Philadelphia, Baltimore, Chicago, St. Louis, and Cincinnati) during the five years ending December 31, 1888, of 599,684 deaths from all causes, 13,094 were from cancer, 2.19 per cent.; and, as we all know, the disease is not peculiarly an urban one. In five of the eight cities, New York, Chicago, Cincinnati, Brooklyn, and St. Louis, the death-rate was much the same, being, in the order given, 2.1, 2, 2, 1.94, 1.93 per cent. In Boston it was the highest, being 2.98 per cent.; in Baltimore it was 2.4 per cent.; and in Philadelphia 2.28 per cent. In Cincinnati, in the last year, the percentage reached 2.6, while in 1868 it was but 0.55; an altogether exceptional rate, as only once since has it fallen below 1 per cent., in 1870, when it was 0.8. For these figures I am indebted to the Health Officer, Dr. Stanton. One in fifty, then, of the deaths in an aggregate city population of over five millions is due to this disease; and if we have regard only to the mortality of those within the cancer age—*i. e.*, more than thirty-five years old, about one in twenty of the deaths is thus produced. Even among the carefully selected adult individuals carrying life insurance, who are free, or are supposed to be, from family predisposition to cancer from 2.5 to 3.5 per cent. of the mortality is from this disease.

The statistics just mentioned, and, particularly, the marked contrast between the high death-rate in Boston and the low one in St. Louis, give but little support to the theory of Haviland, that low lands subject to frequent overflows are those in which the disease is most prevalent. In preparing the mortality statistics of the census of 1880, Dr. Billings found that the disease was most prevalent in New England and Southern California, and least so in the South and upon the Mississippi. It is to be hoped that in the preparation of the vital statistics of the next Census such attention may be given to this subject of occurrence and distribution, and such full and complete reports secured as will add materially to our knowledge, and go far toward determining the correctness or incorrectness of the views of the English writer named. Care should be taken to separate, if possible, cases of sarcoma from those of cancer. Hirsch to the contrary notwithstanding, this affection is probably becoming more common throughout the civilized world; certainly is so in our own country and in Great Britain. Increased accuracy in diagnosis will not account for a doubling in twenty years of its mortality-rate in Massachusetts, or in Cincinnati, or in less than twice twenty years in England.

Frequently, if not usually, attacking individuals in good general health (though oftentimes appearing soon after a period of marked mental anxiety and depression), it has regard neither to social conditions nor hygienic surroundings. Unlike consumption, which is often of limited duration, ending in recovery, and at the worst, ordinarily bringing death gently, cancer left to itself very rarely is spontaneously eliminated, is almost inevitably destructive to part and to life, and is often attended with severe physical and mental suffering.

What is its starting-point? An unused long-dormant embryonic cell, at length aroused to activity by local irritation, general enfeeblement, or nervous exhaustion? In all probability, no. An abnormal epithelial development, abnormal because unconfined within its normal limits? But why unconfined? An epithelial cell undergoing proper degenerative changes, but arrested at some point short of its complete alteration? What stops its retrograde movement? Is it of mycotic origin? That it should be so would hardly be more strange than that lupus or lepra should be. That it is so has not yet been proved. The many investigations that have been made, some of them for a time apparently fruitful, have thus far failed to discover a causative bacillus, unless farther and extended cultivations and inoculations shall prove that Kübasoff has actually found it. Experimental inoculations have again and again produced no specific result, but Lampiasi has claimed that by using a bacillus culture from the blood he succeeded in causing in a healthy part of the patient's skin the growth of a nodule having "an

alveolar stroma with wide meshes, which contained many epithelial cells of different form and size," and Hanau has twice successfully transplanted from rat to rat.

No more inviting field is open to the competent bacteriologists and experimenters of our country (and we have a number of them, as also well-equipped laboratories) than this very one of cancer. Cases are numerous, specimens are being daily secured, and there is no reason why America should not now do full part in settling the vexed questions of nature and origin. The imperative necessities of a struggle for existence, and the intense practicality of a new and developing country, have heretofore prevented any but the very few filled with enthusiasm, or independent of fortune, from engaging in purely scientific studies involving minute investigation and patient labor with often no apparent practical outcome. But the times are changing, and the profession of our country, may and doubtless will ere long, be as well and favorably known in biological research as it has been and is in relation to ovariotomy, to ether, to the hip, to the treatment of stone, to the surgical diseases of women, to abdominal section, to a multitude of affections and the means of treating them.

As we see it in lip or breast or uterus or stomach, or it matters not what part or organ, is cancer a local disease, or but a local manifestation of a constitutional state? The question is still an open one, though the great majority of pathologists and clinicians are now agreed that wherever seated, it is primarily and for a time purely local, whatever may be the general conditions inherited or acquired that permit or favor its development. If not of limited area and capable of complete removal, operative interference can be justified only on the ground of affording temporary relief—unfortunately, all that is accomplished in the majority of cases submitted to the knife. But there is great encouragement in the knowledge that a certain percentage of patients operated upon do recover, that is, remain free from recurrence for three or more years; and that this percentage is larger or smaller, according as the disease is so situated as to be early detected and thoroughly removed, or the contrary. Located in the lower lip or cervix uteri, for example, two out of five patients operated upon get well, in the breast one in eight. Why this great difference? Because, we may believe, of the site itself, and of the degree and rapidity of extension in parts immediately adjacent, and of glandular involvement; in other words, of the likelihood of early and the possibility of complete extirpation, or the opposite. How are to be regarded those cases in which, after five, ten, or twenty years of apparently perfect health, the disease again shows itself and destroys life? As of long quiescence of infected and infecting cells, or of a new and independent affection? The latter explanation certainly makes a far less demand upon our credulity, and it is no more strange that there should be a second than a first attack in a person and tissues possessing an undetermined and unknown receptivity, and such there certainly must be that cancer may be developed at all.

Of nothing are we more certain than of the immense advantage there is in early recognition and speedy removal; and, on the other hand, of the utter uselessness, so far at least as the ultimate result is concerned, of any surgical interference after wide extension has taken place.

In perfecting, therefore, the means of establishing diagnosis at an early day, lies an important work in the future. Though consideration of age, of location, of pre-existing long-continued irritation, go far toward settling the nature of a given tumor, and upon such estimation of probabilities action may generally safely be taken, yet, as a rule, certainty of the character of the growth can only be had after scientific determination of its anatomical constitution. Whatever, then, makes it possible safely, easily, and without pain, to remove for microscopic examination a sufficiently extensive piece of the mass to show its deep as well as superficial structures, is of much practical value. A convenient and promising little instrument has lately been given to the profession by Dr. Collins Warren, of Boston.

Physiological and chemical investigations have furnished us with early and reliable evidence of the existence of cancer of the stomach, in absence of the hydrochloric acid in the secretions of that viscus; may not kindred investigations give us like aid when other organs are affected?

The modern and scientific wound treatment now enables the surgeon to remove more extensively, and, at the same time, safely, so that active interference may reasonably be expected to be, and is, attended with much better results than could be looked for a few years ago. Much of the work, though that in the last decade has been done upon internal cancers, has been of questionable utility, chiefly because of its late performance.

What will the future reveal respecting the non-operative treatment? Will a drug or drugs be found to secure the destruction and removal of the morbid mass? May the moderate continued electric current long employed, or powerful interrupted currents "flashed through," produce, as has been claimed for them, entire disappearance of the diseased cells? Can some pathogenic organism be inoculated that, without killing the patient, will break down the malignant growth? We all know what has been done with the micrococcus of erysipelas.

In nothing could this Association do more than in determining by collective investigation and thorough committee work the frequency of occurrence of carcinoma in the country as a whole, and in its several States, the relation borne (if any) to geological formation, the age of appearance, the relative affection of parts and organs, the influence of therapeutic treatment, and the duration of life with and without operation. Five years of such work would suffice to accumulate a mass of statistics of very great value, the study of which could not but advance the interest of patients and practitioners; and in this, as in everything else, "many hands make light work." To physicians, surgeons, and therapeutists the subject is one of prime importance, and only by combined scientific and practical work can it be determined what excites and produces the disease, and what can secure its relief.

As we survey the advances, etiological, diagnostic, and therapeutic, made in the few years just past, that are of the scientific period, and consider, even in the most hurried way, the problems that are yet awaiting solution—problems relating to nature, origin and treatment of the diseases and injuries of parts within the domain of surgery—what may we not reasonably anticipate as the future of our science and art! Accidents must occur, diseases will prevail, no matter how great the triumphs

of preventive medicine. Surgical pathology is but in its infancy. Years ago it was declared that operative surgery had reached its climax. Yet since then operations have over and over again been done within abdomen, chest, and skull, upon the larynx, throat, and spinal cord, that in boldness of conception and brilliancy of execution have no parallel in the history of medicine. The end is not yet, nor will be, while, the world over, there are active minds and cunning hands busied with the determination of the existence and extent of surgical affections, and ready and able to remove them, aided more and more by labors of investigators in many departments of science, general as well as medical. Year by year he who may deliver the Address on Surgery will be able to report doubts removed, discoveries made, remedies employed, and operations done.

MEDICAL PROGRESS.

Resection of the Sternum.—In an article on the resection of the sternum in the *Centralbl. f. Chirurg.*, May 25, 1889, DR. G. STEINHEIL says that the operation was first performed by Galen, and used to be most rare. Since the sub-periosteal method was introduced by Ollier it has become more frequent.

Eighty-four cases were reported by Otis as having occurred during the American war, but these Steinheil does not take into consideration, as their history was incomplete. He, therefore, states that thirty-six authentic cases have been recorded. In conclusion he makes the following assertions:

1. The sternum can be successfully resected in part or in its entirety.

2. The difficulty of the operation depends upon the extent of the resection, the portion resected, the cause of the operation, and the method employed, whether subperiosteal or not.

3. In complicated fractures, especially when resulting from gunshot wounds, the result of the resection depends upon the course of the wound.

4. Chronic inflammatory processes are the most frequent indications for resection of the sternum. The subperiosteal method is attended by the greatest success, frequently osseous regeneration will follow. The operation is frequently performed for the removal of tumors of the sternum and mediastinum, and also to form an opening in the chest through which the larger vessels may be tied.

Treatment of Tinea Tonsurans.—DR. A. F. HARRISON, of Bristol, in an article in the *British Medical Journal* for March 2, 1889, alludes to the unsatisfactory modes adopted in the treatment of that troublesome complaint, tinea tonsurans. Dr. Harrison states that the great difficulty of getting at ringworm of the scalp is physical; the parasitic fungus revels and runs rampant in the secure nidus of the hair and hair-follicle, a soil so congenial that it seems to be in some cases ever fertile and ever fertilizing. To overcome this difficulty, and so get at this secure fungus retreat, he indicated that no remedies could be considered highly efficacious which did not act chemically upon the hair matter itself and at the same time carry with them a parasiticide. Upon experimenting, Harrison found that caustic alkalies were most useful hair-solvents, but did not destroy the conidia, and it was necessary to combine other agents with them. After a long series of careful investigations he found that the following ointment gave the best results:

℞.—Caustic potash . . . . grains jx.
Carbolic acid . . . . " xxjv.
Lanolin } . . . . āā ℥ss.—M.
Cocoanut oil }

The ingredients should be well rubbed together, and, if desired, a little oil of cloves, lavender, or rosemary may be added.

When the disease occurs in a family he recommends those free from it to use the following prophylactic pomade:

℞.—Boracic acid ointment } . . āā ℥ij.
Eucalyptus ointment }
Oil of cloves . . . . ℥ss.
Oil of cocoanut, q. s. to make . ℥ij.—M.

This preparation constitutes a most elegant pomade and entirely prevents inoculation. It should also be used on those parts of the patient's head where the disease has not reached.

In treating ringworm, Dr. Harrison does not advise the shaving of the head, but allows about a half-inch in length of the hair to remain. This, he says, gives a hold to the ointment. He prefers ointments to lotions, for the reason that ointments will be well rubbed in, while lotions will be but indifferently applied.

Treatment of Lupus.—DR. SCHÜTZ, in the *Therap. Monatsheft*, May, 1889, states that, having observed the beneficial effects of compression bandages in leg ulcers, he conceived the idea of applying a similar treatment in facial lupus where, after the latter has been scraped away, large granulating surfaces are left. His method is to apply a carbolized gutta-percha plaster containing mercury to the wound, and fixes it to its place with a thick coating of collodion. This plaster should be removed every six to twenty-four hours. The change of dressings should be performed as rapidly as possible, ether being used to dissolve the collodion. After the wound is fairly closed a plain dressing should only be applied for a few days; the cicatrix may then be rubbed down with powdered marble and soap and massage resorted to. The general health of the patient is also of great importance. A strong nutritious diet should be enforced; fresh air and gentle exercise also advised.

Antipyrin Hypodermically in Acute Articular Rheumatism.—A case of severe articular rheumatism, which, for seven weeks, had been treated by the remedies usually employed in such cases without avail, is reported by DR. H. AMON, in the *Centr. f. klin. Med.*, May 25, 1889, as having been completely cured by six-grain hypodermic injections of antipyrin. The remedy was subsequently employed in twenty other cases with equally gratifying results. Amon usually injected the drug deeply into the muscle and in the immediate vicinity of the affected joints; a bandage with considerable pressure was then applied. In one instance he observed a slight superficial gangrene of the skin to follow the injections. Very little pain was caused by their use.

Tape-worms in Children.—The following prescriptions will, according to the *Lyon Médical*, May 12, 1889, be found most effectual in cases of tapeworm occurring in children. Both are very agreeable to the taste, and are, therefore, easily administered:

I.

℞.—Oleoresin of aspidium	ʒj to ʒijss.
Peppermint water	f.ʒss.
Essence of anise	gtts. x.
Chamomile water	f.ʒj.
Syrup of sugar	f.ʒv.
Syrup of bitter orange-rind	f.ʒv.

II.

℞.—Oleoresin of aspidium	ʒj.
Calomel	6 grains.
Sugar	ʒij.
Gelatine	q. s.

Make into the consistency of jelly, and administer as a confection.

Thuya in the Palliative Treatment of Epithelioma of the Larynx.—At the meeting of the Société de Médecine Pratique of Paris, held on May 3d, DR. BARATOUX reported the results of the treatment of a number of tumors of the nose, throat, and larynx, with tincture of thuya (Gr. P.). The remedy has formerly been used in the treatment of growths on the genitals, and even in epithelioma of the neck of the womb. In growths of the first-named organs, the tincture speedily remedied the fetid breath, lessened the discharge and even caused a marked decrease in the size of the tumor. It was used in twelve cases in all, with equally good results. In one case, where extirpation of the larynx was impossible, it undoubtedly prolonged life for two years.

DUJARDIN-BEAUMETZ said, in the same meeting, that the tincture of thuya was valuable in growths of the skin, such as warts. RELIQUET stated that the tincture in twenty to thirty-drop doses was most valuable in vesical tumors when surgical interference was impracticable. Tincture of thuya given internally is a popular remedy for warts among the people of Brittany.—*Deutsche med. Wochenschrift*, May 23, 1889.

Calomel and Digitalis in Ascites.—In cases of ascites following cirrhosis of the liver, in which there are no other complications apart from cardiac affections, DR. SCHWASS, in the *Centralbl. f. klin. Med.*, May 25, 1889, advises the use of calomel and digitalis in the following formula:

℞.—Calomel	2 grains.
Digitalis	¼ grain.—M.

The above dose every three hours for a week.

The diuretic action of this combination is far greater than that of either drug singly and can also be tolerated longer and better than either drug alone.

The New Analgesic Exalgine.—Still another compound of apparently considerable medicinal value (if we may trust the statements) has been obtained from one of the products of the destructive distillation of coal-tar. It has been experimented with by several members of the Academy of Medicine, who have reported favorably; and in consequence of its marked analgesic properties it has received the name exalgine.

At the last meeting of the Société de Thérapeutique M. BARDET presented samples of this substance and made his report.

Exalgine represents chemically, methylacetanilide, $C_9H_{11}N.O = C_6H_5C_2H_3ONCH_3$. From acetanilide three methylic derivatives are obtained; one of these is the substance in question, and is designated by the name ortho-methylacetanilide. It presents itself in the form of fine needles or large white tablets, is little soluble in cold water, more soluble in warm water, and very soluble in spirit and water. Administered to animals (Paris) this substance acts energetically on the cerebro-spinal axis and speedily kills in the dose of forty-six centigrammes per kilogramme of the weight of the animal. It causes restlessness and trembling, and the respiratory muscles soon become paralyzed. In a less dose all sensibility to pain disappears, and the temperature of the body diminishes gradually.

The physiological effects of exalgine are very similar to those of antipyrin, although the former seems to act in a more marked manner than antipyrin on the sensibility, and less energetically on the heat centres.

The analgesic effects of exalgine are obtained by a full dose of seven grains; in some instances it may be necessary to repeat this dose in a few hours. The relief from pain is more prompt and more lasting than when antipyrin is given; this is emphatically the case in all forms of neuralgia, especially in the visceral neuralgias. So far no symptoms of gastric or intestinal irritation have been noted when exalgine has been given for its medicinal effects; its use has never been attended by cutaneous eruptions or by cyanosis.

Exalgine is eliminated by the urine, the excretion of which it seems to lessen in diabetic polyuria, at the same time that it diminishes the quantity of sugar in the urine. —*Boston Med. and Surg. Journ.*, June 6, 1889.

Injections of Iodoform in Cold Abscesses.—DR. BARKER, in the *Journal de Médecine de Paris*, May 19, 1889, states that he had frequently used injections of iodoform emulsion in the treatment of cold abscesses with marked success. The formula used by him is as follows:

℞.—Iodoform	10 parts.
Glycerine	70 "
Hot distilled water	20 " —M.

Grind up the iodoform with a few drops of alcohol and the glycerine, then add the water.

An Antiseptic Mouthwash.—DRS. GALIPPE and MALASEZ have found the following mouthwash most valuable as well as agreeable:

℞.—Alcohol	370 parts.
Carbolic acid	10 "
Thymol	5 "
Oil of peppermint	15 "
Tincture of anise	100 " —M.

This mixture, which may be colored with a little tincture of cochineal, should be used every morning and evening in conjunction with a weak solution of boric acid.—*Deutsche med. Wochenschr.*, May 23, 1889.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE . . . . . $5.00.

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JUNE 29, 1889.

THE ASSOCIATION MEETING.

FOR the first time in a quarter of a century the American Medical Association has met in a New England State, and for the first time in its history in the State of Rhode Island. While the gathering was not large in comparison with those of recent years—probably not over six hundred members were in attendance—yet all parts of the country were represented. The beautiful town of Newport was in attractive garb, the weather was perfect, and the arrangements by the Committee for the comfort and convenience of the members in all matters pertaining to the meeting were admirable.

The President's Address was an interesting exposition of the share in the advancement of medical knowledge taken by the American profession. The progress of medical education in this country and the marked improvement, within the last few years especially, in our means and methods were indicated, and the influence of such factors as improved preliminary education, a broader curriculum, and a higher standard, the endowment of colleges and the equipment of laboratories, rendered possible by the accumulation of wealth, were clearly traced. Reviewing our periodical literature as the exponent of professional culture and advance, Dr. Dawson pointed out that our oldest journal, *The American Journal of the Medical Sciences*, with its British contemporary, the *Lancet*, had for over half a century exercised a marked influence on medical progress, the value of which, he thought, could scarcely be overestimated. The Army Medical Museum and Library and our medical societies were also referred to as influential factors in professional culture. Turning, then, to the practical results, he cited anæsthesia, ovariotomy, and rapid lithotrity, with the operations devised by Sims, Sayre, Battey, and Emmet, as contributions to the relief of human suffering of which any nation might well be proud.

But Dr. Dawson did not confine himself to the roseate hue of medical progress; he strongly deprecated the provisions of some of the laws which have been passed of late years to regulate the practice of medicine, as conferring the seal of respectability upon any sham or pretender who held a diploma from any kind of college which might happen to possess a charter, and he took strong ground against the propriety of physicians sitting in State boards of health and the like with irregular practitioners.

In his peroration, Dr. Dawson made an eloquent plea for the maintenance of the National Association as a high and representative tribunal, the wisdom of whose decisions could always be relied upon, and to which all questions of general import can be referred.

One of the most remarkable evidences of the developmental growth of our profession is to be found in the large number of native works in every department of medicine which have emanated from the American press within the last two decades, which have almost completely supplanted the foreign text-books upon which we had heretofore depended. A reference to this Dr. Dawson might well have coupled with his allusion to the famous interrogatory of Sydney Smith, to which it is the reply. Not only is an edition of *The American Journal of the Medical Sciences* published in Great Britain simultaneously with its appearance in this country, but we constantly find in the London weeklies British booksellers advertising American text-books, some of which have been so highly esteemed as, also, to be translated into the principal foreign languages.

The Address in Medicine was a study of Benjamin Rush, as physician, philanthropist, and patriot, with a comparison of the therapeutic practice of his day with that which prevailed a century earlier in the time of Sydenham. The subject was aptly chosen, and by forcibly directing attention to the life and character of the greatest of American physicians, Dr.

Pepper ably furthered the efforts of the Association's Rush Monument Committee, of which Dr. Gihon, of the Navy, is chairman. The project for this monument was started at the meeting in Washington, in 1884, and, notwithstanding that the financial exhibit is now no more encouraging than that of many funds for similar purposes, yet it is confidently hoped that a sufficient sum may soon be subscribed to erect a memorial worthy of so distinguished a man. Public monuments have already been erected to all the great actors in the Revolution save Rush, a signer of the Declaration and a prominent and vigorous figure in the stirring events which followed and led up to the establishment of our national independence. Inasmuch as he was also America's greatest physician, it is eminently fitting that in these days of centennial reminiscences the medical profession should, to the honor of its own guild, erect at the Nation's capital a fitting monument to the memory of Rush.

The Address in Surgery made reference to some of the more important recent advances in this field of research, particularly to antisepticism, the surgery of the abdomen, brain and spine, tuberculosis, and cancer. While strongly endorsing the antiseptic method, and pointing out that the brilliant results of abdominal surgery have only been rendered possible by asepticism, Dr. Conner protested against that enthusiasm which sees in failure to obtain speedy recovery after injury or operation, evidence of "criminal neglect."

In reference to the two most fatal diseases, tuberculosis and cancer, he pointed out that while the recent discoveries in reference to tuberculosis had enlarged our knowledge of its surgical manifestations, and modified our treatment, in regard to cancer we still knew very little. We are aware of the importance of its early recognition and speedy removal, and of the uselessness, so far as ultimate recovery is concerned, of surgical interference after wide extension of the disease, but of its etiology we are still in ignorance. He concluded with the very practical recommendation that the Association should undertake a collective investigation to ascertain the frequency of carcinoma, its relation, if any, to geological formation; the age of appearance; the relative affection of parts; the influence of treatment; and the duration of life with and without operation. The Association could undertake no more useful investigation, and we hope that in a few years we may see fruitful results from this feasible and good suggestion.

The selection of Dr. E. M. Moore, of Rochester, for the presidency will be regarded throughout the country with universal satisfaction both for his personal worth and in recognition of his valuable contributions to practical surgery. It is the crowning honor of a long career devoted to the furtherance of the best interests of the profession and to the material advancement of surgical knowledge.

Nashville as the place of meeting has the merit of being central and accessible from all directions.

The attendance at this year's meeting was, without doubt, sensibly diminished by the limited accommodations afforded by the Newport hotels, and by the failure to secure the usual reduction in transportation rates. This, we are informed, was due not to any lack of courtesy on the part of the principal trunk lines, but entirely to the unwillingness of the Old Colony Railroad, which controls about all the approaches to Newport, to make any reduction until the last moment, when it was too late to notify the members and render the concession available. The largest meetings, too, experience has shown, have been held in the large cities on the main lines of travel, which have widely extended medical interests as well as the other substantial attractions that always insure a good attendance. The Newport meeting demonstrates that even an unusually good programme of scientific work will not fully counterbalance these more material advantages. Yet the meeting of 1889 will always be remembered as an extremely pleasant gathering, at which much excellent scientific work was accomplished.

EXCESSIVE GROWTH OF THE PROFESSION.

A LEADING article in the *Lancet* recently remarks upon the newly issued *Medical Register of Great Britain* for 1889, with somewhat gloomy forecast concerning the excessive growth of the medical profession during recent years. The editor holds that there is too great a rush into the profession on the part of young men. The new admissions to the *Register* in 1888 were 1184, while the known losses by death, retirement, and other causes were less than 600—the number of reported deaths being 511—giving an influx of qualified practitioners of about 600; the students' registration at the same time

amounting to 1986, or about 1400 over and above all losses. But of this invading column of 1986 would-be practitioners, about one-third, the figures of recent years show, will fall by the way before the end of the five years' study will have been reached. The *Lancet* expresses sorrow for the student and regret for the profession that so abnormal an increase of the ranks is annually threatened; apparently, its ideal of the growth of the fraternity would be one which would just about even up the losses that are sustained by death and disability.

But if the trans-Atlantic position be thus deplorable, what comfort is there in a contemplation of the situation in our own country? Here we have already a proportionate supply of doctors amounting to 120 to every 100,000 inhabitants, while in England there are only 64 in 100,000, and in Great Britain at large, a still less proportion. And the annual increment of medical graduates in this country is fully treble that of Great Britain; a recent summary of the Illinois State Board of Health states that 3,219 regular physicians were sent forth from the ninety-one schools of the better class during the session of 1887–8, and nearly 600 others non-regular. The output of the current year promises to be an ample one, to say the least; in four recent numbers of THE NEWS, the quota of graduates from twenty-four colleges east of the Rocky Mountains has been published, amounting to not less than 1,534, with forty or more regular institutions yet to be heard from. If the British outlook can be considered gloomy, how cheerless is the situation in this land of almost unrestricted production!

WE learn from the *Berliner klinische Wochenschrift* of June 3d, that the arrangements for the International Medical Congress in Berlin next year have been confided to Professors Virchow, von Bergmann, and Waldeyer. These gentlemen purpose not only to obtain the active coöperation of the profession of Berlin, but also of the whole of Germany. Invitations have already been extended to all German medical societies. The Congress will probably be opened on August 6, 1890.

DR. RICHARD J. HALL, Professor of Anatomy in the College of Physicians and Surgeons, New York, has resigned his chair by reason of ill-health. His successor to the professorship has not been elected, but Dr. George S. Huntington has been appointed to deliver the lectures in that branch at the session of 1889–90.

THE next meeting of the American Dermatological Association will be held at Boston, on Tuesday, Wednesday, and Thursday, September 17, 18, and 19, 1889.

BY the will of the late Stanton Blake, of Boston, the Massachusetts General Hospital receives a donation of $10,000. The work of the Hospital will be further amplified by an Act of the late Legislature, which sets apart the sum of $55,000 for the erection of an overflow hospital for epileptics at Baldwinsville.

DR. C. E. SIMMONS, who is suing the estate of the late Samuel J. Tilden for $143,350 for medical advice, figures up the sum, according to the *Boston Medical and Surgical Journal*, by charging $50 a visit for 2200 visits, and $50 a day for holding himself in readiness to devote his exclusive attention to Mr. Tilden.

The Lancet, of June 1st, says that according to intelligence received from the Governor of Madras, between one thousand and fifteen hundred deaths from cholera are now taking place weekly.

SOCIETY PROCEEDINGS.

AMERICAN MEDICAL ASSOCIATION.

Fortieth Annual Meeting, held at Newport, R. I., June 25, 26, 27, and 28, 1889.

(Specially reported for THE MEDICAL NEWS.)

(*By Telegraph.*)

GENERAL SESSION.

TUESDAY, JUNE 25TH.—FIRST DAY.

The General Session was called to order by Dr. H. R. Storer, of Newport, Chairman of the Committee of Arrangements, at 11.30 A.M., in the Music Hall, and the President, W. W. Dawson, M.D., of Cincinnati, took the chair.

The Rev. Thatcher Thayer then made the opening prayer.

The President extended an invitation to the ex-presidents of the Association and to all foreign visitors to occupy seats on the platform. This was responded to by Drs. N. S. Davis, J. M. Toner, and Wm. Brodie, ex-presidents.

Dr. Storer announced the death of Dr. F. H. Rehwinkel, of Chillicothe, O., Chairman of the Section of Dentistry, and of Dr. J. B. Hunter, of New York, who had promised to contribute a paper in the Section on Obstetrics.

Dr. Rives announced that letters of regret at being

unable to be present had been received from the President of the United States and his Cabinet; Sir James Grant and Sir Charles Tupper, of Canada; Dr. E. H. Gregory, of St. Louis, and Dr. H. I. Bowditch, ex-presidents of the Association.

Invitations were received from the commanding officer of Fort Adams, to witness a drill of the Light Battery; from Commander Higgins, of the Navy, in charge of the U. S. Training School; from Commander Woodward, of the U. S. Torpedo Station; from the Newport Hospital; from the Redwood Library; the Rev. Rabbi Mendez, of the Jewish Synagogue, the oldest in the State; from the Assistant Superintendent of the Third U. S. Life-saving District—each extending cordial welcome to all who desire to visit the various places of interest in their charge. Other entertainments were also announced by card.

Dr. Storer stated that he had placed on exhibition his collection of medical medals at the rooms of the Historical Society.

A letter of welcome was received from the Dean of Harvard Medical College to all who desired to visit that institution.

In view of the failure of the Committee of Arrangements to secure reduced railroad rates, Dr. Storer advised the Association hereafter to make it a duty of the Permanent Secretary to secure travelling facilities for the Association, or otherwise to retain some special officer for that purpose, suggesting the name of Dr. L. H. Mongomery, of Chicago.

On motion of Dr. J. C. Culbertson, of Cincinnati, the matter was referred for consideration to a committee of three to report to-morrow.

THE ADDRESS OF WELCOME

was then delivered by His Excellency, Herbert W. Ladd, Governor of Rhode Island.

Dr. James H. Eldredge read a greeting on behalf of the State Medical Society, of which he is one of the oldest members. In it he urged the admission into the Association of all physicians without regard to sex or school of practice.

THE PRESIDENT'S ADDRESS

was then read (see page 701).

The Session then adjourned.

WEDNESDAY, JUNE 26TH.—SECOND DAY.

The Association was called to order by the President at 10.30 A.M.

Rt. Rev. Thomas M. Clark, Bishop of Rhode Island, made the opening prayer.

Dr. Storer announced the several entertainments of the day, and repeated the invitations given the day previous.

The President announced the names of Dr. J. C. Culbertson, Dr. Schenck, and Dr. J. H. Musser as members of the Committee on Transportation.

The Permanent Secretary then announced the

NOMINATING COMMITTEE,

as follows:

Arkansas.—P. O. Hooper.
Colorado.—J. W. Graham.
Connecticut.—C. H. Bill.
District of Columbia.—D. W. C. Patterson.
Georgia.—J. B. S. Holmes.
Illinois.—J. S. Marshall.
Indiana.—G. J. Cook.
Iowa.—W. F. Peck.
Kansas.—J. E. Minney.
Kentucky.—J. M. Matthews.
Louisiana.—J. J. Bland.
Maine.—Frank Hitchcock.
Maryland.—John Morris.
Massachusetts.—J. N. Warren.
Michigan.—W. Brodie.
Missouri.—I. N. Love.
Minnesota.—J. H. Murphy.
Nebraska.— —— Carter.
New Jersey.—B. A. Watson.
New York.—E. D. Ferguson.
New Hampshire.— —— Hill.
Ohio.—W. S. Christopher.
Pennsylvania.—W. H. Parish.
Rhode Island.—George S. Collins.
Tennessee.—E. C. Savage.
Texas.— —— Van Gasken.
Vermont.—H. D. Holton.
West Virginia.—A. S. Stephen.
Virginia.—W. S. Robinson.
Wisconsin.—W. P. Galloway.
United States Army.—Major Smart.
United States Navy.—John L. Nielson.
United States Marine Hospital Service.—W. H. Long.
Utah.—W. Bascom.
New Mexico.—W. H. Ashby.

DR. WILLIAM PEPPER, of Philadelphia, now delivered

THE ADDRESS IN GENERAL MEDICINE.

It consisted almost wholly of a biographical sketch of Dr. Benjamin Rush. He spoke at length on his general good qualities as a man and patriot as well as a doctor, of his opposition to slavery, his support of and assistance to Franklin in the Revolutionary period and the formation of the government, his opposition to the abuse of alcoholic liquors, to the use of tobacco, his leadership in works of practical value, his standing as a literary man of the highest type, his advocacy of the advanced education of women, of public schools, etc. In every way Dr. Rush was a pioneer in the field of medical practice, and the history of American medicine practically begins with and was for a time the history of Dr. Rush.

DR. A. L. GIHON, of the Navy, then read his report of the

RUSH MONUMENT COMMITTEE.

The Committee regretted that they were unable to report progress. Indeed, they doubted if the project would be completed within their expectancy of human life. They called attention to the fact that the founders and leaders of every other profession and calling have been honored by fitting monuments and tributes. We join in hurrahing for the names of generals, politicians, etc., but forget the illustrious members of our own profession. It was believed a few years ago that the bare mention of the project would call forth spontaneous contributions of not less than one dollar from each of the forty thousand members of our profession. But the treasurer of the Committee now reports the receipt in

five years of only the first thousand. It is true that other great monuments have met with slow contributions. But of late there have been notable exceptions. In conclusion, the Committee begged to resign to the Association their appointment, in the hope that some other members may be found who shall discover some shorter way of securing the funds. They entreated the Society, however, never to abandon the project.

DR. HERRON moved that one member from each county society be appointed for the purpose of personally soliciting contributions to the Rush Monument fund. The motion was carried, as was also a motion that subscriptions be received immediately.

DR. GARCELON, of Maine, moved that the consideration of

AMENDMENTS TO THE CONSTITUTION

be made the first order of business tomorrow morning. The motion was lost.

The Secretary then read as the first amendment offered to "Strike out the last clause or paragraph of Section 7, relating to individually affixing names to the Constitution and regulations of this Association."

DR. N. S. DAVIS then read paragraph seven, explaining the intention of the proposed amendment. The amendment was unanimously adopted.

DR. SCOTT, of Ohio, moved that further action on the amendments be deferred until next year, in order to permit the Secretary to present the matter in an intelligible form.

DR. J. C. CULBERTSON moved that the preparation of the printed amendments be referred to the Board of Trustees of the *Journal*.

By unanimous vote the motion of Dr. Scott was tabled.

The SECRETARY then read as the second amendment offered that proposed by Dr. H. N. Moyer, of Ill., viz.:

"There shall be created a Section of Pharmacy and Materia Medica which shall have its own autonomy in like manner as the Section in Dental and Oral Surgery. Reputable members of State Pharmaceutical Associations shall be eligible as members of the same on presentation of credentials from their State Secretary, but shall have no voice in the general sessions of the Association. The Section of Surgery shall hereafter be denominated the Section of Surgery and Gynecology. There shall be created a Section of Anatomy and Physiology. The Section of Obstetrics and Diseases of Women shall be abolished. The Section of Diseases of Children shall hereafter be denominated the Section of Obstetrics and Pædiatrics. The Section of Dermatology and Syphilography shall hereafter be denominated the Section of Dermatology and Genito-urinary Diseases. The Section of Medical Jurisprudence shall hereafter be denominated the Section of Mental and Nervous Diseases. The Section of State Medicine shall hereafter be denominated the Section of State Medicine and Medical Jurisprudence. The Section of Practice of Medicine, Materia Medica, and Physiology shall hereafter be denominated the Section of Internal Medicine."

DR. N. S. DAVIS opposed the amendment as an effort to rehash all that has been done in the formation of Sections. He moved to postpone indefinitely all but the first paragraph.

DR. HERRON moved to amend the motion so as to postpone the entire amendment.

The entire matter was tabled by a vote of ninety-two to eight. A motion of Dr. Early, of Pennsylvania, to reconsider was unanimously laid on the table.

The Secretary then read the following amendment to Section V of the Constitution:

"The General Committee or Council shall be composed of *two members* from each State and Territorial Medical Society entitled to representation by delegates in the Association, and from the Medical Departments of the U. S. Army, Navy, and Marine-Hospital Service. They shall be chosen by the members registered and present at each annual meeting, from each State, Territory, and from the Medical Corps of the U. S. Army, Navy, and Marine-Hospital Service, acting separately, on the third day of each annual meeting; each delegation reporting the names of the members chosen to the Permanent Secretary of the Association on the same day, that they may be announced by him at the opening of the morning session of the fourth day. At the first election each delegation shall choose *two* members of the General Committee, one of whom shall serve *one* year and the other *two* years, and at each annual election thereafter one member shall be chosen to serve for two years, thus making the term of office of members of the General Committee *two* years. It shall be the duty of the General Committee, thus constituted, to organize by choosing annually a Chairman and Secretary, and such sub-committees as may be found necessary to facilitate the work that may be assigned to it; to meet annually at the place and on the day preceding each annual meeting, all the general officers of the Association (none of whom shall be members of its own body), the members of the Committee of Arrangements, the Committee on Necrology, seven members of the Judicial Council, and three members of the Board of Trustees for Publication for election by the Association; to recommend the place and time of holding the next annual meeting; and to consider and report upon all subjects that may be referred to it by vote of the Association. The presence of one-third of the whole number of members elected to the General Committee shall constitute a quorum for the transaction of business. If, at any annual meeting of the Association, it shall be found at the close of the general meeting of the first day that a quorum of the General Committee is not present, it shall be the duty of the President and Permanent Secretary to fill the vacancies in the Committee temporarily by selections from the lists of delegates registered as present from the States to which the vacancies belong."

Should this provision be adopted by the Association the Permanent Secretary should be authorized to substitute the name "General Committee" for "*Nominating Committee*" wherever the latter occurs in other parts of the Constitution and By-laws.

DR. EARLY moved that the consideration of the entire amendment be indefinitely postponed. The motion was lost by a vote of 24 to 48.

DR. N. S. DAVIS explained at length the intention of the amendment, at the same time giving the origin of it, and the necessity for such a change in the method of transacting the business of the Association.

The proposed amendment was strongly opposed by Drs. Larrabee, of Kentucky, Murdock, of Pennsylvania, Scott, of Ohio, Marshall, of Pennsylvania, and others; it was defended by Drs. Leartus Connor, of Michigan,

I. N. Quimby, of New Jersey, Jackson, of Pennsylvania. The amendment was lost.

DR. J. M. TONER reported that the sum collected at this meeeting for the

RUSH MONUMENT COMMITTEE

was $264.50.

A resolution referred from the Section of State Medicine was then read, to the effect that it is the duty of the United States and every other country to take measures for the removal of sources of infection within its borders.

THURSDAY, JUNE 27TH.—THIRD DAY.

The Association was called to order at ten o'clock by the President. Ex-presidents and foreign visitors were invited to seats on the platform, and Sir James Grant, of Ottowa, in a few remarks, acknowledged the courtesy.

DR. P. O. HOOPER, of Arkansas, presented the

REPORT OF THE TRUSTEES OF THE JOURNAL.

It gave a history of the six years of publication; stated that the finances of the Association had tripled, and that the *Journal* was the equal of the best in the country. The Editor's report showed that the weekly circulation was 4633 copies, out of which 4339 went to members of the Association. The total present edition was now 5000 copies weekly, and the year closed with the *Journal* free from debt. The report was accepted.

MEDICAL EDUCATION.

A resolution was presented from the American Social Science Association asking that a committee of three be appointed to consider the importance of a more thorough education of physicians for entering upon their medical studies, and of a more thorough regulation of the medical curriculum and of the placing of medical colleges under State supervision.

DR. P. S. CONNER then delivered

THE ADDRESS IN SURGERY.

(See page 708.)

THE TREASURER'S REPORT

showed a balance of $973.35, and the Auditing Committee reported that the accounts were correct.

THE REPORT OF THE NOMINATING COMMITTEE

was presented, as follows:

President.—E. M. Moore, of Rochester, N. Y.

Vice-Presidents.—J. W. Jackson, of Missouri; W. W. Kemble, of Minnesota; J. H. Warren, of Massachusetts; T. B. Evans, of Maryland.

Permanent Secretary.—Wm. B. Atkinson, of Philadelphia.

Treasurer.—R. J. Dunglison, of Philadelphia.

Librarian.—C. H. A. Kleinschmidt, of Washington, D. C.

Judicial Council.—N. S. Davis, of Chicago; J. H. Brown, of Kentucky; Wm. Brodie, of Michigan; R. C. Moore, of Nebraska; —— Gillespie, of Tennessee; T. A. Forster, of Maine, J. B. S. Holmes, of Georgia.

Trustees of the Journal.—T. O. Hooper, of Arkansas, Alonzo Garcelon, of Maine; I. N. Love, of St. Louis; W. W. Dawson, of Cincinnati.

Address in Medicine.—N. S. Davis, of Illinois.

Address in Surgery.—Hunter McGuire, of Richmond.

Address in State Medicine.—A. L. Carrol, of New York.

Committee to fill vacancies in the appointments to deliver General Addresses: Drs. William Brodie, J. H. Murphy, and I. G. Morris.

Place of next meeting, Nashville; *Time*, the third Tuesday in May.

Chairman of the Committee of Arrangements, W. T. Briggs, of Nashville.

Assistant Secretary, G. C. Savage, of Nashville.

The report was accepted and the nominees duly elected.

DR. J. C. CULBERTSON, from the Committee appointed to consider the question of

REDUCED RATES FOR TRANSPORTATION,

recommended that it shall be the duty of the Permanent Secretary to secure from railroads, steamboats, and other passenger traffic associations the lowest possible rates of fare to the place of meeting. After debate the resolution was adopted.

DR. WOODBURY, of Philadelphia, offered a resolution recommending the

ALTERATION OF THE PATENT LAWS,

so as to prevent discrimination in favor of foreign manufacturers of drugs. Adopted.

The Ophthalmological Section presented a resolution asking the Census Authorities to tabulate the

STATISTICS OF THE BLIND,

with the cause of blindness, so far as possible. Adopted.

The Section on State Medicine recommended the adoption of a resolution asking for

UNIFORMITY IN STATE MEDICAL LEGISLATION;

that a thorough preliminary examination, three courses of lectures, and an examination by the Board issuing a license be required. The license to practise be recorded in the office of the County Clerk, and that the Licensing Board be endowed with power to revoke a license on account of immoral conduct. Adopted.

The same Section also recommended that the Committee on Collective Investigation of Disease be discharged and that the Committee on Meteorology be continued with instructions to report to the Section on State Medicine at the next annual meeting.

DR. WOODBURY, of Philadelphia, moved that the members of the American Pharmaceutical Association be invited to seats on the platform, and that a committee be appointed to confer with the Association in reference to the creation of a Section of Pharmacy and Materia Medica in this Association, and to report on the second day of the next annual meeting.

The Committee on Dietetics reported progress and asked to be continued.

AMENDMENT TO THE CONSTITUTION.

DR. A. L. GIHON, of the U. S. Navy, presented an announcement changing the time of meeting from the first Tuesday to the first Wednesday in May or June.

THE PRESIDENT then introduced Sir James Grant, of Ottowa, who thanked the Association for its cordial welcome and kind treatment, and he expressed surprise and admiration at the vast amount of valuable work now being done in Medicine.

The Session then adjourned.

SECTIONS.

TUESDAY, JUNE 25TH.

SECTION OF MEDICINE.

DR. FREDERICK C. SHATTUCK, of Boston, Chairman.

THE CHAIRMAN, DR. SHATTUCK, opened the session with the following

INTRODUCTORY ADDRESS.

In obedience to the rule of the Association that the Chairman of each Section shall review the progress which the year has brought in those subjects which immediately concern his Section, he asked attention to a very brief consideration of a few of the large number of topics which might worthily find notice here.

The practice of medicine, materia medica, and physiology includes so much, the workers are so many, and the fruits of their labors are so varied and abundant that the difficulty of selection is itself an embarrassment.

The grass had scarcely grown on the grave of the treatment of pulmonary tuberculosis by gaseous enemata before another curative method was advocated by Weigert,[1] Halter,[2] and Krull,[3] a method which would seem at first sight to have claims to be called curative in that it is designed to remove the cause of the disease by destroying the bacilli *in situ*. We know that the development of this particular microbe is arrested at a temperature of 107° F.; and if, then, the intra-pulmonary temperature can be raised to or above this point and there maintained for a time the happiest results must follow. He confirmed the statements of the originators of this method as to the ability of patients to breathe with impunity air at a surprisingly high temperature. He, himself, had inhaled it at 320° F., and seen patients inhale it at 428° F. without notable inconvenience. Nearly six months ago, Dr. G. G. Sears, of Boston, began to practise inhalations of hot air on some patients in the House of the Good Samaritan. His results are now ready for publication, and it will suffice to say here that an apparatus was used devised by Mr. G. L. Kingsley of the Harvard Medical School, an apparatus which can be made by any coppersmith for $5—that patented by Weigert costs in this country $75—and that they are satisfied that the problem of intra-pulmonary direct germicidal action is still unsolved.

The pancreas, an organ the diseases of which have been until recently of pathological rather than clinical interest, is being dragged from obscurity. Senn's work on cysts of the pancreas is followed up by Fitz,[4] who has collected seventy cases of the several forms of acute inflammation of the organ, and subjected them to a rigid analysis which yields a notable increase to our knowledge. A frequent cause of acute pancreatitis seems to be the extension of an inflammation from the duodenum into the pancreatic duct and thence to the interstitial tissue of the organ; which tissue stands in such relation to the peritoneum, the retroperitoneal and retropancreatic fat tissues, as to permit the ready passage of bacteria, and thus account for the peritonitis and disseminated fat-necrosis so often resulting from pancreatic inflammation. Inflammation of this organ is doubtless much more common than has hitherto been generally supposed, and is not impossible of diagnosis. The affections with which it is most likely to be confounded, are irritant poisoning, perforating gastric or duodenal ulcer, perforation from gall-stones, and acute intestinal obstruction. The first three can be excluded by the history of the case, and the associated symptoms; the last by determining the patency of the large intestine through injection, by the seat of the pain and tenderness in the upper abdomen, and by the absence of marked tympanites. He trusted that he would be pardoned here for bringing in his own personal experience, which he did with the less hesitation, inasmuch as it is not especially to his credit. It was his lot during the past winter, to be one of six physicians and surgeons at a consultation; four of them considered the case as probably acute intestinal obstruction, one inclined to perforation, while Dr. Fitz alone held that it was acute pancreatitis, and advised against operation. Laparotomy was done, no obstruction was found, multiple fat-necrosis was seen in the omentum, and the autopsy revealed acute hemorrhagic pancreatitis.

Frerichs long ago noticed the frequency of atrophy of the pancreas in diabetes mellitus; and Lancereaux in a recent and important paper calls attention to the relation between these conditions, based on twenty cases which he has seen, with post-mortem verification in fourteen of these. Pancreatic diabetes, in contra-distinction from the other forms of the affection, is characterized by sudden onset, rapid course, and severity of symptoms with great emaciation. In two of the cases, by the way, epigastric colic led to the diagnosis of pancreatic calculus, and the autopsies brought justification.

He alluded to the experiments of Pavloff and Smirnoff,[1] which show that in rabbits whose pancreatic ducts have been ligated, regeneration of the gland may take place after a new and spontaneous communication with the intestine has been formed.

The much-vexed question as to the nature of diabetic coma, with the indications for the liability of its occurrence in any particular case, and the means for its relief, are ably considered by Kirstein,[2] who details the steps through which our present knowledge has been attained. In certain cases of diabetes the organism seems to have lost the power of burning the fatty acids, largely β oxy-butyric acid, to their normal end-products. These cases are characterized by a large increase in the amount of ammonia in the urine, rather than by any striking symptoms or complex of symptoms, and these are the cases in which coma is to be dreaded; this form of coma being the result of the formation of larger amounts of free acids than can be neutralized by the ammonia which the organism is capable of supplying, the consequent abstraction from the blood of the fixed alkalies, and thus toxæmia.

The quantitative estimation of ammonia in the urine of diabetics is, consequently, of great importance therapeutically as well as for prognosis; but, unfortunately, a method for this estimation, readily applicable to clinical purposes, is still lacking. When this large excess of

[2] Deutsch med. Wochenschrift, April 11, 1889.

ammonia is found, the indications are to restrict the acid rather than the sugar-forming foods—meats, for instance—and to give alkalies freely. On the advent of the peculiar dyspnœa, which is apt to be the first symptom of coma, alkaline intravenous injection is to be practised, as has already been done in a small number of cases, Minkowski alone having saved his patient.

The diseases of the blood have been studied by Graeber, Hunter, and others. According to Graeber,[1] anæmia, chlorosis, and pernicious anæmia are distinguishable from one another by a count of the red corpuscles and an hæmoglobin estimation. Hunter[2] argues to show that pernicious anæmia is an entity, pathological and clinical; depends on increased blood destruction, probably in the liver; and is to be differentiated from all grave anæmias, as, for instance, those of cancer and intestinal parasites, as well as from all other primary anæmias, by the greatly increased amount of blood-pigment, responding to the micro-chemical tests for iron, found in the liver in this affection. The spleen contains no such excess of iron as does the liver, and, in the latter organ, the seat of the pigment is chiefly the outer portions and cells of the lobules, not the capillaries, a fact which goes to show that the blood destruction takes place in the liver itself, the pigment entering the cells in soluble form—hæmoglobin—and there undergoing conversion into albuminate of iron. In all cases where the blood destruction takes place elsewhere than in the liver, and pigment is deposited in that organ, it accumulates in and about the capillaries.

A paper of MacMunn,[3] of Wolverhampton, on "Addison's Disease," is noteworthy. He has studied the adrenals and urine of patients with this disease, spectroscopically; and, reviewing our knowledge of the subject, concludes that the function of the adrenal bodies is the removal from the circulation of worn-out pigments and their accompanying proteids. "When the adrenals are diseased these effete pigments and effete proteids circulate in the blood; the former, or their incomplete metabolites, producing pigmentation of the skin and mucous membrane, and appearing often in the urine as urohæmatoporphyrin; the latter producing toxic effects and leading to further deterioration of the blood with its consequences."

At the meeting in Cincinatti last year, a discussion took place on the modern methods of diagnosis in diseases of the stomach; and high hopes were expressed that by the examination of the gastric contents an ease and certainty of diagnosis in these affections were almost within our reach comparable to that which urinary analysis yields in renal diseases. The more carefully the question is studied the greater is the demand for yet further study, and the more clearly does the necessity appear for the exercise of great caution in the formation of definite conclusions at present. In the first place, it is now seen that the only single test for free hydrochloric acid which has a real clinical value, is the phloroglucin-vanillin; the tropaeolin, congo-red, methyl-violet, and other tests, either reacting to other acids or acid salts, or being often prevented from reacting by albuminoids, even when free hydrochloric acid is present. Secondly, it gradually appears that it is not safe to base a diagnosis of gastric cancer or even the persistent absence of this acid from the gastric contents withdrawn an hour after a test meal. Such absence is indicative of notable impairment of the functional activity of the mucous membrane, as from a severe catarrhal condition; or of extensive destruction of the secretory glands of the stomach, largely irrespective of the cause of the destruction. Thus, in a case of cancer sharply localized and unaccompanied by catarrh to any marked degree, free hydrochloric acid may be found in sufficient amount until the cachexia is well advanced. On the other hand, in severe but simple catarrh, especially if attended by the formation of much mucus; in atrophy of the gastric tubules; in amyloid disease of the organ; after strong caustics have done their work; even in certain cases of impaired innervation; no free hydrochloric acid may be detected, though sought for repeatedly with the utmost skill, and the aid of every appliance and reagent.

It also appears that hyperacidity, though a frequent, is by no means a constant, accompaniment of peptic ulcer. Indeed, it is impressed upon us that the pathology of an organ which varies so widely physiologically in the same individual within such short periods of time is a very complicated thing, and the lesson is again enforced that it is not in pathognomonic signs, but in careful weighing of each piece of evidence, and in the painstaking collocation of them all, that accurate diagnosis is to be attained.

During the past year the internal antipyretics have continued to seek their level. It is seen that they exert no curative influence on specific febrile processes; and, as we recognize more and more clearly that even continued fever is not productive of the changes in the parenchymatous organ with which we credited it of late years, but that the danger of these processes lies rather in the effects of toxic alkaloids on the nervous centres than in temperature elevation, as we recognize this fact, we appreciate how irrational it is to address our therapeusis chiefly to pyrexia. When the fever is in itself productive of discomfort to the patient, internal antipyretics are useful; but the indications seem to me, at least, strong that the antineuralgic and analgesic will survive the antipyretic application of this class of drugs.

On the other hand, it seems probable that the cold bath treatment of continued, and especially of typhoid fever, must be adopted and conscientiously carried out in this country. As the principles of Brand's methods gain headway in France, a country not prejudiced in favor of German leadership; as Brand's results are confirmed by other observers and in other countries; and in the face of such statistics as are put into our language by H. C. Wood,[1] Wilson,[2] and Baruch;[3] it is difficult to see how a people who pride themselves on wealth, general intelligence, and practical qualities, can be longer deterred by scepticism, or motives of convenience and economy, from the adoption of a method of treatment which reduces the mortality of typhoid fever to three per cent.

The hypnotics sulphonal and amylene hydrate have come into more general use, and prove themselves to be

[2] Annual of the Med. Sciences, 1889, vol. i.

[3] New York Medical Record, 1889, vol. i. p. 434.

valuable additions to our list of remedies of this class. Unpleasant effects seem rare, while the slow absorption of the one and the rapid action of the other give each a place.

The treatment of locomotor ataxia by suspension (accidentally hit upon by Motchoukowsky, of Odessa, who was struck by the benefit derived by a tabetic patient, also suffering from spinal curvature, after the suspension required in applying a plaster jacket) has spread with great rapidity, and is being thoroughly tested in this, as well as in other countries. It is still too early to determine how useful it will prove to an unfortunate class of patients.

Morton Prince[1] was led by his duties as examiner of applicants for the Boston Fire Department, and by the frequency with which he heard temporary murmurs in vigorous men, to a study of their mode of origin. It has been believed for some years that in debilitated states leakage may take place through the mitral valve, the curtains of which are not tightly closed by reason of the insufficient force of the ventricular contraction. It will be at once appreciated that Prince's cases were the reverse of debilitated; and his ingenious explanation of the murmur heard in them is that, under conditions of great excitement, such as many of the applicants presented, the valve may be forced by ventricular contractions of a power disproportioned to the resistance of the valve. It is not easy to detect a flaw in his argument, and it seems as if he had made an important addition to our knowledge.

To sum up the results of the year, it may be stated that it has been one of real, though not of brilliant progress. Knowledge has been advanced almost all along the line, more in some parts than in others; bacteriology in its broad sense, including the chemical poisons generated by or accompanying the microbes as well as the identification and life-history of the organisms, offering an enormous field for patient research.

One fact seems to stand out in strong relief; namely, that our countrymen are on the high road leading to the attainment of a reputation for scientific research equal to that which they have long enjoyed in the more immediately practical branches of medicine and surgery.

The future glows with a promise which the achievements of the past assure us will be realized; and it is the part of each one of us, if he cannot discover, at least to do all that in him lies, to make the highest and best use of the discoveries of others more gifted than himself.

DR. CHARLES G. STOCKTON, of Buffalo, N. Y., then read a paper entitled

ON THE PASSAGE OF PORTAL BLOOD INTO THE GENERAL CIRCULATION, AND ITS PROBABLE RELATION TO TOXÆMIA.

The claim was made, first, that inosculations between the portal and the general systemic veins occur normally to a certain extent in all mammals; that as anomalous conditions these intercommunications may be extensive; that as a result of obstructive liver disease, or peri-hepatitis, new anastomoses may be set up. Next, it is claimed that the blood of the portal vein is toxic, at times extremely so. And it is held that toxæmia is prevented, in ordinary conditions, by reason of the lower blood pressure in the portal than in the general venous circulation.

When the portal circle is obstructed, portal blood enters the systemic veins without filtering through the liver, thus inducing toxæmia.

This would prove more disastrous than it does, but for the action of the blood upon the substances which are carried into the circulation. The blood having the property, when in health, of purifying itself to a certain extent, serious toxæmia does not often follow until the integrity—resistance—of the blood is diminished by long effort, or by disease; and then toxicity is made evident by symptoms.

In this connection reference is made to the coma of cirrhosis, to propeptonuria, glycosuria, and certain cachexiæ. The low pressure in the portal vein is proved by experiments of Prof. Julius Pohlman upon the lower animals.

DR. OSLER, of Baltimore, thought that the point referred to by Dr. Stockton is one of serious import. He was not sure, however, but that it is only partially true. He doubted whether the question thus received its solution. He believed that the collateral circulation is a constancy. This must meet the blocking up of the channels. The same condition obtains as in narrowing of a valve of the heart. Every one has found in post-mortem examinations extreme cirrhosis of the liver without a single symptom during life, and yet in such instances a great proportion of the portal blood passed into the general circulation. Furthermore, in cases of fibroid obliteration of portal vessels, the portal blood for years passes through the circulation.

DR. TREMAINE, of U. S. A., thought that the essayist had made a mistake in regard to the portal circulation. It is part of the venous circulation only interposing the liver. The purpose for which the venous blood passes through the liver is not perfectly understood. He would rather explain the results by a defect on the part of the action of the cells, whose office it is to eliminate the toxic elements.

DR. J. H. MUSSER, of Philadelphia, congratulated Dr. Stockton on the very ingenious arguments which he produced to maintain his thesis. The question, however, obtains so much of a physiological aspect that he felt quite incompetent to discuss it. Clinically he had never seen any cases of hepatic coma that could not be explained either by cholæmia, by uræmia, or by toxæmia due to the loss of function of the liver. This, of course, is only his personal experience. He would state that in all cases of hepatic coma there was either pneumonia or active congestion of the lungs, or some other inflammatory condition, however so small, but sufficient to overthrow the balance of the economy, and hence disturb the functions which destroy any deleterious matter in the blood.

DR. H. A. HARE said that he thought that perhaps Dr. Stockton had lost sight of the more recent studies of Schiff and Lautenbach—viz., that any capillary network is capable of rendering blood containing toxic substances innocuous. The lungs, for example, are similarly destructive agents. Capillaries are oxidizing agents, just as a shallow, pebbly brook is an oxidizing agent. That oxidization does occur is proved by the high temperature of the blood leaving the liver. Further, all peptones are

[1] N. Y. Med. Record, 1889, i. p. 421. Boston Med. and Surg. Journal, 1889, p. 109 *et seq.*

not poisonous, but it is rather the para-peptone or hemi-albumose which are abnormally absorbed and cause toxæmia. Peptones are normally absorbed, and predigested food by the rectum ought to cause toxæmia if all peptones were poisonous. Again, the argument of Dr. Stockton is faulty, since the inosculations are constant and the toxæmia is rare.

DR. LYSTER, of Detroit, stated that his attention had been directed more particularly to two cases of hypertrophic cirrhosis now under his own treatment, in whom attacks of fever occur whenever errors of digestion take place. This febrile movement he attributed to ferments or ptomaines, owing largely to the inferior quality of the bile and its lessened alkalinity.

While physiologists declare that the mercurial preparations do not promote the secretion of bile, yet it is very true that there are no preparations which are more valuable in the treatment of these cases. He is accustomed to combine the mercurial, whether hydrargyri chloridi mite or the liquor hydrargyri chloridi, with alkalies, either soda or potassa salts. He is inclined to believe with M. Dujardin-Beaumetz, that the value of mercurials is due rather to their antiseptic properties than to any specific quality. The theory of antisepsis will fully account for the great therapeutic value that clinicians find in opposition to the views of pure physiologists. The liquor hydrargyri bichloridi with bicarb potassæ, the equivalent of the seventy-fifth or eightieth of a grain of the bichloride, may be given three times daily, after meals, for several days at a time. We have in the portal circulation an impairment of the digestive fluids absorbed from the intestinal tract from the presence of the alkalies and the mercurials, and we escape the toxæmic influence on the systemic circulation which we would otherwise have frequently occurring. Cases where a comparatively large portion of the liver cells had become disintegrated in any of the forms of cirrhosis, and particularly in those cases of hypertrophic cirrhosis without dropsy and marked enlargement of the spleen, will be guided and aided along a comparatively safe path for a considerable period by these methods, even where severe hematemesis and slight attacks of paresis have occurred.

DR. CRONYN stated that Dr. Stockton's paper was very suggestive, that the coma in cirrhosis of the liver is due to the presence in the blood of some poison due to its state, consequent upon the arrest of the normal change which blood undergoes in the liver; we know that when the hepatic veins are lessened in their size derangement of their function alters the character of the bile, which, being absorbed in the form of cholesterin, brings about coma, and which he has been in the habit of calling cholestinuria, a name and condition due to the discovery of Dr. Flint, Jr. The contracted condition of the veins in the liver referred to, of course increases the size of the portal and the activity of the collateral circulation; it is therefore a matter of much interest to ascertain to what extent the intercommunicating veins may be the media of the toxæmic effects so frequently seen, especially in obstinate disease of the liver.

DR. STOCKTON felt much gratification over the discussion to which this paper has given rise. He did not consider that the criticisms in the main were contrary to the claims made in the paper. Notwithstanding the late investigations mentioned by Dr. Hare, the fact remains that peptones disappear in the blood without passing through a capillary network. The claim made that the blood pressure in the portal vein is lower than in the systemic veins, thus making a protection to the systemic circulation, was not spoken of. This should be explained. When the portal pressure becomes the higher, toxic conditions appear; and but for the action of other organs than the liver, and of the blood to purify itself, more conspicuous symptoms would occur. When the resistance of the blood fails then toxic symptoms do occur.

DR. J. H. MUSSER, of Philadelphia, read a paper on

SOME CLINICAL ASPECTS OF VOMITING.

He first called attention to the mechanism of vomiting, showing it was a reflex act due to excitation of a vomiting centre situated in the medulla, in intimate relation to the respiratory centre. Motor influences are transmitted from the centre to the abdominal and thoracic muscles, to the œsophagus and cardia, causing its relaxation, and to the pyloric end of the stomach, causing its closure. Excitation of this centre is made by impulses derived by afferent nerves from various organs of the body. It was shown that the vomiting may be toxic in origin, may be from organic change about the centre, as tumor, abscess, etc. And lastly, it is reflex from affections of various organs, all of which were detailed.

Attention was called to morning vomiting and other causes than those usually mentioned were detailed, as in sewer-gas poisoning, of vomiting due to subacute naso-pharyngeal catarrh and to ovarian and uterine vomiting, etc.

Some special clinical aspects of vomiting were then detailed, and it was insisted upon that in affections of various organs vomiting may for some time be the only marked symptom.

Regarding the relation of this symptom to cerebra hemorrhage the following conclusions were presented:

1. That sudden vomiting, occurring in the aged, painless, with or without nausea, with no evidence of indigestion or acute gastritis, the ejecta composed of mucus or watery fluid, is often one of the first symptoms of cerebral hemorrhage.

2. Such vomiting is not attended with the usual symptoms of relaxation, but with the sthenic phenomena which usually attend apoplexy.

3. If the usual collapse symptoms occur in a person of this age, the vomiting is now likely to be of uræmic origin.

4. If the respiration is altered in rhythm or is of normal frequency or slowed, because of the intimate relation of the centre for vomiting and the pneumogastric centre, the cause is doubtless a central hemorrhage. Hurried breathing attends the acute vomiting of other causes.

5. The occurrence of vertigo is not of special significance.

6. The prognosis is very grave in such cases.

Habit-vomiting, so-called, was then described.

DR. STOCKTON stated that without doubt vomiting due to naso pharyngeal catarrh occurs, and that if the stomach be carefully examined evidences of chronic gastritis will be found.

DR. I. E. ATKINSON, of Baltimore, then read a paper on

SOME OF THE RARER AND GRAVER FORMS OF CINCHONISM.

This paper treated of blindness, deafness, and general poisoning from the use of excessive doses of cinchona preparations, and was intended to show that the lavish administration of these remedies so frequently resorted to is not justifiable on account of the dangers entailed. The writer had collected more than fifty recorded cases of quinine amaurosis and showed that impairment of vision is probably much more often produced in this manner than is generally believed. Usually blindness only follows excessive doses, but definite results cannot always be attributed to definite doses, and blindness has been known to follow as small a dose as twelve grains. It may develop slowly or, as is usual, suddenly. The duration of total blindness may be from a few hours to many weeks. It is never permanent. Perfect vision, however, is never recovered. Careful observation has shown that the symptoms are characteristic and pretty constant. They are: 1. Transitory blindness, complete or incomplete. 2. Color-blindness. The color sense usually is restored ultimately. 3. Wide dilatation of the pupil, which is irresponsive to light. 4. Pallor of the optic disks and extreme diminution of the retinal vessels. 5. Contraction of the visual field. This never entirely disappears. Impairment of hearing with tinnitus is almost always present, but rarely lasts more than twenty-four hours. A number of variations from the type are noted. Idiosyncrasy undoubtedly plays an important part in the development of these symptoms. The pathogenesis of quinine amaurosis is not understood. The effect is probably a local one exerted upon the blood-vessels of the part. The dose competent to produce blindness varies greatly. Though blindness probably always results when the dose has been lethal, as much as one ounce failing to produce general poisoning has been known not to affect vision. In a number of cases patients have become blind after thirty to sixty grains given within a few hours.

Complete permanent deafness has never been known to follow the use of quinine, and permanent impairment of hearing from the same cause is very uncommon, not so uncommon, however, as is generally supposed; Roosa, Burnett, Greene, and others, have given abundant reasons for their belief that permanent partial deafness may occur. In these cases, however, a decided hyperæmia of the auditory apparatus is produced. Experiments of Kirschner, Roosa, and others, upon animals are quoted as corroborative.

General poisoning from cinchona preparations is rarely fatal. Baldion reported a death from twenty grains to a child, six years old, given in forty-eight hours. Deaths have also followed the administration of one hundred grains given in two days, and of one hundred and twenty grains in doses of five grains repeated every hour. A number of cases of alarming symptoms following not excessively large doses are given. In more severe cases the patient's condition may border upon collapse. There will be extreme prostration, with or without loss of consciousness, or coma, lowered temperature, gradual weakening of the pulse and respiration, chilling of the entire surface, copious cold sweats, deafness, dilatation and immobility of the pupils, blindness, lividity. Convulsions have been reported in a goodly number of cases. The exact nature of these convulsions has not been determined. Experiments upon animals by Baldion, Rochefontaine, Chirone and Cusci, Soulier, and others, show that quinine has a special convulsivant action. Brunton has also shown that convulsions may precede death, as a result of asphyxia.

DR. LYSTER, of Detroit, remarked regarding the use of quinine in large doses, that he quite agreed with the speaker who preceded him, that only such portion of the dose as was required to neutralize the malarial intoxication was appropriated, any excess of dose was eliminated from the system usually without any markedly injurious effect. The hypodermatic use of the quinine should be made in suspected cases of the congestive or malignant variety in regions where such cases were met with.

DR. ROBERT T. EDES, of Washington, then read a paper on

HYDRONEPHROSIS AND RENAL ATROPHY; ESPECIALLY AS RESULTING FROM FUNCTIONAL DISTURBANCES OF MICTURITION.

The ordinarily recognized mechanical causes of hydronephrosis were stated. Systematic authors admit that there are cases not explicable by any of these causes. Two cases were reported. I. A boy with frequent micturition but probable retention of urine, who presented symptoms of interstitial nephritis, and was found, after death, to have a large bladder, dilated ureters, atrophied kidneys, and hypertrophied heart; no mechanical obstacle being present. II. A little girl with albumin, casts, and pus in the copious, light urine, was noticed to have some difficulty in micturition. After dilatation of the urethra, the casts soon disappeared and later the albumin. The back pressure of urine necessary to produce moderate hydronephrosis with renal atrophy is not great. The bladder is a portion of the apparatus necessary for the discharge of the urine, and is not to be regarded simply as a passive reservoir. In order that it may perform its function properly a certain balance between the nervo-muscular apparatus promoting the discharges (detrusor urinæ) and that restraining it (sphincter vesicæ) is necessary. If this balance is disturbed either by paralysis of the detrusor or by spasm of the sphincter, pressure is thrown back toward the kidneys and dilatation of the passages takes place, followed by renal irritation and destruction of the parenchyma. In the constantly recurring spasmodic action of the bladder in cystitis, with the consequent exaggeration of the intravesical pressure, the same thing may occur, with this modification, that the urine which is backed up, being mingled with inflammatory products, the result is a pyonephrosis, rather than a hydronephrosis.

It is suggested that some cases of interstitial nephritis in the young, even when accompanied by hypertrophy of the heart, and not differing greatly in symptoms from the disease which is more familiar in persons in middle life, may have a local origin in unrecognized cases of this kind rather than the constitutional changes so prominent in the etiology of the Bright's disease of later years. A few cases are to be found in medical literature bearing on the subject of the paper.

SECTION OF SURGERY.

DR. N. P. DANDRIDGE, of Cincinnati, Chairman.

THE CHAIRMAN in his

INTRODUCTORY ADDRESS,

referred briefly to the remarkable advances that have been made in the treatment of fractures, displacements, and diseases of the spine. In connection with Pott's disease he reported the case of a child two years paralyzed, in which entire recovery, now continued four years, ensued upon careful restoration of the continuity of the cord. The various ways in which fracture may produce pressure upon the cord with consequent paralysis were considered. Operative interference must be considered first in regard to the advisability of immediate active efforts at relief.

He then reported five cases which had recently come under his observation. In some of them the application of a plaster jacket was all that was required; in others, the spinous processes were removed by the trephine. He preferred suspension by hammock and the application of a plaster jacket. Sufficient suspension can be made and an anæsthetic can be safely used if desired. The method of using the hammock was explained. It is simple, and in only one case was any pain complained of. A case was reported in which marked improvement followed simple hammock suspension. Suspension as now practised, is, however, a method so new that we cannot now determine its value.

Early operative measures—resection—should not be too readily laid aside, and in any case in which all other methods have failed, it should be tried. Although he had made several operations he had not yet secured a complete recovery. Since, however, recovery has been almost complete in many cases, since some lives have been prolonged by it, and since the operation is not now one of very great difficulty, he strongly recommended its adoption.

DR. H. H. SMITH, of Philadelphia, read a paper entitled

CONCUSSION OF THE SPINE IN ITS MEDICO-LEGAL ASPECT.

In introducing the subject he briefly reviewed the history of the establishment of the liability of railroads and other corporations for injury in England. He also announced the status of the various States of our own country on the subject.

In all cases of alleged injury of the spine with compression or concussion, frauds are always to be suspected, since statistics show that three-fourths of such cases have been found of that character; a few illustrative cases were then reported.

Admitting the liability of a surgeon to be misled in his diagnosis, let us inquire if there is any violence capable of producing concussion and compression of the cord. This must as yet be admitted as possible. The force required to produce it is, however, greater than is generally supposed.

The neuropathic disturbances which frequently follow injuries may be due to a neurotic condition of the patient, inherited or acquired; in the latter instance frequently as a result of sexual excesses. Charcot pronounces these disturbances hysteria. The speaker, therefore, concluded that real spinal concussion from injury is exceedingly rare. It is always rapidly followed by muscle-wasting. Its development is prompt—a few hours or days—after the injury and not weeks after, when his mind has had time to brood upon it.

Illustrative of the prompt development of symptoms in cases of injury of the cord, several cases were reported with the results of autopsy and microscopic examination. The following conclusions were announced:

1. Concussion of the spine is no longer a matter of doubt but may sometimes occur as the result of various forms of violence, there being nothing peculiar in the application of the force to the body, as the result of derailment or collision of railroad trains.

2. The pathological changes noted in the molecular structure of the cord as the result of shaking, jarring, or so-called concussion of the cord, when attended by paralytic symptoms, may be due to hemorrhagic effusion or be shown post-mortem, in softening or localized or limited atrophy. In cases due to hemorrhage the symptoms may be improved by judicious treatment and permanent disability prevented.

3. The possibility of preëxisting neurasthenia, or hysteria, or fraud on the part of a claimant, should be carefully noted in forming a diagnosis in these cases.

4. As the question of permanent disability, justifying exemplary damages, is frequently raised in claims of the kind alluded to, it should be recollected in forming a prognosis that numerous cases are reported of recovery or marked improvement in a few weeks, and one in three years, even after the occurrence of paralysis.

5. No physician should go into court and swear that a plaintiff has had a concussion of the spinal cord or of its nerves, unless he has proved the disturbance of the normal functions of the cord, as shown in sensation or motion, or both, and that the symptoms appeared *soon* after the injury.

DR. H. JUDD, of Galesburg, Ill., followed with a paper on the same subject. The facts stated in this paper, he said, were drawn solely from his own experience as a surgeon, from cases resulting from or suggested to the patient by accidents; cases in which all objective signs of injury, if any ever existed, had passed away; cases involving the question of supposed or alleged concussion of the spine and which were under observation from a medico-legal aspect; cases in which compensation for personal injury was sought.

His excuse for reading a paper on these cases, he said, was the fact that the question of injury or disease of the spinal cord, if it can exist, is becoming a question of business interest to the surgeon. It is a condition which is frequently estimated in the currency of the country.

The essayist then based his estimate of these cases upon the symptoms which accompanied these injuries in the times which preceded the enactment of laws making corporations liable to the injured. We might, he said, permit these people who practise frauds upon corporations to go on and rob them, saying it was none of our affair, but it is our duty to endeavor to prevent it, since it only trains and encourages malingering and dishonesty. Several fraudulent cases were then reported.

In conclusion, he stated that he questioned the possibility of concussion of the spine.

DR. WILLIAM BRODIE stated that he believed that such a condition as concussion exists. He did not believe that a correct diagnosis could be arrived at in many cases, short of a jury trial. There is only one way to treat these cases, and that is, for the railway surgeon to tell the companies to settle at once, within twenty-four hours, if possible.

DR. B. A. WATSON, of Jersey City, thought that we are too apt to consider concussion of the spine the condition described by Mr. Erichsen. If any such condition in the spine analogous to concussion of the brain exists, it is exceedingly rare. If any rupture of the ligaments, with laceration of bloodvessels exists, it is too rare to be considered. No physician should testify to the existence of concussion of the spine in a case presenting no objective signs. From his own experiments he had concluded that most of these cases suffer from lacerations of visceral organs much more frequently than from concussion of the spine. Laceration of the lung with the production of infarction is very common; laceration of liver, spleen, kidney, and even rupture of bladder occur.

DR. MURPHY, of Minnesota, stated that he had been interested in this subject a great many years, but that he did not meet with the success reported in the paper of the Chairman. All of the six cases he had treated during the last winter with plaster and other methods died.

DR. PANCOAST, of Philadelphia, thought that it should be borne in mind that the people had rights to be protected, and that we should not yield too far in our desire to protect corporations from imposture. He thought the law is at fault in demanding to know whether there is a permanent injury. Men should be protected and recompensed for temporary injuries as well as for permanent conditions. He objected emphatically to the suggestion of a former speaker, that the ligaments may stretch. Ligaments, healthy or diseased, *never* stretch.

DR. PANCOAST moved that the discussion of the paper of the Chairman, Dr. Dandridge, be made the order of the day. The motion being carried, he spoke freely on the subject of the rupture of ligaments, claiming that it is due to the tearing of the fibrous connective tissue.

DR. MAURICE RICHARDSON, of Boston, then read a paper on the

SURGERY OF THE PERIPHERAL NERVES.

It consisted of a *résumé* of the operations that have been made on the peripheral nerves for various forms of neuralgia. The first operations described were those which had been performed upon the inferior dental nerve, with a view to its division, stretching of it, or its removal.

The treatment of neuralgia of the sciatic nerve by stretching of the nerve is not held in favor since it has had a fair trial. It should, however, in all probability be resorted to in cases of inveterate neuralgia of the nerve. From original investigations on the cadaver, he did not believe it possible to exert any traction on the spinal cord by traction on the sciatic. Traction on the nerves of the upper half of the body he believed was of no value whatever. Neurectomy he considered the proper and only efficient means for their relief.

The last subject discussed was nerve-suture, with a report of cases. In a large majority of cases union was perfect and function reëstablished. In no case, however, was there evidence of the union by first intention alleged by some. If a large piece of nerve has been lost, he preferred the introduction of catgut to that of nerve-fragment. Nerve-grafting was also referred to.

In conclusion, the essayist described the condition of nerve which he had found in nerves affected by neuralgia in which pain is complained of, as in the musculo-spiral, the median, the ulnar, in cases having an obscure history of traumatism.

DR. PANCOAST expressed surprise that the essayist had attributed to Mr. Victor Horsley the operation of exsection of a portion of nerve for neuralgia of the trigeminus. This operation was first performed, to the surprise of the profession, by his distinguished father, whose aim it was to remove as much as possible of the nerve, even endeavoring to withdraw a portion of it from within the oval foramen before dividing it. He performed the operation several times, as had also the speaker.

DR. DEAVER, of Philadelphia, complimented Dr. Richardson on his easy method of reaching the temporo-maxillary nerve, and coincided with him in his preference for neurectomy to stretching.

DR. W. O. ROBERTS, of Louisville, reported several cases of operation on the inferior dental nerve, with the dental engine.

DR. GORDON, of Portland, Me., reported a case in which repeated stretching of the sciatic nerves yielding only transitory relief, the anterior crural nerves were stretched with the result of apparent cure.

DR. BURNS reported two cases of excision of the superior maxillary nerve in one of which there had been subsequently removal of the inferior branch.

DR. RICHARDSON explained that his paper had nothing to do with Horsley, and did not claim any assertion like that referred to by Dr. Pancoast. As he had read only a small portion of his paper, he could readily understand any misunderstanding which had arisen in the discussion. In conclusion, he described the method, preferred by but not original with him, for removal of the infra-orbital nerve and some of the descending branches of Meckel's ganglion through the orbit.

SECTION OF OBSTETRICS AND DISEASES OF WOMEN.

W. H. WATHEN, M.D., of Louisville, Chairman.

DR. HORATIO R. STORER, of Newport, R. I., spoke of

THE MEDALS OF BENJAMIN RUSH, OBSTETRICIAN.

The paper called forcible attention to the fact that to Dr. Rush was due the first suggestion, or rather prophecy, of obstetrical anæsthesia. He quoted various passages from Rush's works which demonstrated that he was a skilful obstetrician. In the title of one of his papers he closely associates the pains of labor with its dangers, announces that they can both be lessened, recognizes that they are the potent cause of subsequent disease, and teaches their prevention. Particular attention was called to the following statement of Rush: "I have expressed a hope in another place that a medicine would be discovered that should suspend sensibility altogether, and leave irritability or the power of motion unimpaired, and thereby destroy labor pains altogether." The importance of this extraordinarily interesting passage seems to have been recognized only by Channing, Gaillard Thomas, and Faget of New Orleans. It was lost sight of entirely during the ether-chloroform controversy. Exhaustive research has been made by the author, aided by Dr. Toner, of Washington, which has resulted in failure to find any other reference to it, and similar want of success has followed the studies of Drs. Chadwick, Gaillard Thomas, and Mundé, to whom the author appealed as

those who were most familiar with modern obstetric literature.

Dr. Storer exhibited enlarged photographs of the two extremely rare medals of Rush which are in his collection, and expressed the hope that they would be of use in giving the correct features of the "American Sydenham" when his monument, undertaken by the Association, shall be raised, and that the paper itself might tend toward a better appreciation of the true merits of the man himself.

DR. W. W. POTTER, of Buffalo, read a

NOTE ON THE USE OF BORACIC ACID IN GYNECIC PRACTICE.

He first used boracic acid as a substitute for iodoform on account of the bad effect of the latter upon the hands. He found that boracic acid delayed decomposition of uterine and ovarian discharges, and that a tampon could be retained for a week without discomfort or annoyance when this antiseptic was used. In his experience it had also been of service in cases in which sterility existed, and he believed it exerted such chemical action upon the uterine secretions that fecundation became possible. He had also found it one of the best dressings for operative wounds of the female genitals.

INVERSION OF THE UTERUS; REDUCTION BY A NEW METHOD; EXHIBITION OF THE INSTRUMENT.

DR. H. O. MARCY, of Boston, said that inversion may be partial or entire, and is probably more frequent than is usually supposed, especially in the practice of midwives. The shock and hemorrhage attending the accident are usually severe, and it is not unusual for the patient to succumb within a very short time after the accident has occurred. Hence the principle that reduction should be accomplished as soon as possible, the patient being then kept upon her back, with the vagina tamponned for a sufficient period. The methods of reduction of Emmet, Noeggerath, and Thomas were described and commented upon. Spontaneous reduction could occur, but it was thought that it rarely did. The first systematic attempts at reduction were reported by Prof. J. T. White, of Buffalo, in 1858, Tyler Smith reporting his method in the same year. The method of Winey, of Boston, was thought to be sound in principle, and it had been successful in practice. Barnes's suggestion, that lateral incisions should be made in the cervix before attempts were made at reduction, was also a good one, and had been followed by good results. Thomas's method was once considered bold, though ingenious, but now that laparotomy is so frequently performed, it would be adopted with less hesitancy. It has been demonstrated, however, that it may be unsuccessful. The author's method was then described, the principle being that traction was applied to the cervix while an equal amount of pressure was applied to the fundus, the opposing forces harmonizing and quickly effecting reduction. The present perfected instrument was reached after a long series of experiments, and has been tried in one case, in which complete reduction was effected in twenty-six minutes. The method consists in passing four stout ligatures through the cervical tissue at equal distances from each other, and these are attached to two parallel rings or hooks upon the side of a long shaft, the hooks working in slots. At the end of the shaft is a hard-rubber cup which receives the fundus. The shaft contains a screw, which is worked by a nut at its lower extremity, the shaft being graded in pounds up to fifteen, according to the number of turns of the screw. As the screw is turned the cervix is dragged down, and at the same time the fundus is pushed upward and through it.

DR. JOSEPH PRICE, of Philadelphia, reported

A SERIES OF FIVE HUNDRED CASES OF CONFINEMENT IN A MATERNITY.

There had been no deaths and no septicæmia in this series, the institution in question being the Preston Retreat, in Philadelphia. Absolute cleanliness of person and surroundings, abundance of water, soap, and pure air were the means which had yielded such gratifying results. Of these cases fifty-two had been cases of instrumental delivery, many of the mothers having contracted pelves. There was one case of placenta prævia, three of twins, also several face and breech presentations.

DR. FRY, of Washington, read a paper on the

APPLICATION OF FORCEPS IN TRANSVERSE AND OBLIQUE POSITIONS OF THE HEAD, WITH A DESCRIPTION OF A NEW FORCEPS.

He had sought to obtain the views of many practitioners as to their method of using forceps, and had addressed them in a circular letter. This brought eighty-two responses, of which forty-two stated that the custom was to apply the instrument to the sides of the head; thirty-one others applied to the sides of the pelvis, and in the others the method was indifferent. The author's instrument was curved on the flat, and could be applied in either transverse or oblique positions to the bi-parietal diameter of the fœtal head. Many cases in which there was death or paralysis of the fœtus, were those in which the blades of the ordinary instrument were not at the sides of the pelvis, its pelvic curve being a source of injury when applied in the conjugate diameter. The posterior blade of the author's instrument has both a cephalic and a pelvic curve, the anterior has only the cephalic curve. The instrument has also a screw for the regulation of the compression and a traction rod which is attached to the anterior blade and aids in bringing the head down to the brim of the pelvis.

DR. WILLIAM S. STEWART, of Philadelphia, read a paper entitled

WHEN SHOULD THE OBSTETRICAL FORCEPS BE USED, AND WHAT FORM OF INSTRUMENT IS REQUIRED?

Such conditions as eclampsia, exhaustion, uterine inertia, large or impacted fœtal head, called for the use of obstetrical forceps. The membranes must also be ruptured, the os dilated and its lips retracted; there must be a knowledge of the position of the child, the bladder and bowels must be empty. It would seem to be self-evident that one should use that instrument with which he was most familiar or which he found most effective. An objection to the ordinary forceps with crossed handles was that, while it was easy of application for the first position, it was difficult or dangerous for the second. Hence the author's instrument, in which the handles are parallel and do not cross. It has also a second joint to the handles and hand-piece, the traction being entirely accomplished with the latter. The blades

may be those of the Simpson, or Hodge, or Wallace forceps. The traction and compression with the author's instrument are regulated by the resistance offered; also the principal joint in the handles is not fixed, so that there may be very complete adaptation of the head to the pelvis. Either blade can be applied first, and, in the author's opinion, the instrument insures greater safety to the mother and child than by customary means, and greater ease to the accoucheur.

SECTION OF DISEASES OF CHILDREN.

J. A. LARRABEE, M.D., of Louisville, Chairman.

DR. E. F. BRUSH, of Mt. Vernon, N. Y., read a paper on

COW'S MILK FOR INFANT FOOD.

The medical profession, he said, is agreed that nothing equals good cow's milk as a food for infants, and therefore it is to be regretted that attention has not been given by the profession to reforming the breed of cattle and the handling of milk rather than to artificial substitutes. In milk for infant feeding there should be considered (1) the variety of fats, (2) the amount of albuminoids, (3) of salts, (4) the handling of the milk, and (5) the health of the cow.

First. As regards the fats, the usual processes of chemical analysis lead to an underestimate of the fats in cow's milk, and that of these fats we have no late authoritative analysis, a neglect on the part of chemists which leaves us in doubt as to which of the fatty acids are the mischief-makers in milk. These fatty acids have more to do with the development of poisons than the albuminoids have and are the cause of digestive derangements. Second. The albuminoids vary considerably with the time or habit of extracting the milk, milk extracted every two hours not being likely to possess as much or as ripe albumen as that drawn off every twelve hours. In health the albuminoids are constant, but materially affected in disease. This affection is not surprising when we examine the mammary sources of milk, for then there are found inflammations, calculi, clots of fibrin, etc., while the gland is at the same time subject to infiltrations, tubercular deposits, and eruptive diseases. In all cases variations in the amount of albuminoids must be ascribed to sickness. Third. The salts also have not lately been determined by chemists and we do not know how constant the occurrence of these salts may be, though we can assert that they are influenced both by the health and the food of the animal. Hence the land on which a cow is pastured will indicate fairly what we may expect to find as salts. The nutritive value of the sugar is overestimated, as is shown by the milk of carnivorous animals. Condensed milk or concentrated sugar of milk is not to be recommended as an addition to milk, but cane sugar preferred. The chemist's ideal food is a failure and the idea that milk must contain such and such constituents in such and such proportions is a popular error. Fourth. The cow must be studied, "for milk is the scavenger of the cow's body," and if it will not nourish the infant she is sick or the milk badly handled. A faulty condition of the cow is indicated by alteration, the albuminoids, bad food by the loss of fats and salts, and bad handling by the ptomaines. The cow has an abnormally high temperature, her organs of generation are in unnatural activity and she is made a machine for producing milk. It is no wonder then that she is, as a rule, an unhealthy animal. Owing to the low price of milk the delicate animal is rarely fed properly, and the same cause compels the farmer to utilize every drop of milk, be the cow sick or well. Good food is the prime essential for producing good milk. Fifth. Milk is affected by its surroundings in the cow-house, and the method of getting rid of the odor thus acquired by saltpetre cannot be too severely censured, for the addition of the nitre united with the glycerides may produce poisons approximating to tyrotoxicon. No chemical substances should ever be added. Milk should not be beyond a few hours distance, for long travel must deteriorate milk. Light, like heat, hastens decomposition, therefore glass bottles should not be used. The milk ought not to be given to the infant warm, for then it coagulates like too-old milk. Sterilized milk may be employed if we abandon all hope of improving the quality of milk.

The remedies for these evils are a better cow, one not closely inbred, well-fed with good, sound food, and well attended to. The cheapness of milk is the reason why we have not better milk and the inferior milk suggests the use of substitutes. If the price of the latter were added to the price of such milk the extra money would enable the farmer to buy better cows and better food and improve the quality of his products. This he ought to be compelled to do. Let us not recommend patent baby foods, but good, high-priced milk, and then if any trouble arises lay the blame on the milkman. Dairies for supplying infants' food should be under strict sanitary supervision. Such an ideal dairy should consist of spayed cows.

(Dr. Bush was given a special vote of thanks for his valuable paper.)

DR. J. A. JEFFRIES, of Boston, said a large number of women cannot feed their babies and many will not; hence the necessity for a proper supply of cow's milk. It is important to obtain that with fat as near like the mother's as possible, that the proper adipose tissue may be deposited in the infant's body. Recent analyses show that both the fats and albuminoids vary with the condition of the mother. A child did badly: the mother's milk was found too high in albuminoids, and on dieting the mother the child recovered. Milk sugar is a valuable aliment and not so liable to fermentation as cane sugar. Where milk can be got to the child within three or four hours after drawing, sterilization is not so important, but when, as in cities, twelve or twenty-four hours must elapse, it should be sterilized immediately on being drawn, and then forwarded in sealed bottles.

DR. EARLY, of Pennsylvania, considered diseases of cattle a frequent source of contamination of milk and referred to his investigations of dairy farms near Philadelphia and Camden, where milk from animals sick with pleuro-pneumonia was supplied to consumers.

DR. SEARS, of Texas, doubted if disease was conveyed by milk; certainly not to adults.

DR. CHRISTOPHER, of Cincinnati, related the results of his inspection of dairy farms near Cincinnati. Cows fed on distillery slops were much handsomer in appearance than those properly fed, and their milk was richer in cream. They urinated almost constantly. He attributed this to their confinement setting up fatty tissue changes. There is a peculiar condition of the albumi-

noids in this milk leading to rapid decomposition. He did not agree with Dr. Brush that the fatty acids were the poisonous elements. Ptomaines are nitrogenous bodies and can only be formed from volatile fats. There is none. The fatty acids are sometimes volatile, but this does not interfere with chemical analysis.

DR. BRUSH, in closing the discussion, gave prominence to the points that living foods contain some element lacking in preserved foods. Condensed milk may be perfectly pure, but it has gone through a process that robs it of some nutritive quality, So with various artificial foods, chemically desirable. The distillery-stable cows are sleek-looking, but they are œdematous, not fatty. It is a fact of observation that the amount of fats and salts in cow's milk can be altered by feeding, but it is only disease that causes a variation in the albuminoids given by any individual animal.

WEDNESDAY, JUNE 26, 1889.

SECTION OF OBSTETRICS AND DISEASES OF WOMEN.

DR. W. H. WATHEN, of Louisville, read a paper on the

PATHOLOGY OF ECTOPIC PREGNANCY AND PELVIC HÆMATOCELE.

He based his argument upon the following premises, viz.:

1. The ovum is never impregnated in the uterine cavity, and the conjugation of the male and female elements must take place before or just after the ovum enters the tube.

2. Ectopic pregnancy is always primarily tubal, with the possible exception of ovarian pregnancy; the tube usually ruptures before the fourteenth week into the folds of the broad ligament or into the peritoneal cavity.

3. Abdominal pregnancy cannot occur except as a result of primary or secondary rupture, and if the villous or placental attachments are destroyed the ovum immediately dies, because it cannot form secondary attachments to other structures.

4. If, in rupture into the peritoneal cavity, the ovum retains villous or placental attachments, it may be possible, under certain conditions, for the pregnancy to continue, though this is not probable. If the amnion is ruptured in the early months, the embryo or fœtus will die.

5. So-called interstitial pregnancy does not always rupture into the peritoneal cavity, though it usually does.

6. If we define pelvic hæmatocele as an encysted or confined tumor formed of blood, then intraperitoneal hæmatocele is not possible.

Tait is almost alone in his belief that in normal pregnancy the conjugation of the two elements takes place in the uterus, and the author does not think his premises upon this subject are correct nor his conclusions logical. His assertion that the spermatozoids cannot pass out through the Fallopian tubes unless disease has destroyed the ciliated epithelium, is based upon no positive evidence and is contrary to what has been proven in observations upon the lower animals. The ciliated epithelium has no effect upon the movements of the spermatozoids, and their inherent power of movement is proven in those cases in which women have become pregnant with a nearly imperforate hymen, and with atresia vaginæ with only a small fistulous and diseased canal leading to the uterus. If the ovum is not impregnated before, or just after, it enters the tube, degenerative changes will destroy its vitality before it reaches the uterus. If, after impregnation has occurred, the surfaces of the endometrium were not in immediate contact, the ovum would gravitate to the lower segment of the uterus, causing placenta prævia, or else it would pass out into the vagina. The ovum cannot form villous attachments until it is held immovably in the maternal structures, and this is not possible, except in the tube or in the uterine cavity. The reports of ovarian pregnancy are numerous, but they seem to be based upon insufficient evidence. In none of them has ovarian stroma been found unless confined to one side of the sac, and this may easily be due to tubal pregnancy in which rupture has occurred into the folds of the broad ligament.

Parry's statistics of ovarian or abdominal pregnancy were all collected from imperfect or mutilated records made by men of no experience in microscopical and pathological research, and they are practically of no value as proof that pregnancy may primarily occur outside the tube. Ectopic pregnancy may occur at any point in the tube, from a short distance within the fimbriated extremity to the uterine cavity, and is caused by partial or complete closure of any part of the tube, which is usually the result of desquamative salpingitis. It is improbable that tubal pregnancy continues in any case until term, rupture usually occurring prior to the fourteenth week either into the folds of the broad ligament or into the peritoneal cavity. Primary intra-peritoneal pregnancy is impossible because the ovum cannot be held securely in any one place and form the necessary attachments. The ovum precipitated into the peritoneal cavity dies, therefore, for want of nutrition.

The placenta in extra-peritoneal pregnancy may attach itself to the uterus, omentum, intestines, pelvic and abdominal wall, etc., by stripping off and carrying before it a layer of peritoneum, and many such cases have been reported as abdominal pregnancies. In the latter months of pregnancy the ovum may possibly continue to develop in the abdomen after rupture of the amnion. In intestinal pregnancy there is *usually* rupture into the peritoneal cavity, but *not always* as Tait asserts.

Pelvic hæmatocele sustains such intimate relations to ectopic pregnancy that it is not easy to describe the pathology of the one without referring to the other. Pelvic hæmatocele is usually considered an encysted, intra- or extra-peritoneal blood tumor in the pelvis which may extend into the abdominal region. The author does not believe it possible for an accumulation of blood in the peritoneal cavity to become encapsulated so as to form a well-defined tumor in the pelvic or abdominal cavity. If it were possible to have encysted intra-peritoneal hæmatocele, why does it never occur after abdominal sections for the removal of a diseased tube, ovary, or uterus? Encysted hæmatocele may result from a sudden cessation of a pseudo-menstruation that sometimes follows laparotomy, but in such cases the blood is effused into the areolar tissue under the peritoneum, and not into the abdominal cavity. A blood tumor may extend above the pelvis, and even to the umbilicus, but this does not indicate that the hemorrhage has been into the peritoneal cavity. In intra-peritoneal hemorrhage no well-defined tumor can be

felt *per vaginam* or by abdominal palpation, while in extra-peritoneal hemorrhage an error in diagnosis is hardly possible. Intra-peritoneal hemorrhage is almost always caused by primary or secondary rupture of a tubal pregnancy, and the shock and other evidences of internal hemorrhage will usually point to the cause.

The treatment indicated is abdominal section and ligation of the bleeding vessels. Encysted hæmatocele may be caused by sudden metrostaxis of normal menstruation, or pseudo-menstruation following abdominal or pelvic operations, or by rupture of a tubal pregnancy into the folds of the broad ligament. The symptoms are sudden access of pain, faintness, accelerated pulse and, possibly, elevation of temperature. The tumor may not be felt above the pelvis, or there may be a well-defined, fluctuating tumor extending as high as the umbilicus. The diagnosis is less readily made if the case is not seen until some days after the hemorrhage has occurred. Extra-peritoneal hæmatocele usually results in speedy recovery, with suitable care and precautions, the blood being absorbed. Suppuration or rupture into the peritoneal cavity rarely occurs. Should there be symptoms indicating that either of these conditions has occurred, the abdomen should be opened, the cavity thoroughly cleansed, and a drainage tube introduced. If fluctuation is felt *per vaginam* the tumor should be entered through the vaginal vault, otherwise laparotomy should be performed.

DR. T. PARVIN, of Philadelphia, in a paper on

CASUISTRY IN OBSTETRICS,

said that questions of conscience must always be recurring in the course of the practice of obstetrics. It might be said that all law in all civilized lands is only casuistry. Among the questions of conscience which are proposed to the obstetrician for answer is that of Comte: If the object of pregnancy is the perpetuation of species, and cohabitation during pregnancy is a source of danger to the fœtus, should cohabitation be allowed? The author would answer this question decidedly in the negative, considering that it is improper, immoral, unjust, and injurious to both mother and fœtus. Another pertinent question was:

"Should a doctor inform his patients as to the means of preventing pregnancy, admitting that he had the knowledge?" The reply was, that such information would usually be unwise, for though there might be excuse for such information on the score of serious disease in the parents, or inability to protect and support children should they be born, such information was usually extensively disseminated, and its influence would be pernicious. The question as to the propriety of artificial miscarriage is also an important one, and the justifiability of the operation was recognized in such cases as those in which blindness would result from the continuation of the pregnancy.

Such operations as amputations of the pregnant uterus were considered justifiable in certain cases of great pelvic deformity, and the testimony of Tait in this matter gives weight to such an opinion. It must also be admitted that there are also cases in which embryotomy or craniotomy, or some other destructive operation, is not only justifiable but imperative in the interests of a parturient woman. This statement did not at all conflict with that which had reference to the usefulness of the Cæsarean section. The latter operation should be preferred to craniotomy in those cases in which the conjugate measured two inches or less.

DR. WILLIAM H. PARISH, of Philadelphia, then read a paper on

PELVIC ABSCESS IN THE FEMALE.

He believed that the existence of pus in the areolar tissue was rare compared with its existence in the pelvic cavity or the organs of the pelvis. He would divide pelvic abscess into three varieties: 1, areolar abscess; 2, intra-tubal and ovarian abscess; 3, intraperitoneal abscess. The first form is usually a sequel of labor, the latter having been severe and accompanied with more or less injury to the uterus, the cervix, the vagina, etc. Secondary areolar abscess may occur, however, from gonorrhœa, from hæmatoma, etc. He believed that so-called chronic cellulitis, without precedent inflammatory disease of the pelvic organs of some kind, did not exist. The second form usually involved both the tubes and the ovaries, and was more frequently seen than the first. Associated with this there might be a plastic inflammatory condition of the pelvic peritoneum. The term pyo-salpinx gave little idea of the extent of this form of pelvic abscess which was possible. Intra-tubal abscess was very frequently due to gonorrhœa, which frequently occurred in young married women, though it might not appear for some months after marriage. It might also come from various forms of traumatism, from septic infection other than gonorrhœa communicated from the uterus.

Septic salpingitis and ovaritis frequently occurred after abortion, in fact rather more frequently than areolar abscess. The careless use of uterine sounds and tents was also responsible for many cases of this condition. In treating either of these two forms of abscess a high degree of operative skill is requisite. Another requisite, in order to a successful issue, is perfect drainage. Aspiration of such cases is usually not advisable, and is fraught with danger. If there is bulging and fluctuation in the vagina, an incision through its wall is indicated. If by such incision an intra-tubal abscess is opened, it may be recognized by the fact that the walls of the abscess sac are smooth to the feel, and also do not collapse. In most cases it is quite inadvisable to operate through the rectum. In any case in which an incision is made, care should be taken to avoid pulsating vessels. Likewise, in placing a drainage-tube it must be provided that it does not come in contact with the wall of a large-sized bloodvessel. If the abscess involves the tube, the necessary treatment is laparotomy with removal of the diseased structures, and the insertion of a drainage-tube. Cases have been reported in which intra-tubal abscess has been cured by drainage through the uterus, but such cases are believed to be of very rare occurrence. The method of stretching the edges of the abscess-sac into the abdominal wall, as advocated by Tait, is not considered desirable for most cases.

The intra-peritoneal variety of pelvic abscess is that in which the pus is in the pelvic cavity. It is not as frequent as that which proceeds from diseased tubes. It may occur from the leakage of pus, from a pyo-salpinx into the peritoneal cavity, from a peritonitis, from lymphatic inflammatory conditions, from initiating ligatures after abdominal section, etc. The quantity of pus in the

abscess may be small or it may be very large. In one of the author's cases the quantity was two gallons. In all cases of this variety there should be early operation. Should a fistulous tract result it not infrequently indicates want of skill on the part of the operator.

DR. JOSEPH TABER JOHNSON, of Washington, then read a paper on

TETANUS FOLLOWING OVARIOTOMY.

It was primarily the report of a very rare case. The patient was sixty years of age, and an abdominal section was believed to be indicated. A small ovarian cyst was removed, a drainage-tube being introduced, and all progressed favorably until the twelfth day. At that time symptoms of tetanus appeared which increased in intensity until the fifteenth day, when the patient died, with evidences of heart failure. Careful investigation was made, but it was believed that the author's hospital, in which the operation was performed, was in a perfectly sanitary condition. The author's horses were also without disease, and the author's hands were free from injury; the horses had not been driven by him for some days. This complication has reported only a very few times, and has usually occurred within a very few days after the operation. Bernouil recently announced his belief that it was communicated to human beings by horses, the medium being a bacillus. This should teach all who do abdominal sections to avoid the possibility of infection from horses.

DR. A. REEVES JACKSON, of Chicago, read a paper on

THE INJURIES OF THE BLADDER DURING LAPAROTOMY, INCLUDING A REPORT OF SIXTY-SEVEN CASES.

The data in the author's paper were collected from various sources. Some of the cases had been already published, but the greater number had been obtained through personal correspondence with the operators in whose practice the accidents had happened, and were now made known for the first time. Of course, it was admitted that the list was incomplete. Some surgeons manifest a reluctance to make known the various mishaps which occur in their operative experience, perhaps with the belief that a knowledge of them might injuriously affect their reputation among their colleagues. The author considered this an error of judgment. Surgeons should be honest as well as skilful, for their integrity would be quite as likely to receive recognition as their dexterity, and was certainly of greater value.

Considering the conditions under which bladder injuries may occur during laparotomy, it was not necessarily discreditable to any surgeon to meet with them, for they might not be due to any carelessness or lack of skill on his part. In many of the cases cited no possible degree of diligence could have averted the accident. Adhesions of the peritoneal surface of the elongated bladder to the anterior abdominal wall, frequently could not be known in advance, and their existence was only demonstrated after the viscus had been opened. The use of the catheter as a means of diagnosis was not always available, because the compression of the bladder against the pubes might prevent the introduction of the instrument beyond that point.

Certainly, this attempt should always be made in any case of suspected difficulty, and would seem to be even a proper and unobjectionable routine method.

Another useful precaution was to avoid prolonging the abdominal incision toward the pubic bone until the opening into the peritoneum had permitted the relations of the bladder to be ascertained. The mortality of the cases in which the bladder had been opened was large, being about thirty per cent., but this was due to the complicated and serious character of the cases in which the accident had occurred, the consequently increased length of the operation, and the greater danger from shock, rather than to the mere vesical injury.

The latter did not seem, in itself, to be very important as influencing the recovery of the patient, but should a fistula occur it would signify great discomfort, and also chagrin and annoyance to the surgeon. Inasmuch as the bladder was recognizable with more difficulty when empty than when full, it would be better in cases which presented doubtful features to commence the operation with the viscus more or less distended. When its position had become known, it might be emptied by an assistant.

As to the treatment, if an opening has been made it should be closed at once with a continuous suture of catgut or fine silk, the serous surfaces of the wound being inverted, and a permanent catheter being used for two days. At the end of that time it may usually be dispensed with. If the wound exceeds two or three inches in length the catheter should be retained three or four days longer; and in all cases the catheter should be retained as long as the urine contains blood. Should urine appear at the abdominal wound subsequent to the operation under conditions which would make it dangerous or inexpedient to reach the seat of the vesical injury, the catheter should be used continuously or at short intervals to lessen the quantity of urine which escapes through the fistula and thus aid in its closure. If the fistulous opening shows no disposition to close after two or three months, the edges should be freshened to the depth of half an inch or more and stitched together.

In exceptional cases it may be expedient to affix the wounded edges of the bladder within those of the abdominal incision, in the manner detailed by Thomas and others, but as this plan must interfere with the subsequent contractility of the bladder, it is not to be commended as a customary practice. The suturing and dropping of the bladder is the better method.

NEWS ITEMS.

The New Jersey State Medical Society.—At the late meeting of the New Jersey State Medical Society the following officers were elected for the ensuing year:

President.—B. A. Watson, M.D., of Jersey City.

Vice-Presidents.—James S. Green, M.D., of Elizabeth; E. J. Marsh, M.D., of Paterson; and George T. Welch, M.D., of Keyport.

Corresponding Secretary.—William Elmer, Jr., M.D., of Trenton.

Recording Secretary.—William Pierson, M.D., of Orange.

Treasurer.—W. W. L. Phillips, M.D., of Trenton.

Standing Committee.—T. J. Smith, M.D., of Bridgeton; D. C. English, M.D., of New Brunswick; and J. G. Ryerson, M.D., of Boonton.

After ratifying some changes in the By-Laws, and the adoption of some routine business, the meeting adjourned, to meet next June at Schooley's Mountain.

Association of Acting Assistant Surgeons.—The Association of Acting Assistant Surgeons of the United States Army held its first annual meeting at Newport, R. I., on Monday evening, June 24, 1889. Seventy-seven members have been enrolled. The following list of officers was elected for the ensuing year:

President.—A. Reeves Jackson, M.D.

Vice-Presidents.—J. L. Ord, A. J. Comfort, D. S. Lamb.

Treasurer.—R. J. Dunglison.

Registrar.—Benjamin L. Holt.

Recorder.—W. Thornton Parker.

Council.—H. M. Deeble, S. S. Turner, W. E. Sabin, H. R. Porter, J. P. Pratt, H. E. Turner, S. B. Stone, John S. Warren, S. O. L. Potter, E. W. Thompson, and John T. Nagle.

Applications for membership should be addressed to W. Thornton Parker, M.D., Narragansett Pier, R. I.

An Oxford Degree for Dr. Billings.—According to the *New York Medical Journal*, the University of Oxford will confer an honorary doctorate on Dr. J. S. Billings, U. S. A., in consideration of his valuable labors in connection with the Army Medical Museum and Library, the *Index Catalogue*, and the Johns Hopkins Hospital.

The Development of Cholera Bacilli.—If LOEWENTHAL'S experiments prove anything as regards the generation or evolution of the cholera poison in man, it is that certain states of the digestive system and of digestion are necessary for its production, and that if these conditions are not present, the comma-bacilli, which are presumed to be concerned in the manufacture of the virus, fail to produce it. Certain observations of Dr. D. D. Cunningham's, which are published in the most recent issue of the "Scientific Memoirs," edited by the Surgeon-General, would indicate that the development of these bacilli outside of the body also depends on favoring conditions.

"Dr. Cunningham conducted a series of experiments on the behavior of choleraic comma-bacilli in soil and water of various qualities, and he shows that, under ordinary circumstances, even in an endemic locality such as Calcutta, there is very little probability of their multiplying to any great extent, or persisting for any prolonged period in soil or water to which they may gain access. It further appears that this is due to their incapacity to hold their own in the struggle for existence to which they are exposed with the schizomycete, and other organisms normally present in the media, as, where the latter are sterilized, the persistence and multiplication of commas occur just as they would do in any artificial sterilized medium of suitable quality. Dr. Cunningham, taking these results along with others of a similar nature obtained by other observers as a basis, argues that, even if it should be granted that the comma-bacilli are the efficient cause of choleraic symptoms, they must be regarded as holding a very secondary place in the causation of epidemic diffusion of the disease, and that it is peculiarities in conditions of locality which must be regarded as of primary importance, seeing that without these the bacilli would neither be able to establish themselves in sufficient numbers and with sufficient persistence, nor be able, even could they do so, to affect the population in epidemic proportions. The practical conclusion which is arrived at is, that it is to improvements in local sanitation, and not to the enforcement of quarantine regulations, that we must look as a means of preventing the occurrence of spreading epidemics.—*The Indian Medical Gazette*, March, 1888.

The Nationality of Viennese Medical Students.—Of the 3185 medical students at present studying in the University of Vienna, 530 are foreigners. Of these, Russia furnishes 118; America, 105; Roumania, 78; Servia, 50; Germany, 46; England, 40; Bulgaria, 18; Greece, 13; Turkey, 10; Switzerland, 12; France, 5; Belgium, 8; Italy, 9; Sweden, 3; Holland, 5; Africa, 1; and Australia, 3.—*The British Med. Journal*, May 11, 1889.

The Pope's Physician.—According to the *Medical Record*, DR. GUISEPPE LAPPONI, a young and distinguished graduate of the Bologna school, has just been appointed body physician to his Holiness Pope Leo XIII., in succession to Dr. Valentino, deceased.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 18 TO JUNE 24, 1889.

By direction of the Secretary of War, the extension of leave of absence on surgeon's certificate of disability granted WILLIAM H, FORWOOD, *Major and Surgeon*, in S. O. No. 118, May 22, 1889. from this office, is further extended four months on surgeon's certificate of disability.—Par. 14, *S. O. 142, A. G. O., Washington*, June 20, 1889.

CORSON, J. K., *Major and Surgeon.*—Granted leave of absence for one month, with permission to apply for an extension of one month.—Par. 2, *S. O. 65, Headquarters Department of the Columbia.*

FISHER, WALTER W. R., *Captain and Assistant Surgeon.*—The leave of absence for one month granted by S. O. 30, *c. s.*, Department of California, and extended fifteen days by Par. 3, S. O. 37, *c. s.*, from these Headquarters, is further extended fifteen days, —Par. 1, *S. O. 41, Headquarters Division of the Pacific, San Francisco, California*, June 12, 1889.

By direction of the Acting Secretary of War, the following changes in the stations of officers of the Medical Department are ordered:

TEN EYCK, BENJAMIN L., *First Lieutenant and Assistant Surgeon* (recently appointed).—Ordered to Fort Leavenworth, Kansas.

GARDINER, JOHN DE B. W., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Leavenworth, Kansas, and ordered to Fort Reno, Indian Territory.

WYETH, M. C., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Huachuca, Arizona Territory, and ordered to Fort McDowell, Arizona Territory.

WOOD, LEONARD, *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Fort McDowell, Arizona Territory, and ordered to the Presidio of San Francisco, California.

Par. 3, S. O. 132, June 8, 1889, is so amended as to direct P. G. WALES, *First Lieutenant and Assistant Surgeon*, to report to Fort Huachuca, Arizona Territory, for duty, in place of the Presidio of San Francisco, California.—Par. 2, *S. O. 138, A. G. O.*, June 15, 1889.

By direction of the Acting Secretary of War, leave of absence for two months is granted to HENRY S. T. HARRIS, *First Lieutenant and Assistant Surgeon.*—Par. 13, *S. O. 140, A. G. O.*, June 18, 1889.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE MEDICAL CORPS OF THE U. S. NAVY, FOR THE WEEK ENDING JUNE 22, 1889.

BEARDSLEY, GROVE S., *Medical Inspector.*—Granted a year's leave of absence, with permission to leave the United States.

FEREBEE, N. M., *Surgeon.*—Detached from special duty at the Naval Academy, and wait orders.

ROTHGANGER, GEORGE, *Assistant Surgeon*.—Ordered to the Naval Hospital at Mare Island, California.

INDEX.

ABBE, intestinal anastomosis, 589
Abdomen, gunshot wounds of, 607
